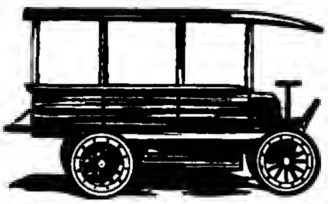
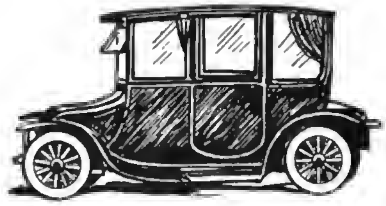
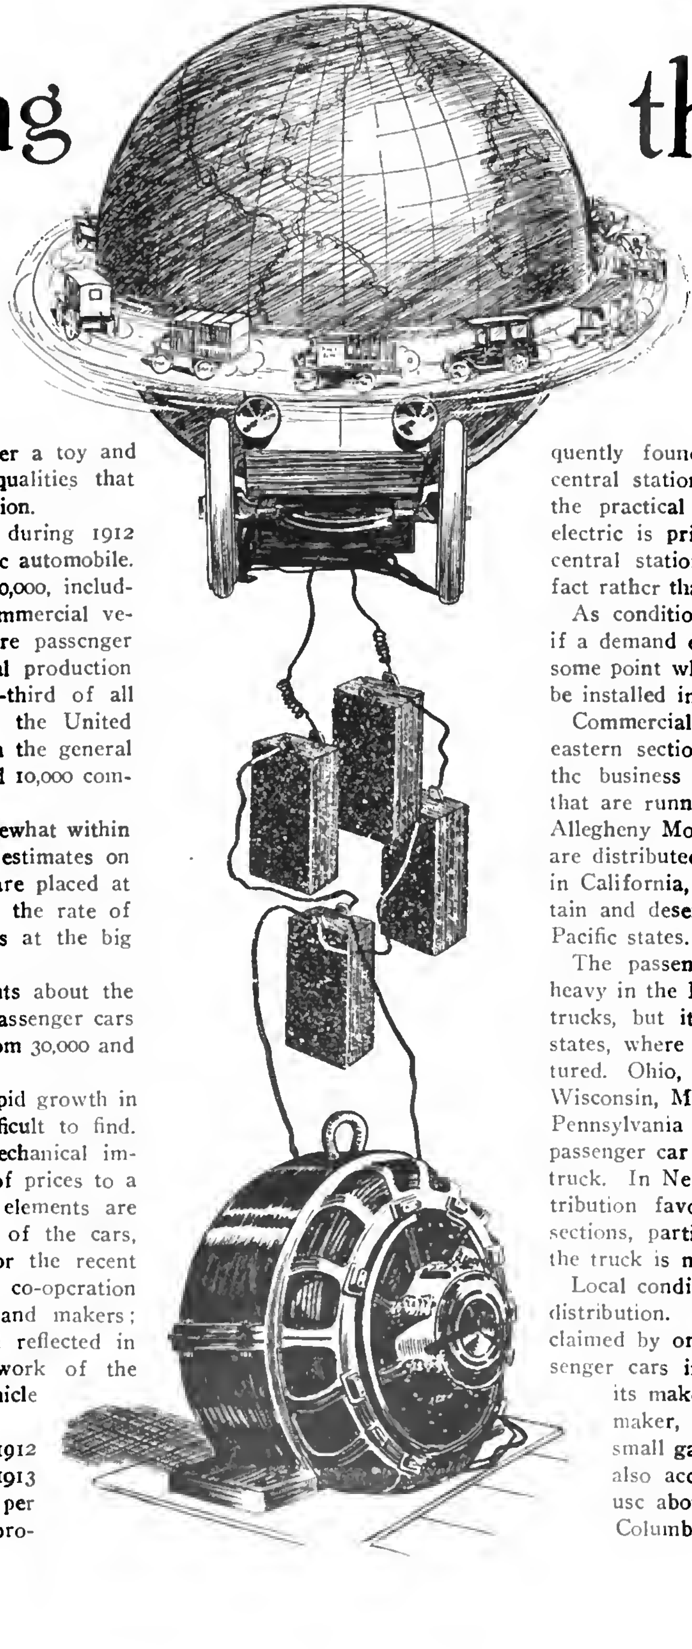
The Automobile



Electric Vehicle Issue



Surveying the Field



REACHING out into new territory; filled with virility; backed by the consumer and aided by the co-operation of central stations, the electric vehicle industry bounded into national prominence during the past year, particularly the past 6 months.

The passenger car is no longer a toy and the truck has shown service qualities that entitle it to respectful consideration.

Material progress was made during 1912 in the development of the electric automobile. Production was approximately 10,000, including both passenger cars and commercial vehicles, of which about 6000 were passenger cars and 4000 trucks. The total production of 1912 represents roughly one-third of all electric cars now in service in the United States, which may be divided on the general lines of 20,000 passenger cars and 10,000 commercial wagons.

These figures are probably somewhat within the actual facts, as are also the estimates on the production for 1913, which are placed at a total of 15,000, apportioned at the rate of two to one, with the passengers at the big end of the ratio.

In case that estimate represents about the actual output of 1913, the total passenger cars in the country will be not far from 30,000 and commercials 15,000.

The reasons underlying the rapid growth in the use of electrics are not difficult to find. Of course, there have been mechanical improvements and an adjustment of prices to a basis of value, both of which elements are important to the increased use of the cars, but the most potent reasons for the recent growth of the industry are the co-operation of central stations with users and makers; the acute demand for gasoline, reflected in its increased price, and the work of the national and local electric vehicle associations.

The electric vehicle output of 1912 and the estimated output for 1913 represent an increase of 125 per cent. in comparison with the production of 1911 and before.

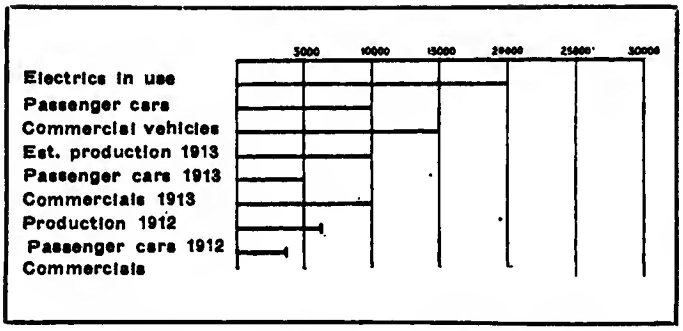
The distribution of electrics is almost as wide as that of gasoline automobiles, taking the states as a basis, but the electrics are limited in their use to the facilities for charging and consequently are most frequently found in the cities. Extension of central stations are being made steadily, but the practical demonstration shows that the electric is primarily a city car and that the central station situation is a result of that fact rather than a cause for it.

As conditions shape themselves at present, if a demand existed for a charging station at some point where there is none now, it would be installed immediately.

Commercial cars are in general use in the eastern section, probably 80 per cent. of all the business wagons manufactured to date that are running being in service east of the Allegheny Mountains. The other 20 per cent. are distributed through the central states and in California, with a scattering in the mountain and desert country, the south and north Pacific states.

The passenger car distribution is not so heavy in the East in proportion to that of the trucks, but it is far heavier in the central states, where most of the cars are manufactured. Ohio, Illinois, Indiana, Iowa, Missouri, Wisconsin, Michigan and the western part of Pennsylvania embrace the section where the passenger car is in larger proportion than the truck. In New England the proportional distribution favors the passenger car in some sections, particularly about Boston, although the truck is making progress now.

Local conditions have much to do with the distribution. For instance, in Cleveland, it is claimed by one manufacturer of electric passenger cars in that city that automobiles of its make outnumber those of any other maker, including the popular types of small gasoline cars. This tendency would also account for the large numbers in use about Detroit, Indianapolis, Chicago, Columbus, Denver and other centers.



Production and prediction in the electric field

According to central station data, the charging of trucks is by far the most profitable element of their business in proportion to the investment required. Figures have been produced showing that the truck business returns are 200 per cent. more in proportion than some other classes of business which the electric companies make determined efforts to secure.

In an effort to increase vehicle business generally, but specially with reference to the commercial trucks, the central station organization has taken up the matter of installing automobile departments at various points where there are considerable numbers of vehicles, or where the possibilities for introducing them are good. Separate departments for such work are conducted in New York, Chicago, Boston, St. Louis, Philadelphia, Newark and other large cities. The effect upon the industry has been astonishingly satisfactory.

The experience of the New Jersey Public Service Company is illustrative of the general situation. The automobile department has been in existence for 2 years. When it was installed there were a few trucks and about eighty passenger cars in its territory. Prior to that time the efforts to introduce the electric were only casual. The first effect of the initiation of the automobile department was to influence the manufacturers to increased efforts in marketing. On December 1, 1912, there were 191 commercial vehicles in service and forty more had been sold but not delivered, and the passenger cars had increased from eighty to 240. The kilowatt hour consumption for electric automobiles increased over 200 per cent. and the income over 100 per cent. The discrepancy between the consumption and the income is to be accounted for by the fact that large installations of automobiles owned by single interests or supplied from electric garages whose rates vary with the quantity of current used, get a lower rate for wholesale lots.

While the same proportionate showing has not been made in some of the other central station automobile departments, the general line results have been similar all over the country where tried.

The special value of the automobile to the central station is that it can be charged at times when other power requirements are small. Until such time as the automobile business shall constitute a constant load during the off-peak hours it will form an extra desirable element for the central stations. That limit is far in the future.

Vehicle Department To Educate Public

The efforts of the automobile departments have been directed largely toward educating the public to the advantages of the electric.

The Electric Vehicle Association of America, a national organization to encourage the use of the electric, has an active membership of eighty-three and a total membership of 317. Included on its rolls are seventeen manufacturers of electric vehicles; fifty-six central stations, and ten accessory manufacturers. Geographically the members are located as follows: Atlantic slope and gulf states, 228; middle states, seventy-two, and in the west, seventeen.

Headquarters are in New York, but active branches are maintained in Boston and Chicago.

Statistics on the electric industry as compiled in the past are fragmentary and of little practical value, but in the future the association announces that careful records are to be kept, tabulated and the results distributed where needed.

Standardization has occupied more attention during the past year than ever before. Particular attention has been given to the dimensions and type of the charging plugs. Uniformity in that particular is very important, as it is quite apparent that an electric automobile is valueless as a vehicle without a charge in its batteries, and the charge cannot be given if the standard plug of station will not fit the car in question. Limits of speed for pleasure and commercial cars have been advocated by some engineers, but as the speed quality is one of the superficial talking points of the salesman, it will be seen that standardization on that point will be difficult. During the year the most striking thing in the line of standardization has been toward battery capacity and wheelbase. A large majority of the manufacturers of passenger automobiles have centered attention on the 40-cell battery installed in a car with a 96-inch wheelbase. Several leading engineers think the 40-cell battery too large. Mechanically the tendency is to follow the recommended standards published by the Society of Automobile Engineers. Such standards have been followed by many of the designers.

The principal items in which efforts are being made to produce uniformity are: Battery arrangement to facilitate charging; the charging plug, receptacle and cable; lamp-capacity; speeds and tires, including fastenings.

Generally speaking, all these matters have been developed to a much greater extent in passenger car design than in commercial.

The work of the association is exemplified in what has been done in the matter of fire insurance. Prior to June the rate was $2 per $100 of insurance, including theft and valued feature clauses. A reduction of 25 cents per $100 was secured through the showing of the committees, and a further reduction of the same amount is now allowed where the theft element of the policy is waived. Liability insurance except in certain specified localities, covering personal injuries or death, can be had for $20, and property damage liability can be covered for $7.50.

Twenty-four Makers in Passenger Field

There are twenty-four manufacturers of passenger cars in the 1913 field. A majority of these manufacturers are grouped in and about Detroit, Cleveland and Chicago, and the electric passenger car propaganda has been preached more widely in those sections than anywhere else in the country. As a result of familiarity with the electric passenger car, its use is wider in the places where it is better known.

While the utmost luxury marks the construction and fittings of electrics, their advocates lay much stress upon their usefulness. Some of the main points urged by them are the following: The electric is a real horseless carriage. Therefore it can be used in excessive heat and in wintry weather without cruelty to horses. It can be left alone without causing worry to its owner. On account of the fact that the owner drives, he need waste no sympathy on the chauffeur, because there is none. No matter how many gasoline cars the business or professional man may have, his electric is most available for errands where waits are uncertain in length. For social service the fact that the car can stand without attendance and is ready for instant use is reckoned an advantage. Of course, all these things do not take into account the noiselessness, absence of dirt, ease of operation in traffic and the other things that have always been urged in favor of the electric.

Speed ranging from 18 miles an hour upward to 35 miles an hour is provided by the electric of 1913. Travel range is from 50 miles to 150 miles to the charge. The price of the average passenger car is $2,800.

The greatest emphasis is laid on the practical use of the electric in suburban service, and the men who make a business of selling say without exception that the electric has certain advantages in that field that are supreme. They do not say that the electric will displace the gasoline car for touring or distance work, but they do maintain that for certain classes of work their car is the best. In the large centers a new field of business has been opened up. During the past year considerable effort has been expended to place electrics with owners of one or more gasoline cars. The idea is that for social, theater and personal service the car fills a niche not completely occupied heretofore. Quite a measure of success has been achieved in this direction and fragmentary figures indicate that fully 50 per cent. of the electrics purchased this year were bought by owners or former owners of gasoline automobiles.

In the commercial vehicle field the chief development of the past year has been the extension of manufacturing. Aside from the increase in numbers, compared with preceding years, the most notable fact has been the introduction of larger models. There are now on the market five makes of 5-ton load capacity and numerous smaller trucks. These are used for transfer work by express companies, for delivery and transfer by breweries, etc. The range in load capacity at present runs from the small delivery wagon, capable of handling 1,000 pounds at a pinch, to ponderous trucks rated at 15,000 pounds capacity. The chief claims made for the electric truck are that it is certain and efficient in operation at moderate speed and cost and that for short haul work it fits well with almost any other type of transportation.

Seventeen Makers of Commercial Vehicles

There are seventeen principal makers of electric commercial wagons. They offer about sixty models of all kinds. The demand of users for particular bodies designed specially for their service has given rise to the practice of quoting chassis prices rather than prices for cars with bodies installed. Chassis prices range from about $1,000 to more than $5,000 and the bodies cost from $100 up to $1,000, depending upon size, type and style.

While some of the largest trucks made are equipped optionally with panel bodies and some of the 1,000-pound cars have open bodies, the general trend of practice is the opposite.

There are almost as many electric trucks of about 2-ton capacity in service as all other sizes together, according to estimates made by the Electric Vehicle Association of America. There are fully one-third of all the electric trucks in service, having a load capacity of about 3 tons. The remainder are divided between the large and small classes, with the latter in heavy majority.

The 1,000-pound wagon, meaning thereby the cars with carrying capacity of from 700 to 1,500 pounds are used for urban delivery service in growing numbers. The 1-ton electric has a wide variation of use. The standard 2-ton and 3-ton trucks are used mostly in transfer work, although city deliveries occupy much attention from these classes and express service in all its variety centers upon them. The larger sizes are freighters as a general thing, although deliveries by breweries, furniture removals and other heavy hauling with the retention of the delivery element claims many of them.

While the manufacturers usually make up some simple body style as a guide to the public, the widest sort of option is always given as to that type of equipment.

The length of the load platform is the best measure for the truck because the standard tread of the wheels limits width to the space between them except where the load platform is built out as far as the hubs, extending over the wheels. Often the main difference between trucks of 1,000-pound capacity and those of 1-ton load is in the greater length of the loading platform. In electric truck construction the power plant and running mechanism are so simple that it is possible to lengthen wheelbases to accommodate longer load platforms, without materially changing the chassis.

Of course, trucks designed to carry double the load of other trucks are built more strongly than the lighter type. In the matter of wheel and tire sizes this is particularly true. As an illustration of the point the practice of the General Vehicle Company, Lansden and Waverley shows that in the 1,000-pound truck these companies use 36 by 2 1-2-inch, 36 by 2 1-2-inch and 34 by 2 1-2-inch tires respectively. In each larger model they install a heavier tire until on the 5-ton truck the rear tire measurements are 36 by 5, 36 by 6 and 36 by 5 inches all dual.

There is a difference between batteries of the same number of cells, the rule being the smaller the truck the less ampere-hour capacity. Thus with the same number of lead cells in all models, the General Vehicle Company's ampere-hour range is between 104 and 324; the Lansden company with Edison cells, using the same number on all models ranges from 150 to 450 ampere-hours and the Waverley company's range is between 135 and 324.

The capacity of the batteries is by no means a guide as to the size of the trucks. With a very few exceptions the batteries of 1913 consist of forty-two or forty-four lead cells, or sixty cells of nickel-iron.

Amperage as a Measure for Truck Sizes

Regarding the operating range of the 1913 trucks it may be placed generally at between 30 and 60 miles to the charge. The average for the largest sizes is about 35 miles although 50 miles is claimed for one or two of the big fellows. In the small delivery cars 55 and 60 miles to the charge is claimed.

With one exception the cars of 1913 are equipped with left-hand steer. There is little new about the motors except the tendency to locate them at or near the axle, reducing the length of the driveshaft where drive by chain has been abandoned.

Chain drive is used by fourteen companies. Argo drives by bevel gear; C. T. uses worm gear on its two smaller models and spur gear on the remainder of its line; Walker drives by internal gears the motor being built as a unit with the rear axle; Waverley uses bevel gears for its small models and chains on the larger cars.

The use of I-beams for front axles increased largely since 1912, a clear majority of the makers now making use of such axles.

What has been said about individual needs in body construction applies as well to chassis and many companies make a specialty of filling orders for trucks of extra capacity. The General Motors Company and the General Vehicle Company each make a 15,000-pound wagon, while intermediate sizes can be had from almost any of the manufacturers in addition to their regular lines.

Summed up, it may be said that the commercial vehicle branch of the electric vehicle industry is better seasoned; that the few structural changes appearing this year are mechanical refinements; that the power is greater and range of operation wider in actual practice and prices are steady throughout the line. The tendency toward apportioning the load in direct ratio to the tire sizes of the front and rear wheels and between the right and left wheels, front and rear, together with the improved spring suspension will have its effect on tire service and the life of the mechanism generally.

Returns from fifteen cities taken at random throughout all sections of the country give the general trend of the distribution, covering over 25 per cent. of all the cars in use.

Electric Vehicle Association of America

Brief History of the Organization, Its Aims, Activities and Methods — What It Has Accomplished

By Arthur Williams

President Electric Vehicle Association of America

THE Electric Vehicle Association of America was formally organized on September 1, 1910, for the purpose of promoting the adoption of electric trucks and pleasure vehicles. Up to that time manufacturers of current-propelled cars had found the cost of production high, owing to comparatively small sales; makers of batteries had, consequently, too small a market for their wares; while central stations, seeing but little demand for current for charging, had been setting the price for such supply at figures which tended to discourage the use of electric motor cars.

Accordingly, twenty-nine delegates of these three distinct interests, realizing that a co-operative campaign to bring the electric vehicle into greater public favor would be of far-reaching value, formed the Electric Vehicle Association. In 2 years its membership had swelled from twenty-nine to 335, and it at present represents companies having a combined capital account of more than $500,000,000. While in the beginning the activities of the association were confined principally to New York City, today its influence, as well as its membership, has spread all over the United States, manifesting itself in thriving branches at Boston and Chicago with newly formed centers at Philadelphia and San Francisco.

Having thus outlined briefly the formation and internal growth of the Electric Vehicle Association of America, it is best to turn at once to the more important questions: What has it accomplished? What methods have been employed? Why does the association believe in electric vehicles? What does the association hope to do in future?

First in importance comes the test query as to definite results already obtained. In New York City between July 1, 1911, and July 1, 1912, the number of electric vehicles in use increased 45 per cent. In St. Louis during the first 6 months of 1912 one central station reported a gain of nearly 37 per cent. in revenues from charging type of car; and in Chicago an authority on electrical affairs estimates that electric trucking has grown 400 per cent. in the last 2 years.

These examples, to which others might be added, serve to show the remarkable gains which the electric car has recently made; and these facts are all the more worthy of note, since it is well known that gasoline cars, especially for business uses, have been pushed forward rapidly during the same period. Now, for this spurt in the electric vehicle industry, the Electric Vehicle Association of America holds itself in a large measure responsible. The leap forward is, in the belief of many motor car builders and central station managers, a direct and comprehensive result of the association's activities.

Besides doing much to spread belief in current-driven vehicles, and thus hastening their adoption, the society has also turned its attention to making provisions for greater convenience in operating cars. As a step in this direction it has brought about the compiling of lists of charging stations so that car owners may find them without difficulty. It has also urged the adoption of a uniform sign throughout the country, to indicate battery-charging stations, and is at present designing such a sign. It has also counseled the multiplying of these replenishing stations so they may be within easy reach of all vehicle owners in large cities. The association has succeeded, besides, in standardizing the charging plug so that it may be used for various makes of cars.

We come next to methods of work. Those pursued by the Electric Vehicle Association may be summed up under the following heads: investigation; exchange of ideas; and publicity, this last term including both direct and indirect advertising.

In order to investigate various problems, members of the organization are divided into committees such as those on insurance, standardization, rates and charging stations, and operating records. A rapid interchange of ideas and information is brought about at the association's monthly meetings. At each of these a paper is read and discussed, being afterwards published in *The Central Station*, the association's official organ.

The publicity work of our organization is aimed directly at the general public. When the Electric Vehicle Association was formed people in general did not know enough about the advantages of electric vehicles. They were sceptical; they had heard that battery-driven cars and trucks were impractical. It was to combat this widespread ignorance that a co-operative educational and advertising campaign was planned in the fall of 1910. Its scope was to be the advertising of electric vehicles in general, without regard to special qualifications of various makes. The work thus started has been so emphatic a success that a sum of $50,000 is now being spent by the publicity committee, and further funds will be ready as soon as they are needed.

No society could push with enthusiasm a cause in which its members did not believe. It goes without saying, then, that the Electric Vehicle Association of America believes heartily in electric vehicles. However, it is exhibiting no blind, unreasoning faith, for it does not urge its wares upon the public for all purposes. It recognizes, for instance, that the gasoline car is preferable for long-distance hauling. But it also knows, from intimate experience, that electric trucks and pleasure vehicles, are fitted to excel other automobiles for city use, delivery service and short-distance hauling. For these purposes it has unlimited faith in the electric motor car, because of the latter's dependability, ease of operation in crowded thoroughfares, simple driving mechanism, economy of maintenance and the reduced fire-risk incurred.

In looking toward the future, the Electric Vehicle Association of America expects to bring about a stronger organization of its own forces with branches in many of the principal cities of the country. Besides working continually for the more general use of electric vehicles it will also bend its energies toward the further standardization of cars, toward improvements in batteries and the establishment of more charging stations, not only in cities but also on routes connecting large towns. Moreover, it prophesies an increasing urban and suburban use of electric vehicles, owing to more generally diffused knowledge of their merits. And this, it is expected, will lead to the gradual disappearance of the horse from city streets.

It has been estimated that the amount of trackless hauling in this country is sixteen times as much as that carried on by railways, and of this, 80 per cent. is done in cities, where electric propulsion could accomplish it more safely, quickly and economically than horse-power. When this becomes an established fact it ought materially to lessen the price of goods to the ultimate consumer.

Future Bright for Electric Automobile

Field of Usefulness Is Widening in City and Suburban Service with Greater Travel Radius

By Manufacturers

Sales Managers Express Views on Subjec

PREACHING the propaganda of the electric has proved to be the most efficient means adopted so far to widen the use of such automobiles. The simple fact that they are more widely used in territory adjacent to the places of manufacture proves that those who know them best like them best.

Of course, from the viewpoint of the manufacturer the other essentials have been developed and the following symposium by leaders in the industry indicates the uniformity of opinion.

They bring out the special elements covered by the electric and take an optimistic peep into the future.

Suburban pre-eminence is claimed throughout the industry. The attainment of the real horseless vehicle is asserted. The installation of fleets of electric trucks is pointed out as an indication of the attitude of large consumers toward the commercial vehicle. The elimination of the chauffeur generally in the passenger car field is reckoned as a credit item. But through all the statements runs the plea for more thorough education of the public; better garage facilities and concert of effort by all elements associated with the industry.

Fine for Suburbanites—Brand

IN reference to the future of the electric car covering a period of the next 5 years, this is rather in the realms of prophecy except as we analyze same from present and past conditions. The constantly increasing difficulty of transporting the street cars' patrons of the larger cities with comfort to the passengers is impressing the desirability of electric brougham ownership on an increasing number of people. There is no immediate remedy in sight for radically bettering public passenger conveyance conditions, even with material additions to surface and subway lines.

While the American business man of means may submit to discomfort in his own travel to and from his office instead of avoiding the discomforts of public conveyance travel by electric car ownership, as soon as it is impressed upon him that these discomforts as far as his family are concerned can be avoided, he is very likely to become numbered among the many satisfied owners of electric cars.

Suburban residence is more and more attracting people of means who are in position to afford electrics. A drawback, however, of suburban residence to those dependent upon public conveyance transportation, is the infrequency of the train or car service.

Good roads agitation that has been going on the last few years has resulted in splendid suburban roads for considerable distances around large cities, and over these roads an electric properly equipped with batteries is capable of traveling from 70 to 100 miles per charge. It is an admirable means of transportation for the suburban resident, making possible trips to and from the city at will, giving to suburban electric car owners means of keeping in touch with their circle of city friends and acquaintances, and permitting the advantage of city shopping and entertainment, all independent of train schedules and train service.

Professional men and women desiring a dignified conveyance of such simple mechanism as to permit of operation without mechanical skill, are rapidly becoming electric car owners.

The many city transportation uses for which an electric is adapted, make this type of car one whose ownership is a pleasure. All of the above conditions are with us to-day, and they all tend towards increased sale of electric cars.

With the rate of growth there has been in the sale of electrics during the last five years, and with the showing of utility and good service that is being made by them, the next 5 years will take care of themselves.

There is no doubt that there will be improvements in electrics and cars will be refined and bettered from time to time. Just what these improvements will be, the future will develop.

The establishment of better garage facilities and the increased number of men whose services can be obtained for intelligently taking care of electrics and advising owners in reference to taking care of batteries and operating parts of the car, insure better service of electrics in general, and a constantly increasing number of enthusiastic electric car owners.—FREDERICK A. BRAND—The Broc Electric Vehicle Company, Cleveland, O.

Field Limitless—Henderson

¶ The field of the electric for city and intercity use is practically limitless. Such a statement might have seemed absurd to the minds of most people 3 years ago, but so rapid have been the strides in the development of storage batteries, the manufacturer meanwhile keeping pace in the development of the mechanical parts of the car, that their use in city and suburb 5 years from now will be universal throughout the United States and Canada is a logical conclusion.

One of the most potent factors in promoting the greater popularity of the electric is the fact that the price of current is steadily decreasing, while the cost of gasoline is constantly soaring upwards. The electric at the present time is the most economical means known for city and suburban trackless transportation in both the commercial and pleasure fields. The most notable expression of confidence in the electric truck as an economical and efficient means of transportation is the purchase of the electric truck fleets in enormous quantities by the various express interests of the country. After the most searching investigation and long years of test and try-out, these large transportation interests have adopted the following rule for the introduction of motor equipment. For all city delivery purposes, the electric is used exclusively. For suburban service which involves the long hauls and rough road work the gas truck is being used. Nowhere have the two distinct fields of service for the gas and electric been made more apparent than by the use to which the two types have been put by the express companies.

It is the performance of the cars themselves which has won a greater popularity for the electric as a necessary adjunct to the social activities of the men and women of this country. In the first place its qualities of inherent simplicity and absolute reliability have won the confidence of everybody. The older members of the family who use an electric know that it is a car which is as safe to operate, and even safer, than the old family horse. It has the added advantages that it is no plug and can go as far in a day as one cares to ride.

Charging facilities are readily installed and at no very great expense, so that it is perfectly possible for the purchaser of an electric to take complete care of the car himself, charging apparatus being so designed that it automatically shuts off when the battery has been given sufficient charge. The electric becoming more universal in the large centers of population has afforded the opportunity to the manufacturers to give a more perfect service to the owners so that nowadays there is scarcely a city of any consequence in the United States which has not complete power facilities and at least one electric service station which renders complete service to a large number of users at a nominal monthly cost. This system relieves the owner of all responsibility for the proper operation of his car.

In conversation the other day with a man who is closely in touch with the development and plans of the larger electric current producers in the country, he made the statement that he confidently looked forward to the time within five or six years when electric power companies would have the principal highways of the United States spotted with power sub-stations at frequent intervals where it would be possible for the electric car tourist to exchange his discharged battery for one freshly charged and proceed on his way. This statement at first sounded to me somewhat highly colored and imaginative, but upon sober second thought I can conjure up no really plausible argument why such a system could not be very actively worked out in the next few years to come to the great profit of all concerned.—O. B. Henderson—The Baker Motor Vehicle Company, Cleveland, O.

Perfect the Batteries—Woodward

¶ A very wide field of usefulness awaits the electric pleasure vehicle, and one which it is ready to meet just as soon as the public wakes up to the modern electric's adaptability to its requirements. When people realize how far an electric car will travel on a charge, how reliable it is, how free from disorders of all sorts, how simple and easily handled, and withal how speedy and efficient under all conditions, the electric pleasure car will quickly come into its own.

City women have always been the largest users of the electric. There is bound to come a still greater demand from this source with a better understanding of the convenience and simplicity of the modern electric car.

Business and professional men are sure to take advantage of the great facility offered by electrics for their trips about the city. There is a tremendous field in this direction when we can overcome the prejudiced belief that the electric is only a woman's car.

At its present stage, selling electrics is largely a matter of education. The public do not know what an electric car of modern design will do, nor how easily it will do it. When they find out, we will not be able to build electrics fast enough.

The future field of the electric pleasure vehicle, outside of the larger cities and towns, will depend largely upon the men who are perfecting the storage battery. With lighter and more powerful batteries, there is almost no limit to the field which the electric vehicle of the future may rightfully claim as its own.—O. J. Woodward—Woods Motor Vehicle Company, Chicago, Ill.

Future Is Bright—Krueger

¶ If the last 20 months can be in any way considered a barometer as to the possible growth of the electric car business, it certainly is destined to become a very important factor in social and industrial life in cities. The field of the electric today is practically confined to cities of 7,500 or above in population, although with the advent of popular-priced cars, the smaller cities have shown a remarkable demand. Cities are now buying cars, where very few if any were in use before. The fact that the prices in some have been reduced, and popular-priced cars have been marketed, opens up a new and undeveloped field in the smaller cities. Of course there is a natural increase that comes with the general increased understanding of electrics, but there are three elements which have probably contributed more to the increase in the electric business than anything else, and they are as follows:

1—The general understanding on the part of the public as to the care and operation of electrics.

2—The decrease in the first cost of electrics.

3—Revisions and improvements in mechanical construction with corresponding increase in efficiency.

The possible field for inter-city use for electrics where the roads are good, and the radius does not exceed 20 miles is almost unlimited. Farmers are booking with the electric for farm-to-city use.—C. F. Krueger—Standard Electric Car Company, Jackson, Mich.

To Be Supreme City Car—Reed

¶ The electric automobile was looked upon by the public as a somewhat expensive toy 5 years ago, a luxury without any well defined place or purpose. Today it occupies a prominent place in industrial and social life.

And its future?—A comprehensive study of the evolution of the electric, the development of public opinion, the growth of distribution and sales, leads the writer to believe that in the future this vehicle is destined to be the supreme city car.

Statistics taken in twenty-five of the largest distributing points in the United States show that out of the total number of electric cars running in these localities, 25 per cent. to 60 per cent. have been sold during the past 15 to 18 months. Everywhere manufacturers and distributors are enthusiastic over the future possibilities of this industry.

The gratifying future of the electric is due to the present success in destroying dangerous prejudices. Until 2 years ago, the general public and a large proportion of the automobile dealers who play a very important part in ultimate distribution, were not acquainted with the tremendous advantages of the electric. They voiced imaginary objections, among which were: "It will not climb hills"; "It will not give enough mileage"; "It has no speed"; "Its cost of maintenance is too high." These charges are disproved by fact and experience.

No better evidence can be given of the ability of electric cars to climb hills than the electrics now running in such cities as Seattle, Cincinnati, Pittsburgh, Kansas City and other towns of similar topography. In these cities 45 per cent. of the total number of cars in operation were sold during the past year. Today the electric motors and batteries used are a vast improvement over the designs of 6 or 8 years ago. Motors are now built to withstand the most severe road conditions, excessive overloading and to perform at a high efficiency above their normal rating.

The modern electric will render an eminently satisfactory mileage. We must remember this vehicle is strictly a convenience and is designed with reference thereto. The designing of an electric for mileage in excess of what is actually required for its purpose is simply wasted.

High speed is obtainable in modern electrics. It will be of interest to the reader to know that the fastest automobile mile, some years ago, was made by an electric. It has the speed and power proportionate to its use and natural service.

The operating cost of a well-equipped electric is considerably less than is usually thought to be the case. There is an economic feature to be considered. It eliminates the necessity of a chauffeur. You have all the convenience and luxuries of a limousine without its attendant expense.

The barriers have been swept away. The electric car is no longer a victim of misunderstanding. When a product has killed prejudice and enlightened public opinion, its future success is assured. The electrically-propelled vehicle has won its first and greatest battle. The next decade will see the electric pleasure car holding unchallenged its position as the ideal city car.—Penrose Reed—Chicago Electric Motor Car Company, Chicago, Ill.

Insurance from the Electric Viewpoint

Rates Recently Cut by Companies As Result of Decreased Liability To Accidents of All Kinds

By Carl H. Clark
Insurance Adjuster

WHEN the matter of insurance of automobiles was first brought out some years ago, it was treated rather lightly by owners, dealers, and even by those insurance companies which did not at that time write it. Conditions at present are, however, far different. There has been a great increase in the number of insurance companies writing it, and an enormous increase in the number of cars insured.

It was once a very common saying that there is nothing about an automobile to burn, but experience has shown both owners and underwriters that cars of all descriptions can and do burn. The saying is therefore rarely heard now, and the insurance of automobiles has become very firmly established. It is almost the exception to see a car of recent make and of some value which is uninsured, and, in fact, so general has insurance become, that cars are offered for insurance continually, which, from their type, age, ownership or other conditions, are not insurable.

While it is not possible to describe in detail within the limits of a short article all of the various forms which the policy may take, the general terms and intent of the policy may be described. The automobile fire policy may be divided into two general classes, namely, (a) the full value form, and (b) the non-valued form. Under the former (a), the value of the car insured is determined and agreed upon when the policy is issued, and remains without reduction during the life of the policy. In the event of the destruction of the car there can be no question as to the amount payable, this being the insured value, without regard to the actual value at the time of the fire. The policy covers against fire in the general sense, arising from any cause whatever, whether external or internal. In case of damage this form of policy allows the replacement of destroyed parts with new without regard to any depreciation from use. Damage to the car while being transported upon any conveyance upon land or water is also provided for, as well as the loss by theft of the car or any of its equipment in excess of $25 in value. The theft clause is also construed to cover damage to the car while in the hands of unauthorized parties. Losses under this clause are very numerous, especially in the large cities; some cases occur where a car disappears completely, and there are frequent cases where cars are recovered in a damaged condition.

In the non-valued form (b), the value of the car and the parts thereof is not stated, but is left to be determined at the time of the loss. Losses are presumably adjusted on the basis of the value at the time of loss, taking account of depreciation. As the automobile is probably the least stable in value of any kind of property, there are naturally some difficulties in determining its value at a particular time. This form of policy does not as a rule carry the theft and transportation features, although custom differs somewhat in different States. The latter form of policy, as might be expected, costs less than the former.

Attached to the fire policy there may be a collision clause, as it is termed, which covers the car against damage sustained by collision with a moving or stationary object. This, again, may appear in two forms, the full coverage, which pays for all claims in full, and the $25 deductible, in which this amount is deducted from each claim. In other words, only the excess over $25 is payable. The latter form is the less expensive, as it has the effect of eliminating a large number of small claims, which would total to a large amount. In some States there may be attached an additional clause covering against collision damage done. This protects the owner of the car against liability for damage done by the car to the property of others, or the property damage.

There is also the liability policy, covering the liability of the owner for personal injuries inflicted on others by the car. This form of policy, as usually written, covers injuries to one person up to the amount of $5,000, and up to $10,000 if two or more persons are injured. These limits may be doubled if desired. The insurance company also pays the cost of defending all suits for damages. The property damage clause above mentioned is very often written in connection with the liability policy, as it is of the same general nature.

With reference to the rates of insurance, those for gasoline cars are figured on a sliding scale, which is based on the age of the car, original price, and amount insured. The rate for electric vehicles is a flat rate. Without quoting figures, it may be said in a general way, that the rate on electric vehicles is about one-half that charged for the gasoline car. Since the rates are based on experience, this may be understood to mean that the losses have been less in proportion than on gasoline cars. In fact, there has been a reduction of the rate on electric cars within the last few months. On the other hand, if with the increased use of electric cars, both for pleasure and business, the losses should proportionately increase, it might be expected that the rate would also increase.

The favorable experience with electric vehicles may be accounted for by several reasons. First, and probably of greatest importance, the nature and construction of the electric render it much less liable to fire than in the gasoline car, where inflammable gasoline is used. The electric is generally used for a certain definite purpose and over short distances, and it is thus less exposed to fire risks, and on this account also it is less likely to be driven by careless or inexperienced persons. On account of its low speed, it is less shaken up, with the consequent loosening of joints and connections. The low speed and the ease with which it can be controlled also make it a favorable proposition as regards the collision and liability insurance.

It may be of interest to note some of the most common causes of fires in electric cars. These seem to fall somewhat naturally into a few definite classes:

The most common cause seems to be the overheating of the resistance coils by the throwing on of the current while the car is at rest. The primary cause is the accidental movement of the control lever after the car has been stopped and the brakes set. Sometimes the control lever is thrown from neutral into the first speed by catching in the sleeve or skirts as the operator is leaving the car. The low-tension current used in the electric car has great heating effect, and the current under the above circumstances soon overheats the resistance coil, causing damage. Cars have been known to travel a few feet unobserved after the current had been accidentally turned on, bringing up against a wall or snowbank, with the same result. Care should be taken in leaving the car to see that the control lever is in neutral, and the plug removed. This latter precaution will in a large degree prevent also the theft of the car.

Engineers View Electric Standardization

ALEXANDER CHURCHWARD, H. H. Rice and E. W. Gough summarize what has been done, and outline some of the things that ought to be accomplished to produce passenger and commercial electrics in conformance with some established basis of uniformity. Mr. Churchward says that to-day standardizing the speed of the electric is the aim. For commercials he believes it should range from 13 miles an hour to 6.5 miles an hour in decreasing ratio to the load capacity. Mr. Rice holds that voltage, batteries, lights and plugs limit the field for uniformity, while Mr. Gough takes the position that parts and equipment of all sorts are susceptible to standardization which is required with more force even than in gasoline practice. He specially points out that electric current distribution is uniform and that the vital parts of car equipment should be harmonized with the established rules.

STANDARDIZATION in the electric pleasure and commercial field is an important factor. I advanced the cause of standardizing voltage of various sizes and types of vehicles 1 year ago, and much progress has been made. Today nearly all of the 1912-13 vehicles will be equipped with batteries the charging voltage of which will be from 78 on the smaller pleasure or passenger cars to 110 on the various sizes of commercial vehicles and the larger types of pleasure or passenger cars.

Today standardizing the speed of the electric vehicle is the aim. The speed of these vehicles has been increased from year to year, and the real cause of this is not that the engineer of any one company has found some new battery, motor or tire, but because the salesman finds it easier to sell a car that will travel faster than that of his nearest competitor. Now the real claim for the electric pleasure vehicle is that it is so simple, reliable and easy to operate that any woman can operate it. But when you stop to consider that one of these glass-inclosed vehicles weighs approximately 1.5 tons with passengers, and is capable in some cases of making 25 miles an hour on good level roads, do you think that the speed is too high for the vehicle to be properly controlled by a woman? I consider 20 miles an hour very fast, yet the braking strain is 56 per cent. greater at 25 miles an hour than at 20. And I have noticed that in many cases the braking mechanism has not been increased in proportion to the increase in the speed of which the vehicle is capable.

I suggest the following speeds as standard for electric pleasure vehicles, and in presenting these would say that I have talked the matter over with the different manufacturers and the following speeds have been selected as an outcome of these conversations:

Closed types, Coupé	Open Victoria types
19 M.P.H. pneumatic tires	20 M.P.H. pneumatic tires
18 M.P.H. solid cushion tires	19 M.P.H. solid cushion tires

In order to determine the amount of electric current consumed by electric vehicles operating at different speeds, I conducted a series of tests and to obtain the desired accuracy attached a special graphic recording instrument to the vehicle which registered simultaneously the amperage and voltage at the motor or battery terminals, depending upon connections made; revolutions of the front wheels and a chronograph-meter attachment so that the time and number of revolutions are recorded. This instrument, in addition to giving the exact reading at any one time, is valuable for making acceleration tests as it shows the variations in volts, amperes and speed during the time required to move the vehicle from rest to full speed. From these tests it is apparent that the power required to drive an electric pleasure vehicle rises very rapidly as the speed is increased over 17 or 18 miles per hour.

It is equally essential in the commercial vehicle field to take recognition of speeds, and I have recently taken this matter up with a number of manufacturers and a compilation of the speeds they suggested for electric commercial vehicles of various capacities is given herewith:

Vehicle Capacity	Speed M.P.H.
1000 Pounds	12 to 13
2000 Pounds	10 to 11
3000 Pounds	10
2 Tons	8 to 9
3 Tons	7 to 8
4 Tons	6.5 to 7.5
5 Tons	6 to 7
6 Tons	6.5

A 3-ton truck, to compete successfully with horses, does not have to run at touring car speeds. The average speed of a 3-ton horse-drawn truck is 2.5 miles per hour, and the mileage not over 12 to 15 per day. Therefore a 3-ton truck running at 7.5 miles per hour will compete very successfully with a horse-drawn vehicle and its maintenance cost will be low. Therefore the maximum speeds must be kept down to such a point that the electric vehicle will continue to hold the enviable position it does today; namely, that for city work and short hauls it is the cheapest and most reliable method of mechanical traction.—ALEXANDER CHURCHWARD, Boston, Mass.

Standardize Voltages—Rice

¶ The standardization of electric pleasure and commercial vehicles has been considered at several meetings of the standardization committee of the Electric Vehicle Association of America.

Standardization is a good thing, but it is, I should say, of necessity, limited in its mechanical side to the adoption of the standard sizes of bolts, nuts, threads, etc., already adopted as standard by the A. L. A. M. and the S. A. E. committees. **Electrical standardization is limited, I believe, to the voltage of motors, batteries, and lights, to the charging plug, and perhaps to the running plug,** provided the car has other means of individual locking, such as a Yale key.

The voltage standard is necessarily regulated by the voltage supplied by the central stations and by the physical properties of the battery. The standard direct voltage is 110 or multiples of it, hence one standard, at least, would be approximately forty to forty-two cells as a maximum number which can be charged from a 110-volt direct current. This would require, naturally, a motor of the same voltage.

For those engineers who feel that the best compromise in designing is to use a smaller number of cells, I think thirty is a good stopping point, and might be standardized, giving the engineer that option. This is a good standard too, because the motor to go with this lead battery voltage could be used with a sixty-cell Edison battery, which is about the highest voltage Edison which can be charged off 110-volt circuit.

If it were thought that other standards were needed where indoor trucks or light pleasure vehicles did not require so much power, still other standards might be set of twenty-four and sixteen cells, the motor voltages for all being correspondingly 80, 60, 48 and 32 volts.

It will be understood, of course, that it would be quite possible to keep the 110-volt standard on a car requiring a very small battery, but this would make it necessary for the battery people to build very small cells and increase the variety of battery plate and jar sizes to such a number that an attempt to standardize solely on 110 volts would increase the confusion in the batteries.

With Edison, voltage standards would be the same as above, but would, of course, require different number of cells than the lead battery for the corresponding voltage.

The desirability of a standard charging plug and receptacle, so that any make of car could be charged without difficulty, or any make of car in a strange garage when in another part of the city or going across country, is too apparent to need comment.

The running plug or switch key, if not used in combination with a definite lock for protection against meddling, might very well also be standardized, principally for the sake of garages where various makes of cars are stored. This latter, however, is of minor importance, and in fact it would be probably difficult to get uniform adoption of such a key.

Lamps, of a necessity, would be standardized if the battery voltages are standardized, but the standards might and should prescribe certain approved makes of sockets and size of sockets, as for instance, Ediswan candelabra base, so that the owner could readily find globes to fit his lamp.—Herbert H. Rice—The Waverley Company, Indianapolis, Ind.

Standardization Is Necessary—Gough

¶ **The necessity for the standardization of parts and equipment of electric vehicles, both pleasure and commercial, is even more apparent than the standardization of gas car apparatus,** now being so admirably conducted by the S. A. E. Each vehicle propelled by a gasoline engine is in a sense independent, provided parts can be obtained from its maker, as fuel, oil, etc., are obtainable almost universally. The electric vehicle, however, must of necessity come back to general charging points, and this in its broadest sense need not be public garages, but eventually they must be charged from common electrical distribution systems.

Since practically all the electrical distribution systems are standardized in this country it is evident that the heart of the electrical vehicle, namely, the battery, should readily adapt itself to this standardized service.

Treating broadly the various elements in the electric vehicle which could be standardized to advantage, I submit the following:

Batteries—The arrangement of the battery should be such that it is easily charged from the ordinary 110 to 115 volt circuit, this voltage being almost universal. To obtain economy it is obvious that the largest number of cells of battery permissible with this charging voltage should be used, otherwise energy is wasted as heat in rheostats, etc.

Charging Apparatus—The charging plug, receptacle and cable should, as far as possible, be uniform. While it may not be possible at this time to adapt a universal charging plug suitable for both small pleasure vehicles and very heavy trucks, it should be possible to cover the entire field with not more than two plugs, etc. Under such an arrangement any garage could care for any make or size of vehicle as far as charging is concerned.

Lamps—The electric lamps should be standardized, particularly as to the base and voltage. The adoption of standard lamps will enormously reduce confusion and disappointments to the owner.

Speeds—The ultimate speed of any electric vehicle, being largely a fixed quantity for a given road and load condition, it would seem highly desirable to standardize for various sizes, capacities, etc., bearing in mind that a vehicle which is too slow may interfere with congested traffic as much as one which is too fast. Much able work has already been done along these lines by the Electric Vehicle Association of America.

Tires—For pleasure vehicle work this subject has already been largely covered by the S. A. E. as the general mounting of the pneumatic tires is the same for both gas and electric vehicles.

For **commercial vehicles, however, there has been practically nothing done which could be considered standard.** Since the tire has a very great bearing on the electrical energy required from the battery, too much effort cannot be exercised toward the use of a standard tire having high efficiency universally obtainable, easily mounted and easily maintained.

There are many other parts of refinement which can hardly be taken up in detail in this space, such, for example, as the standardization in commercial vehicles of weight ratio to draw bar pull, ratio of weight to capacity, etc.

The electric vehicle industry is only in its infancy, and a few years more will show vast changes in details tending toward standardization of all classes of vehicles and consequent bettering general service.—E. W. Gough—General Vehicle Company, Long Island City, N. Y.

What the Distributors Say About the Field

"A WELL-EQUIPPED centrally located general garage for electric cars would do more to educate the New York public to the advantages of the electric automobile than anything else," said W. R. Chandler, vice-president of the Holt-Chandler Company, handling the Flanders in the metropolitan section. "I favor the selection of a large plot of land in upper Broadway and the erection of an adequate garage building so located that the passing throng shall be able to see cars entering and emerging from the building; cars standing on the floors; cars being charged, all visible through large expanses of plate glass. The fact of the matter is that the New York public knows little about the electric passenger car and what little it thinks it knows is largely erroneous. The actual, physical sight of electrics at the source of power supply would frequently raise the one question in the minds of possible buyers that the electric fraternity wishes to implant: If the electric in use can be handled, run and charged like that; why should not I have one?"

"The electric passenger car is not a rival of its gasoline prototype in the field of touring and distance work," said Nathaniel Platt, sales manager of the Baker Motor Vehicle Company in New York. "It is, however, the best automobile vehicle for suburban work; for service in heavy traffic and for social and individual use where the chauffeur is not required. There are about 2,000 electric automobiles of all sorts in operation in New York, the charging of which is a valuable element in the business of the central stations. The peak of the load usually occurs about 5 o'clock in the afternoon."

"In direct competition with the gasoline car, the electric is now bidding for city and suburban business," said Cloyd Y. Kenworthy, representing Rauch & Lang in New York and vicinity. "The electric is not simply a woman's car. It is an automobile of general usefulness. Physicians are taking it up for professional service and I need not recount the established facts concerning the electric further than to say that if the car is good for the doctor's purposes, the last futile argument against such automobiles disappears."

Electric *for*

GREATER-CAPACITY batteries; longer wheelbases; larger and lower bodies; together with a host of minor improvements mark the difference between the electric passenger vehicle of 1913 and its predecessors. Shaft drive has made some progress, as distinguished from the use of chains or the combination of means for reducing from motor speed in transmission, in connection with final shaft drive.

Taken as a whole, the past year has been the best ever enjoyed in the industry. The total production of electric passenger cars was not far from 6,000 and the demand generally in excess of production.

For 1913 plans have been laid to make about 10,000 cars, and the orders booked since autumn and still unfilled make such a figure look reasonable. The current orders are fully 10 weeks ahead of several of the factories.

The chief tendency to be noted in the electric passenger car field is toward the centralization of effort upon one chassis type, no matter how many body styles are used. This is the same tendency that has been found in current gasoline practice and is in line with the progressive ideas that permeate the whole structure of American manufacturing.

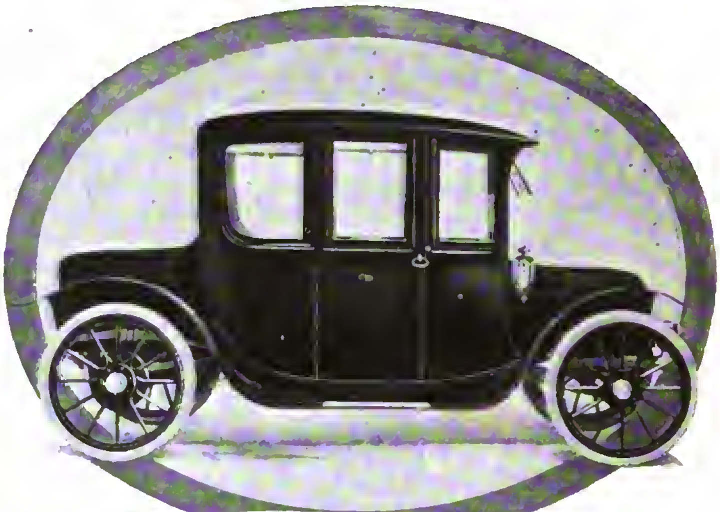
Judging from the changes announced for this year, the most serious fault of electrics generally in the past was lack of power. Last year several of the major manufacturers increased the battery equipment and this year the 40-cell, 11-plate lead battery or the 60 or 64-plate nickel-iron battery have been made standard equipment or first option by the more prominent manufacturers.

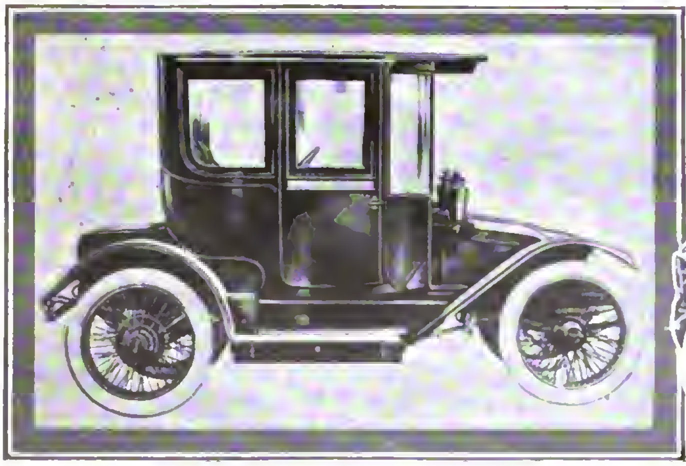
In order to use the extra supply of current due to the enlarged batteries, larger motors have been installed. Several companies have substituted 80-volt motors for the 60-volt ones formerly used. It would be inaccurate to say that the average figure is represented by that difference, but in general the 1913 motors are considerably larger than those of 1912.

Electric passenger vehicles keep pace with the gasoline section of the automobile industry according to announcements made by the various factories as to production.

There are twenty-four companies engaged in manufacturing passenger vehicles this year. In 1912 the output was about 6,000 cars, but this year the factories will make 10,000 or more.

Fully 80 per cent. of the 20,000 passenger electrics now in use are distributed west of the Allegheny Mountains, east of the Rockies and



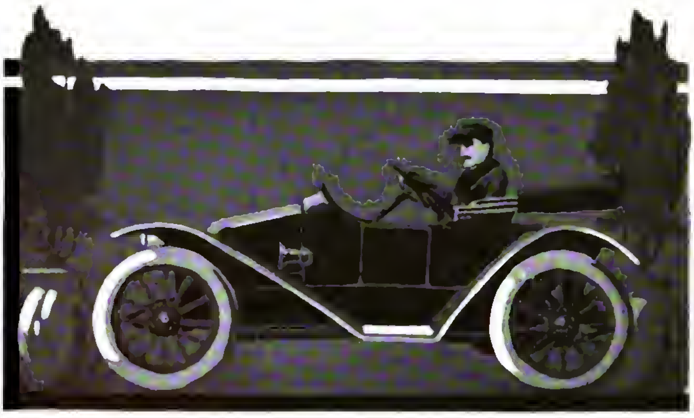


Waverley fore-drive brougham, showing curved lines, model 101, $2,800

Buffalo coupé, model 30, showing wire wheel equipment, price $2,600

Baker brougham, curved roof and graceful body lines, $3,100

Vehicles 1913



north of the Arkansas line. Fifty per cent. of the whole number are in Illinois, Michigan, Ohio and Indiana.

Popular use of the electric is in direct proportion to familiarity with it; therefore the cars have their greatest vogue in and about the cities where they are made.

The chief element in the recent growth of the industry has been the active co-operation of the central stations.

The object of increasing the capacity of the battery and motor is to afford more mileage and the effect may be traced in the largely increased figures in estimated miles per charge. Last year the average claimed mileage was around 70 per charge, with actual performance below that figure due to the difference between general operation on all kinds of pavements and under all sorts of conditions and the expert operation of the skilled driver on smooth pavements. The claims for 1913 range above 75 miles to the charge. Some of the large, prominent companies are chary on mileage claims, and the lower figures on estimated mileage come from concerns that in the past have exceeded advertised figures in real service of their cars.

Deducing from the list of specifications herewith, the 100-mile electric has arrived. That maximum mileage is claimed for certain models by fourteen out of the twenty-four makes tabulated. Naturally, such an extraordinary mileage cannot be delivered under all conditions of road and weather.

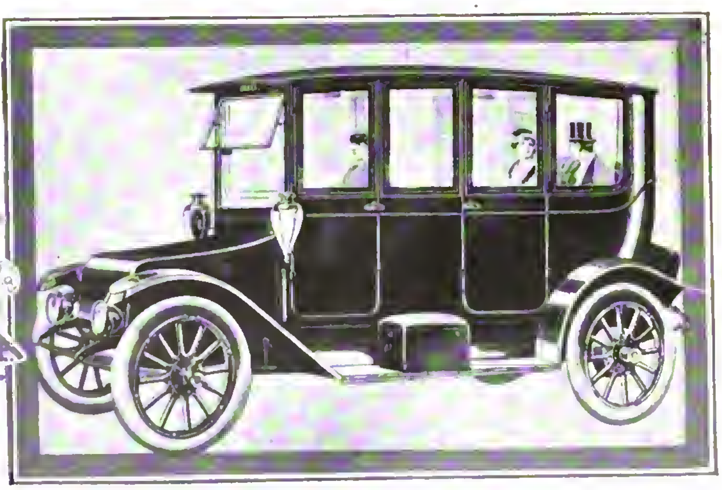
The transmission of power from the motor to the rear road wheels has been the subject of much development work during the year, although actual changes have not been so radical as those that were noted in 1912. Shaft drive has made some progress. Two-thirds of the passenger vehicles are fitted with it, using either the straight-shaft principle or speed reductions between the motor and the propeller shaft. Only two retain chain drive. The final drive in all cases but the two using chains is through bevel spurs or worm gears in the rear axle.

Early in the industry chain drive was used universally and the change to shaft drive or some of its modifications and variations has been accomplished largely within the past 3 years.

During 1912, two companies abandoned silent-chain reduction between motor and propeller shaft to adopt the straight shaft-drive principle. Two more chain-using companies dropped out of competition and those who were added to the industry

Rauch & Lang coach, model J, price $3,100, showing typical construction and graceful appearance given to body design in current practice

Woods, five-passenger, fore-drive brougham, $3,600—one of the characteristic electric passenger types that have been developed during the past year



Detroit limousine equipped with 60-cell Edison battery, $5,000 total reduction between the motor and rear wheels is 11.6 to 1.

The Century is shaft-drive with 4-to-1 bevel-gear reduction in the axle. There is only one universal joint, which is located in rear of the motor.

The Waverley has a characteristic shaft-drive arrangement in that the shaft parallels the rear axle. There is a silent-chain reduction between the motor and propeller shaft of 1.76 to 1, and there is a second reduction in the rear axle by herring-bone gear of 4 to 1. The propeller shaft has two universals.

The Bailey, an example of side chain-drive, transmits from the motor to the jackshaft by chain and from the shaft to the rear wheels by side chains. The reduction between the motor and jackshaft is from twenty-one or twenty-three teeth on the armature sprocket to eighty-seven teeth on the jackshaft. The reduction between the jackshaft sprockets and the rear wheel sprockets is twenty-four teeth to fifty-seven. This gives a total reduction of 9.84 to 1 and 8.99 to 1, the difference in ratio being due to the different number of teeth on the armature sprockets.

Woods uses a shaft drive with double reduction. There is a reduction by herring-bone gear between the motor and propeller shaft and a second reduction in the bevel transmission at the rear axle.

The Rauch & Lang uses shaft drive with double reduction. Reduction No. 1 between the motor and propeller shaft by silent-chain drive is 2 11-28 to 1 and at the rear axle by bevel gear 3 6-13 to 1.

In the Baker chassis the shaft drive is combined with two reductions, the first by silent chain between the motor and propeller shaft and the second by bevel gear in the rear axle. The total reduction amounts to about 10 to 1, but varies in the different models between 9 to 1 and 11 to 1 in connection with a high speed motor, the difference being in the chain reduction.

The Broc uses silent-chain and bevel-gear reduction, the former between the motor and propeller shaft and the latter in the rear axle. These reductions are: silent chain 37 to 21 and bevel pinion 4 to 1.

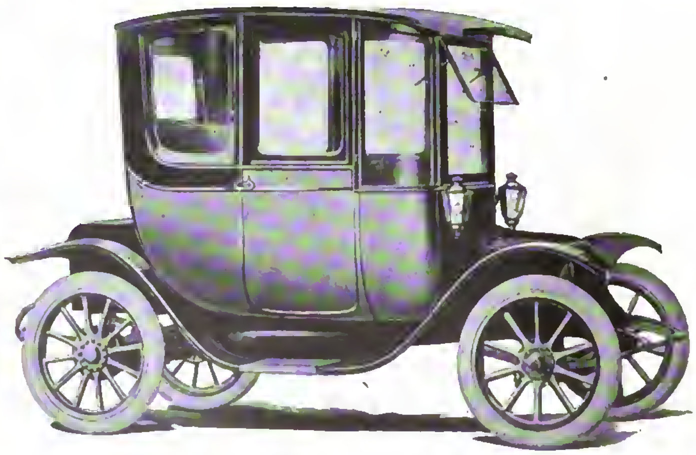
The Standard uses a direct drive without universal joints, and has a double reduction in the rear axle, the first reduction by bevel, the second by spur gears.

It is to be regretted that it is impossible to give the exact methods of reduction, whether double or single employed on one or two of the other cars.

The newcomers this year are the Buffalo, which succeeds the Babcock; the Chicago, Electra and Phipps. Those which have withdrawn are the Babcock, Studebaker, Brunn and several of the small makers. Three of the four new companies use straight shaft drive and those that withdrew used chains either in the regular equipment or as an option.

In the matter of wheelbase there is a decided tendency toward increase. Last year the average wheelbase was a trifle over 90 inches. This has been increased an average of 6 inches,

Fritchle brougham with body designed for family use, $3,600
Grinnell clear-vision brougham, showing long windshield, $2,950
Rauch & Lang brougham, model BB, five-passenger, $2,900
Argo, model A, four-passenger brougham, with curved hood, $2,800



Standard, model M, deep extension and U panel door, $1,885 but the bald statement does not tell the whole truth. By averaging all the 1913 models, the figure appears to be accurate, but it should be less than 96 inches, using the whole production as a basis because the most popular models are not those that are represented by extremely long wheelbases. A more exact figure would be about 94 inches. As a rule, the model upon which the manufacturer has put forth the most effort is the one that most closely approximates the average figure in his line.

The reason for lengthening the wheelbase of the electric passenger vehicle is to provide greater luxury and comfort as well as to provide more space for mechanical developments. This points first to enlargement of bodies and the increased size of passenger compartments in the inclosed cars. In several of the makes, notably Rauch & Lang, Detroit, Waverley, Baker and Woods, some of the bodies are materially larger than they were last year. The drop-frame emphasized in Woods construction lends itself to more room inside and more latitude in seating arrangements.

The additional wheelbase means that nearly all the manufacturers have cars with seating accommodations for five or more passengers, which would have been uncomfortable without the extra inches that have been added.

Despite this general enlargement of bodies, the cars of 1913 do not have a top-heavy appearance. This is due to a certain extent to the lowering of the bodies, but to a much larger extent to the art of the body builder who has striven to do his work in such a way that while the actual additional space is used in length, height and width, the visual impression is not that of increased size. Naturally, in order to be harmonious, some appearance of increase might be expected from the actual increase in chassis length, but that impression is not given by the cars themselves.

The fore-drive idea which developed rather suddenly last year has made some progress in the current models. Almost all the leaders have one or more models embodying this idea.

Colonial coupé bodies, embodying the type of body structure and fittings associated with the term, are continued for 1913 by the companies that introduced them heretofore. The colonial idea in body construction is worked out in a variety of ways in the brougham types. Curved lines in the tops are used more frequently this season. This is the same tendency that has been noted in gasoline automobile bodies of high class, but it is still uncommon.

The roof of the extreme type of the curved-top body is the arc of a circle having a radius of about 50 feet. This type is more frequently used with cars of low suspension.

The elimination of sharp angles in body work is quite a feature. While a few models are equipped with bodies, the exterior outlines of which show no angles, being rounded in the rear, front and sides where the roof joins the sides; with

Chicago brougham model, showing appearance of arched door, $2,800

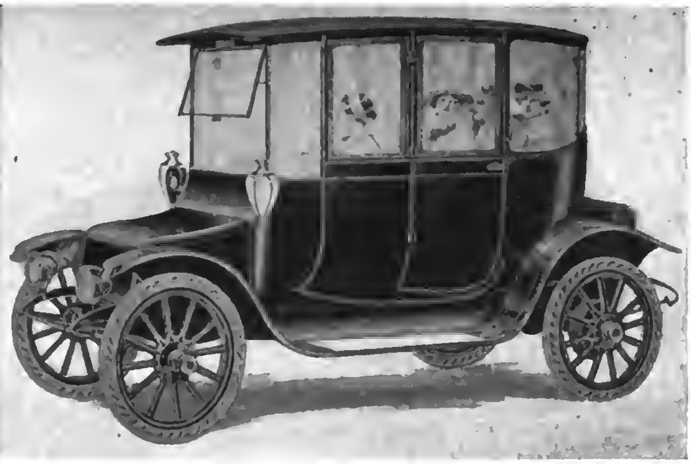
Detroit clear-vision fore-drive model in city and suburban type



Detroit brougham, showing windows in rear corner panels, $3,600

Fritchie roadster, four-passenger, with large battery capacity, $2,500

Bailey victoria-phaeton, similar to 1912 model, $2,600

curved roof and rounded rear, such practice is not to be regarded as representing a standard type. Some one or two elements of the non-angular type are used in a majority of the bodies. Rounded corners at the junction of the rear and side panels is all but universal and the elimination of angles in the lower rear portions is steadily growing in popularity. Upholstery is of neutral-tinted whipcord in the highest-priced cars.

Improvements in the fittings for windows have been made in several important lines of manufacture. These consist of fastenings and frames to check the tendency to rattle and to facilitate raising and lowering.

Open-bodied types of electric passenger vehicles developed only slowly during 1912. The roadster type is continued and the victoria and phaeton are in demand, but the high-pressure business has been done in the inclosed cars.

All over the country the effort has been made to bring out prominently the service of the electric towncar, brougham, coupé and limousine as a supplement to gasoline equipment or as a substitute for it. The immediate effect of this campaign is to be seen in New York, which up to now has been a regrettably poor market for the electric. During 1912 the dealers in the metropolis disposed of about 200 cars, and as nearly as can be estimated half of the sales were to persons already owning gasoline automobiles, or who had owned them in the past. As the electric lends itself readily to feminine handling and is peculiarly available for service in the city, the conclusion is that the women of the family use the electric for town service. This alone is sufficient to warrant the emphasis laid on the inclosed car by the manufacturers and it also accounts for the general lukewarmness toward the open cars.

Equalizing the weight carried by each axle, and in some cases, the apportionment of load to each of the four wheels has occupied some attention by designers and engineers during the past year. The tendency is growing toward equalizing the load between the axles and the division of the battery is more generally made than last year. It used to be considered good practice to place the battery between the axles, but the washing of the electrolyte and the extra strain imposed upon the frame were two definite disadvantages about such arrangements and now the accepted idea is to make each wheel carry an equal load. This is accomplished in various ways to meet the ideas of the engineers.

One of the practical effects of the redistribution of load is to be seen in the improved spring equipment that has been developed within the past 2 years. Another is in the increased mileage delivered by the tires. The tire companies have gradually extended their mileage guarantees under the influence of the intelligent revision of the load. Today several of the tire companies guarantee 10,000 miles for their tires.

In the line of minor improvements every manufacturer has added something to the 1912 models. Broadly speaking, every improvement that has been made is patented. This applies to the signal device installed in the new Rauch & Lang cars to warn the operator when the current still flows after the car has been stopped and the foot brake applied; to the body designs of the Waverley product, as well as other concerns; to the new rain-vision shield and numerous other details. No radical, basic patented devices were developed in 1912. They were all matters of detail.

The subject of tires is one of the most important in motoring generally. Tires for electric pleasure vehicles depend largely upon the locality where used. Solids can be used where vibration is minimized; cushions have a wider field. There is a wide variation between the solid dual-tread tires used on some of the Woods models and the new MacNaul pneumatic furnished with the Rauch & Lang line.

The Motz tire is in general demand. The new tires placed on the market this year are few. The Woods solid is one of them. This tire is made by the Firestone company and is in effect a cushion. The base of the tire is no wider than the standard rim, but it is divided longitudinally around the circumference so that there are two surfaces bearing upon the pavement. This gives something the effect of a non-skid tread. The cushion clincher, made by the same company, is simply a cushion tire made in such form as will fit a clincher rim. The side-wire tire is what its name implies. All are guaranteed for 10,000 miles, limited to 2 years' service. Goodyear, Goodrich, United States, Republic and other companies make electric pneumatics the same as in former years. The MacNaul tire is the most radical development of 1913. This tire is oval in shape and has a tread 7-8 inch thick. It is of the ordinary pneumatic type in some respects, but requires an air pressure of but 50 pounds to the inch to give its best service. The guarantee is for 6,000 miles.

The question of speed enters into the situation this year more than ever before. This is due to the increased possibilities for speed in the 1913 cars. The tire makers have united in limiting the effect of their guarantee to the use of their tires at an outside limit of 20 miles an hour. It has been only a short time since the first electric, equipped with a closed body and not intended specially for racing could make 20 miles an hour, but this year any of the stock cars can touch that rate of speed, and some of them can exceed it.

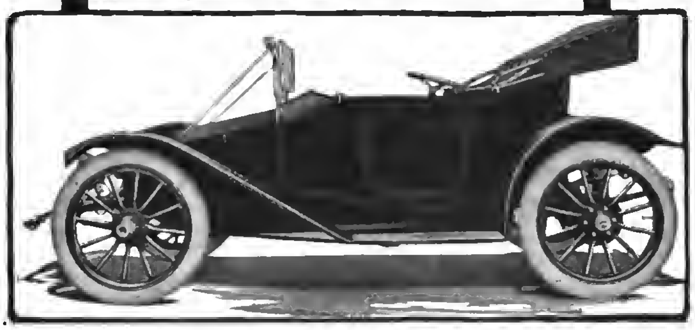
Little change from last year is to be noted in the matter of steering gear. The wheel is used almost exclusively for the outside drive cars, although there are some exceptions. The wheel is also used in some of the fore-drive models, but lever steer is still the prevailing practice in a majority of models. The large companies either make cars with both types of steering gear or will furnish either optionally.

Two changes from magnetic to mechanical brakes appear among the 1913 cars as compared with those of 1912, and one has substituted the magnetic brake for the type formerly used.

The average price of the electric is $2,800. The range extends from under $2,000 to over $5,000. On a strict basis of comparison with the cars of last year, model for model, the 1913 price is higher by about $150 per car. But the story told by averages is incomplete. In 1913 there are fewer cars selling under $2,000 but more at $2,500 or less. At the same time those selling from $3,6co up have increased in number of models. The medium-priced cars are lower in price than last year, but the comparison should not end there. In the same price class as 1912, the 1913 cars offer much more value. They are larger, more powerful and more luxuriously fitted. In other words, where prices have not been slightly reduced, more value is offered for the customer's dollar than before. Thus while the average price for 1913 is higher, it is due more to the elimination of some of the cheaper cars than to a raise all around.

One of the most interesting announcements made this season is that of the Anderson Electric Car Company that its models for the next 3 years will not show any material change from the current offerings. This indicates that in the opinion of one prominent manufacturer at least the present type of electric automobile has a degree of permanence. If this conclusion should prove to be correct and well based the future of the electric will be limited only to its development. If the main principles of the electric are now well-established, the manufacturers can devote more energy to details and to the enlargement of their market.

Following is a brief outline of the various lines of manufacture noting the changes made in comparison with former years:



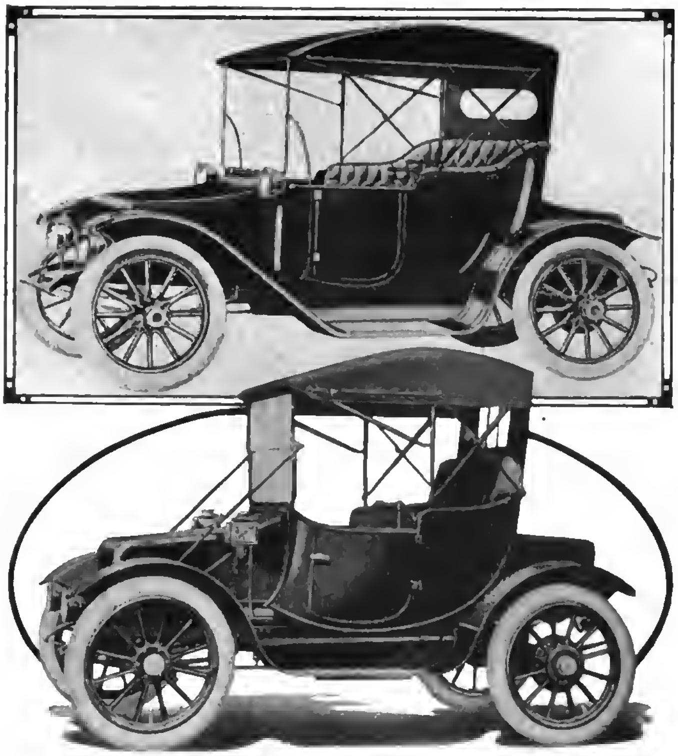
Woods roadster, model 1320, price $2,400
Argo torpedo, which might be taken for gasoline car, $2,500

Argo

Three models are presented for 1913, two of which are new. These are a roadster and a fore-drive limousine. The roadster model has a passenger capacity of four and is equipped with a forty-cell Exide battery designed to give a speed of 25 miles an hour. All the Argo models are shaft driven, using two reductions, the first being by herring-bone gear at 2 to 1, located between the motor and propeller-shaft and the second through bevel gears at 4 to 1 between the propellershaft and the rear wheels. The batteries are 33 1-3 per cent. larger than in 1912 and the estimated mileage of the roadster is given as 100 miles on a single charge, while those of the limousine and brougham are placed at 85 miles. The tire sizes are 38 by 4 and 36 by 4 inches for the front and rear wheels, respectively, and the tire equip-

Ohio, four-passenger car, with only one straight line, $3,200

Columbus, model 1234, illustrating new body type



Detroit roadster, with adjustable top and windshield, $2,350
Rauch & Lang roadster, showing different phase of same idea, $2,600

ment is pneumatic, although certain options are offered. Aside from the increased size of the batteries, the chief changes for 1913 consist of improved support for the motor; detailed refinements in body and fender design and added luxury in upholstery and equipment.

Baker

The Baker line is equipped throughout with bevel-gear, rear axles and shaft drive, using silent-chain reduction from the motor to the countershaft. The line offered includes a victoria, colonial brougham and extension brougham. Two extension coupé types are continued. The extension brougham is fitted with seats all facing forward and is a five-passenger car design for family, social and theater work. It embodies all the established Baker features of sumptuousness and is in the high-price class. The passenger compartment has been enlarged and is now 75 inches from glass to glass. The wheelbase of this model is 107 inches. The car has a battery of forty-two cells. Wheel steer is used on this model. The regular Baker brougham has a wheelbase of 92 inches with the same battery equipment as the longer car. Special emphasis is laid on the completeness of the equipment furnished with these cars, which includes besides the full lighting outfit a set of recording and measuring instruments, tools, flower vase and toilet set.

Bailey

Changes in the Bailey vehicles consist in lengthening the wheelbase of the phaeton model from 81 to 82 inches to give a little more ease to its riding qualities. The long roadster presented last year has not been continued. An option of cushion tires is offered with the phaeton model. Chain drive is retained. Morse silent chains being used to the countershaft and roller chains to the rear-axle sprockets. the reductions being 9.84 to 1 and 8.99 to 1, respectively, for the two chassis.

Borland-Grannis

An outside-drive coupé, equipped with an Exide battery of forty-four cells, with a maximum speed estimated at 25 miles an hour, is the feature of the Borland line. The wheelbase has been lengthened 4 inches to 96 inches in the new models and for the particular model, pneumatic tires are furnished. The cars have six forward speeds, and this model has an estimated mileage of 100 per charge. The three other types offered include a roadster with similar battery equipment; a colonial coupé and brougham with forty-cell batteries. The drive is by shaft with silent-chain reduction. The coupé is equipped with a steering wheel.

Broc

Longer wheelbase in the standard models, improvements in the passenger compartments of the inclosed cars, a forty-cell battery in all the larger cars, and 4-inch drop frames to compensate for the enlargement of the bodies are the chief variants in the 1913 Broc line of manufacture. The open types are fitted on chassis with wheelbase of 84 inches, but the inclosed cars all have a length between the axles of 96 inches. Structurally and mechanically the new models are similar to those that have been established previously by the company. But in the body details there have been a number of changes. The upholstery of the rear seats is 8 1-2 inches deep and the seats are sloped to permit of more luxury in settling against the cushioned backs. Slip pockets in the doors, sliding tool boxes in the rear seat heel board, 24-inch doors, and a system of window fastening designed to prevent rattling are some of the improvements. The fore-drive idea has been developed in some of the models.

Buffalo

The Buffalo is a new name in the list of electric vehicles, but it is in reality the successor of the veteran Babcock. The 1913 line consists of a coupé and roadster on the same chassis. The cars are equipped with Philadelphia batteries of forty-two cells and the estimated extreme speed of the roadster is 35 miles an hour, with 100 miles on a single charge. Of course, it does not mean that the car will go 100 miles at 35 miles an hour on a single charge, but that operated at the most economical rate of speed the maximum mileage will be about that distance. Optional tire equipment is offered with the preference on pneumatics. The drive is by shaft to bevel gears with a single reduction in the rear axle. The gear ratio between the bevel pinion of the shaft and the bevel on the differential is 4 to 1. Universal joints are dispensed with and three-point suspension

Colonial brougham with few right-angles showing in body lines, $2,700

is accomplished by two trunnion joints, one on each side of the motor with a ball-and-socket joint fastened to the middle frame cross-bar. The forward end of the drive is thus allowed to move in any direction.

Chicago

The Chicago electric makes its bow to the public by offering a coupé and limousine equipped with a forty-cell Exide battery. The cars have a seating capacity of five and their mileage is estimated at 100 on a single charge. The maximum speed is placed at 23 miles an hour. The car has five speeds and is equipped with 36-inch cushion tires all around. The shaft-drive principle is followed without intermediate reduction between motor and propeller shaft. Options are given as to the choice of steering, either by wheel or lever. One of the distinctive features of the line is the new arched door designed to prevent the destruction of aigrettes, plumes and dress hats. The curve allows rain to drain off on both sides of the door and eliminates the danger of ruin to dresses by reason of a deluge of water from the top of the door when it is suddenly opened. It is also graceful in appearance. Special stress is laid on the body design, which is stylish and comfortable, and the interior is laid out for the all-

Columbus four-passenger car with adjustable top, front and sides

face-forward type if desired. The controller is from a special design intended to operate with continuous torque and equipped with a magnetic blowout to increase its working efficiency. Much of the usual wiring is rendered unnecessary by reason of the fact that the controller is located directly against the motor. Two universal joints are used with the propellershaft, one just behind the motor and the other immediately in front of the axle. The ratio of reduction provided by the bevels is 5 1-3 to 1. The car is designed by Frederick J. Newman.

Century

A new brougham to carry five passengers is the feature of the current line of Century vehicles. The wheelbase has been extended to 98 inches, allowing more space for body improvements. The battery is a thirty-cell Exide with an ampere-hour capacity of 150. With the improved type of Westinghouse motor the car has a mileage estimated at between 65 and 100 on a single charge. Much latitude is allowed in the selection of wheel sizes and tires to compensate for variation of service conditions in different localities. The Century drive is to bevel gear in the rear axle with universal joint behind the motor and bevel-gear reduction at 4 to 1. The car has six forward speeds. Changes from 1912 construction are really refinements and developments rather than anything radical. Lever steer is used.

Church-Field

Another comparative newcomer is the Church-Field company. The 1913 line consists of two models, a roadster and a colonial coupé. The structural feature lies in the two-speed gearset, which serves to give ten speeds forward in place of the usual five. The car is the only one before the American public thus equipped. The shifting is done mechanically through the controlling lever without adding materially to the complexity of that device. The torpedo roadster has a steering wheel. The drive is by shaft. Reduction ratios are 4 and 8 to 1.

Columbus

Five new models are presented by the Columbus company. The main changes are enlargement of the batteries all around, the stanhope having thirty-two cells of Exide battery against thirty cells last year, while the heavier types have forty cells in place of thirty-six. The drive is by shaft with first reduction by silent chain and the second by bevel gear, the total reduction ratio being 11.6 to 1. Lever steering gear is used on the inside-drive cars. The theater coupé is the feature of the line. This is a four-passenger car, heavily batteried with speed ranging from 7 to 22 miles an hour and a range of from 60 to 100 miles on a charge. The seats are arranged so that all may face forward, although one of the front seats revolves at pleasure. Safety of operation is enhanced by the new brake equipment which consists of four internal expanding brakes on the rear wheels and one contracting brake on the driving shaft. The rear tires on this model are 34 by 4 1-2 inches. Otherwise the tire sizes for all models are 34 by 4 inches.

Colonial

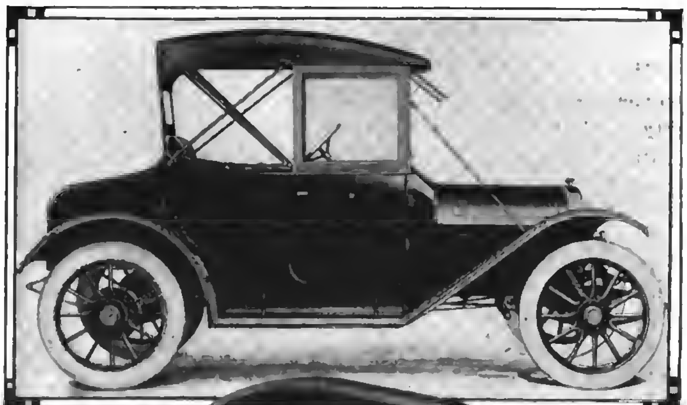
A standard four-pasenger coupé, 96-inch wheelbase and equipped with a Willard battery of forty cells, are the features of the Colonial. A particularly graceful body design is used, the lines being unusually pleasing. The mechanical features of the car are much the same as in former practice with final drive through bevel gear. The charge mileage is estimated at 70. The car has the conventional six-speed controller.

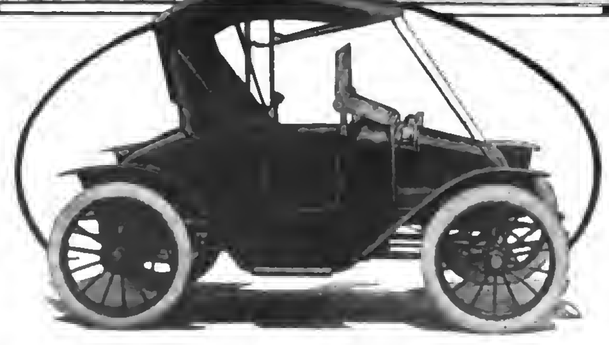
Dayton

The new model of the Dayton line is an extension coupé equipped with a thirty-cell Exide battery giving a maximum speed of 22 miles an hour. The operating mileage on a single charge is estimated at from 75 to 90. The chief improvement in the mechanical sense is the automatic cut-out in connection with the emergency brake, designed for the purpose of preventing fires or overheating of the motor when the car is not in motion. When the brake pedal is pressed down the current supply is disconnected from the motor. The car is shaft driven. It has a passenger capacity of four and the interior of the body is arranged in several styles to meet a variety of demands.

Detroit

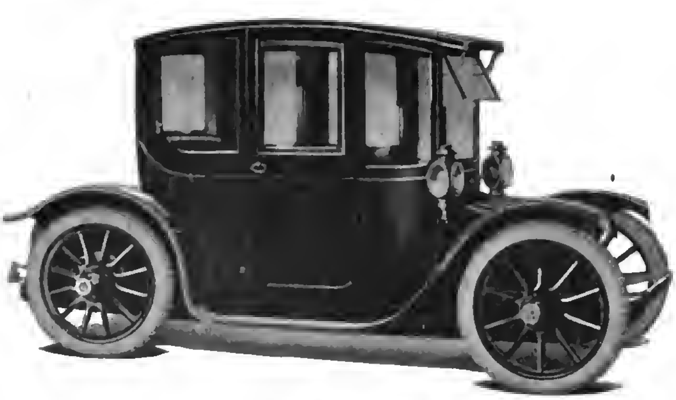
Additional battery equipment, larger wheels on some of the models, a clear-vision car and refinements of details are all the

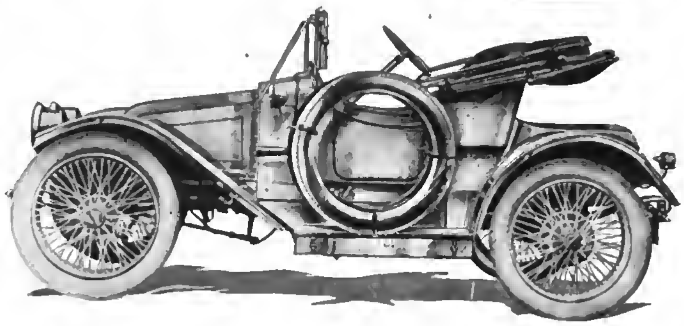




Waverley protected roadster, showing method of enclosing, $2,250
Fritchie torpedo, with battery box in rear, low and rounded, $2,400

changes made by the Anderson company, in fact, the company has announced in definite terms that for the next 2 or 3 years the changes would probably be of minor character. The batteries for 1913 are Detroit electric lead batteries of forty cells, or Edison batteries of sixty-four cells of the A-4 size. The exception is the limousine, which has a sixty-cell Edison of A-6 size. The limousine is steered with a wheel, while the stock equipment of the other models is lever steer. As compared with the 1912, the Detroit cars have two more cells of lead battery or four additional cells of Edison. The mileage figures are increased by reason of the addition. The direct shaft drive adopted by the company, using a universal joint behind the motor and geared in the rear axle at a reduction of 5 to 1, is continued throughout the line. The clear-vision car, which is being featured this year has glass panels in the rear corners of the body. This gives the driver a chance to watch traffic and avoid accidents with more facility than if some opaque substance were used. One of the new details in body construction is the substitution of aluminum for wood in the roofs of the closed cars. Several of the cars are equipped with seats all facing forward. Another change that will be noted is the abandonment of the type of hood formerly used in the roadster. In 1912 this hood gave the impression of a gasoline car, but for 1913 the graceful lines of the hood could not be mistaken for those of a gasoline automobile.





Century brougham, a typical car of 1913 in body design, $2,550
Buffalo wire-wheeled roadster equipped like gasoline car, $2,600

Electra

The feature of this new line is a torpedo roadster with a 90-inch wheelbase and equipped with a Haschke twenty-cell battery. All the usual battery options are allowed at the various prices charged for them. The car simulates a small gasoline roadster very closely in appearance. Shaft drive without intermediate reduction between motor and propeller shaft is used. The rear axle is worm driven. Control lever is located under the steering wheel, which is on the left side of the car. Pneumatic tires are favored, but the usual options are given. The company also lists a larger car with a 96-inch wheelbase.

Flanders

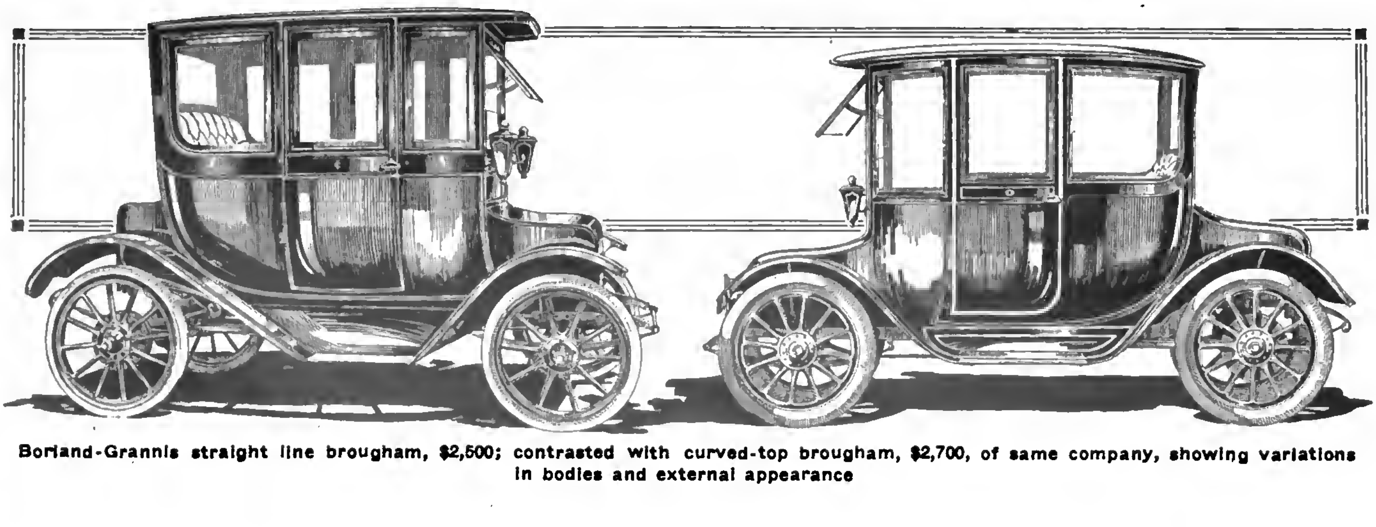
A single chassis fitted with victoria or colonial bodies is the Flanders line. The coupé is the featured car and this year it has a passenger capacity for five persons. The main changes are in the size of the battery, which is a thirty-cell Flanders as against a twenty-four cell-battery in 1912; the Timmerman motor, which had not been definitely adopted last year, and the rearrangement of the seats. The worm-gear drive is continued, as well as the other typical features of the mechanism. With the additional battery capacity, the car is now rated at 20 miles an hour and has a range of travel of from 75 to 100 miles on a single charge.

Fritchle

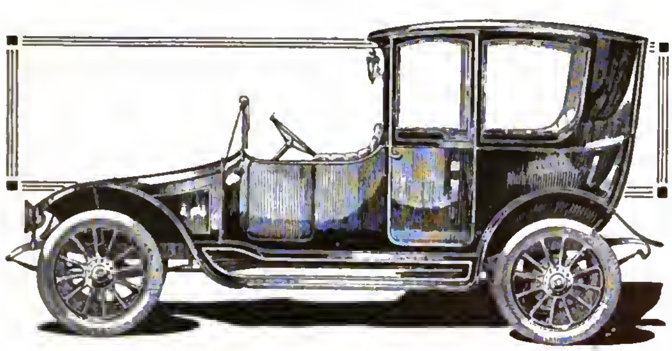
Besides adding a luxurious brougham, dropping its touring car and increasing the battery capacity of two models, the Fritchle vehicle is similar to its 1912 line. The new brougham has capacity for five passengers. The operator's seat is to the left and within the passenger compartment. The opposite seat faces the rear. The back seat is wide enough for three adults. The car is compactly built, the wheelbase of the brougham being only 86 inches. The motors are rated at 4 horsepower and are driven by Fritchle batteries of thirty-two cells. The Fritchle construction, embodying reach-rods between the axles, lends itself to the elliptic type of springs all around, which are used. Wooden sills are used in the frame with the idea of imparting flexibility and to avoid the chance of acid corrosion. These things are not new so far as the Fritchle is concerned, but they differ in some respects from ordinary practice. The drive is by shaft. The brakes act directly on the rear hubs.

Grinnell

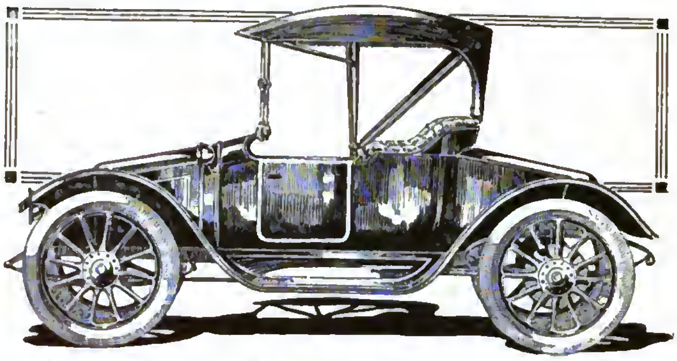
An all-forward drive, clear-vision brougham and a five-passenger coupé are the new things brought out by Grinnell. Structurally the cars are somewhat different from previous models. The shaft-drive principle, using two universal joints between the motor and rear axle, the reduction ratio being 4 1-4 to 1 through bevel gears has been adopted. The braking system has been changed slightly so that the new cars have



Borland-Grannis straight line brougham, $2,500; contrasted with curved-top brougham, $2,700, of same company, showing variations in bodies and external appearance



Luxurious limousine put out by Borland-Grannis—note unique design, $5,500



Roadster of same company—curved lines predominate in body and mudguards

service brakes operated with the controller by hand and the emergency brakes are pedal-operated and work by internal expansion to the hubs. A thirty-cell battery, optional in type, is furnished. This is a trifle larger than formerly and the company estimates that a maximum of 125 miles can be delivered by a single charge. The normal motor speed is 900 revolutions per minute.

Ohio

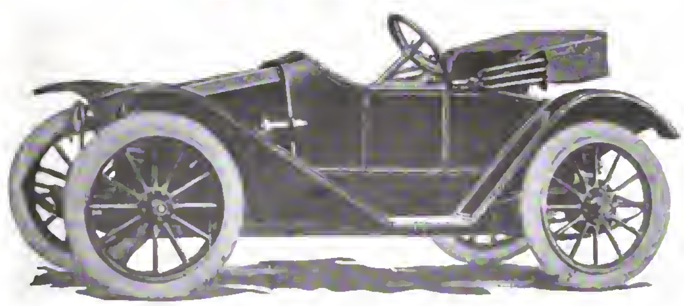
Centralizing effort upon a single chassis type, this company has announced four new models, differing from one another only in the style of bodies. Battery capacity has been increased; the wheelbase of all models is lengthened to 96 inches. The 102-inch coupé has been discontinued; the chain reduction between motor and propeller shaft formerly used has been eliminated and the drive is direct shaft; Crocker-Wheeler motors delivering 800 revolutions per minute at 75 volts, 30 amperes, have been installed in place of the former equipment, and a magnetic brake operated by button-actuated switch has been installed. No universal joints are used in the drive. The armature of the motor is a hollow sleeve mounted on annular bearings. The propeller shaft passes through this sleeve and engages the forward part by a squared end. The shaft itself is short and the ratio between the beveled pinion and the bevel in the differential is 4 to 1. The motor is now attached directly to the end of the shaft. The size of the batteries has been raised from thirty or thirty-two cells to forty cells. This has led to a revision of the mileage figures as 100 miles is now estimated for a single charge. The new body styles include a colonial brougham, straight-line brougham and semi-colonial in two variations. The control of all cars is magnetic and is accomplished by the turning of a disk. Steer is by lever. An electric heater, operated by button switch, is a new feature of the regular equipment.

Phipps

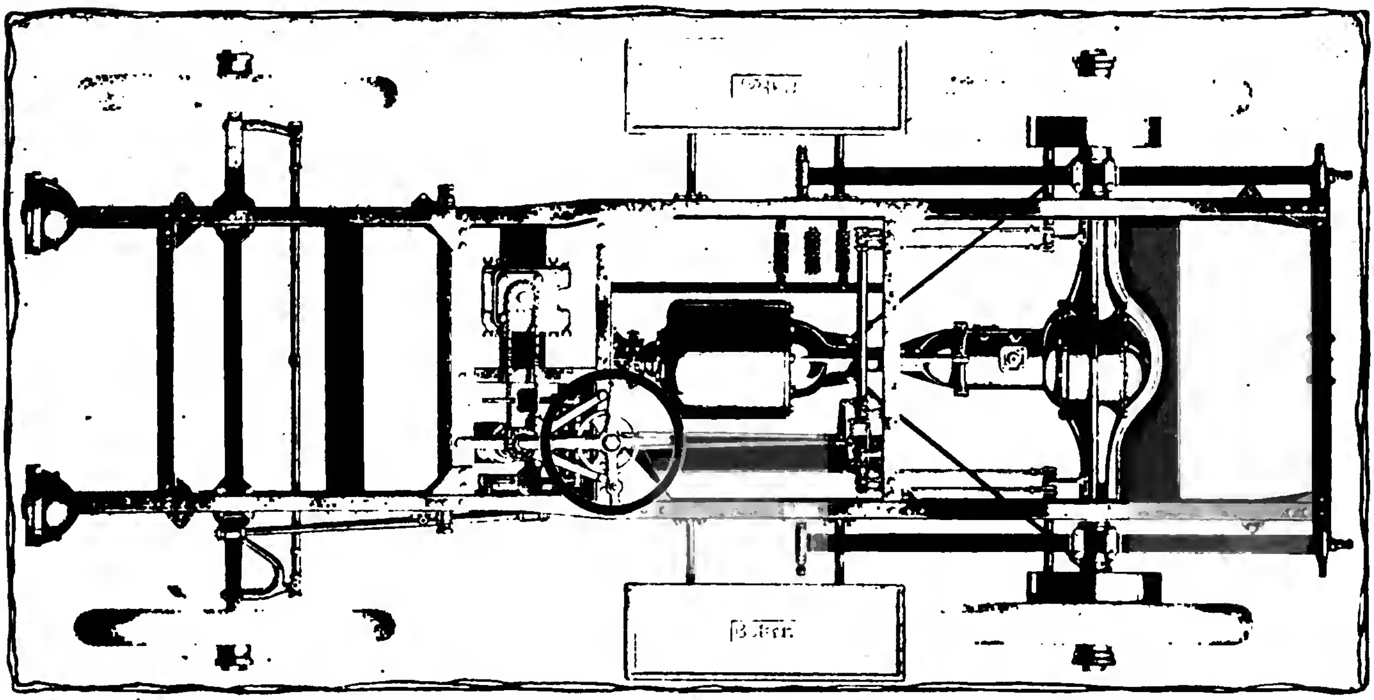
A coupé, equipped with a forty-cell Exide battery, on a chassis with a wheelbase of 107 inches and fitted with wheels to take any standard type of tires 36 by 4 inches all around, is the initial offering of the Phipps company. The motor is of Westinghouse manufacture. The drive is by bevel gear. The car has a seating capacity of five adults. The control gives five forward speeds.

Rauch & Lang

The standard battery for the Rauch & Lang vehicles consists of forty cells, Exide, although sixty cells of Edison A-4 or A-6 and Ironclad are furnished at higher prices. Last year some of the smaller cars had only twenty-four cells. The changes for the coming season are rather numerous. Whereas last year seventeen models were announced, many of them being only variations in body types, this year but seven models are listed. The chief changes consist of the following: The wheelbase of six models has been lengthened 1 1-2 inches to 92 1-2 inches, and in the largest of the broughams the wheelbase is 103 inches; all bodies are lower hung, and the size of the compartment in all inclosed cars has been increased; wide option is allowed in selecting the size of wheels and tires. The size of the brake drums has been increased. The controller is now equipped with a device to prevent accidental burning of the mechanism when not in service. An automatic bell signal sounds when the foot brake is set if the current is still connected with the motor. Disconnection of the current is provided in the controller and the whole device is so arranged that the operator may know that the current is not running if the bell is silent. On the other hand, if the bell rings, it is to show that a small trigger in the controller should be set, disconnecting the batteries. The Hertner motor is used on all models and with the augmented batteries the mileage is now estimated at from 60 to 90. The maximum speed of the Rauch & Lang cars is placed at 20 miles an hour. One other feature of the bodies that will attract attention is the special type of auxiliary rain-vision shield with which the cars are equipped. This consists of a plate of glass placed at an angle to the front of the car just under the roof sill and held by appropriate adjustable frames. The shield extends sufficiently from the front window of the car to protect the glass from rain and conse-



Woods brougham—a roomy car designed for theater service—$3,100
Church-Field roadster which follows lines of gasoline models, $2,300



Looking down on the Baker stripped chassis, showing structural details and mechanical principles of the car

quently affords the operator a clearer view of the road than he would have without such protection. The complete line consists of four broughams, including a demi-brougham and a colonial; towncar, coach and roadster. Several variations of bodies are furnished, chief among which are a landaulet, chauffeur-driven towncar, club roadster and some others. Shaft drive with silent-chain reduction is retained throughout the line. The ratio of reduction by silent chain is 2 11-28 to 1 and that at the rear axle 3 6-13 to 1.

Standard

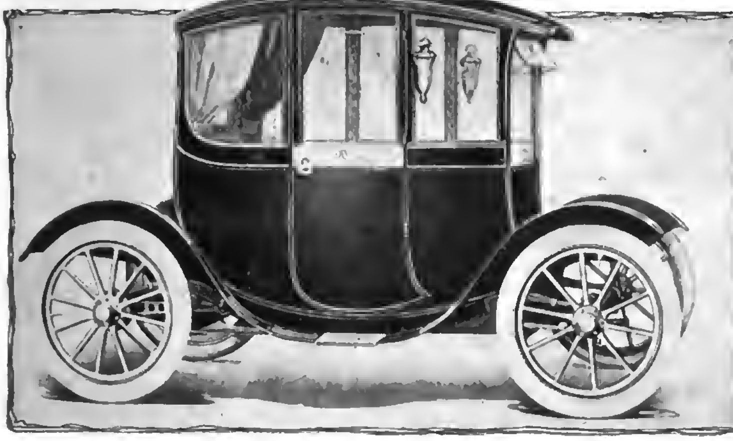
The coupé model of this company is considerably changed from last year's offering. The wheelbase is 5 inches longer and the passenger compartment has been enlarged 4 inches in width and 3 inches in height. The seating scheme has been rearranged so that the occupant of the front seat can sit at an angle of 45 degrees, facing the opposite rear corner, instead of sitting with his or her back to the front of the car. A divided, clear-vision windshield and a ventilator over the front window have been added. The springs have been lengthened 10 inches. The wheelbase is 96 inches. The drive is by shaft without universal joints. Double reduction gears are built into the rear axle. The battery equipment is a thirty-cell Exide, with options at higher prices.

Waverley

Four new models, one materially changed style and the continuation of one model with minor changes are announced by the Waverley company. The new cars are a limousine, Georgian brougham, Empire brougham and colonial brougham. The model that has been sharply changed is the limousine that was featured last year and the one in which minor changes have been made is the sheltered roadster. Generally it may be said that the most noticeable change in all the models is the greater-capacity batteries furnished. Last year the standard cars had thirty-two cells Exide with thirty-four cells in the limousine. This year the standard is forty cells Exide with thirty-four cells in the roadster and optional equipment of Edison or other types of batteries at appropriate increases in price. Eighty-volt motors have been installed in all the heavier cars. The transverse shaft drive, first reduction being in the ratio of 1.76 to 1 and the bevel ratio being 4 to 1, unique in this make, is retained, as are all the essential features of 1912. The new limousine has a divided rear seat, making three spaces, with the middle space or seat slightly in rear of the other two. The car is driven from the left rear seat, while a cozy-corner seat in the right front corner does not interfere with the operator's view ahead. This car has a wheelbase of 106 inches and an estimated range of 75 miles on a charge. The Georgian brougham is 3 inches longer,

Broc stanhope model 20, price $2,100; also in victoria

Broc fore-drive brougham, model 31, price $3,500



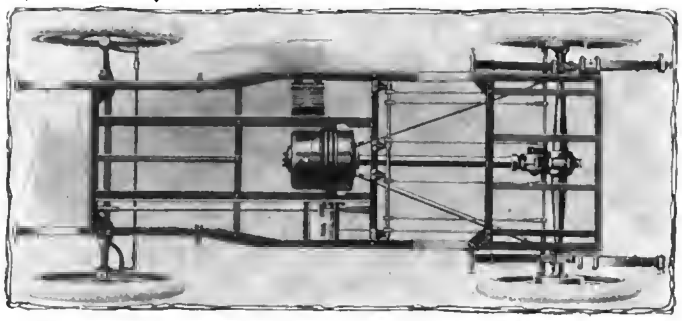
Flanders colonial coupé, listed at $2,500

Broc curved top brougham, model 29, price $3,100

but otherwise structurally the same as the limousine. The passenger compartment is arranged so that the person who sits in front of the driver sits with his or her back to the side of the car. The rear battery box is separate from the body. The Empire brougham has the same seating arrangements as the foregoing, but the wheelbase is 106 inches and the battery box behind is connected with the body. The colonial brougham is 2 inches shorter than the Empire and is equipped with the typical characteristics of the colonial style of coach building. The five-passenger limousine continued from 1912 has 5 inches more wheelbase, 5 inches wider rear seat, lower sill, larger battery, bigger motor and semi-irreversible steering mechanism. Several of the former models that proved popular are continued without radical change. Lever steer, wooden trussed frames, I-beam front axles and the other established features of the Waverley product are continued.

Woods

Elimination of weight, drop frames, giving lower suspension of bodies, more graceful lines, heavier and larger batteries with a meter on the charging plug, two-point motor suspension, reinforced rear axle having radius rods to the torsion tube, and a system of fastening the batteries in place are the improvements announced for the Woods line. The shaft drive with herringbone gear reduction and other structural and mechanical features are retained. The standard Woods battery is forty-cell Exide, but in the 102-inch brougham a Woods battery of forty-two cells is installed. Dual-tread solid tires of a different type than any used before on an electric passenger car are stock equipment for several of the models, although other options are offered. The motor and mechanical changes are designed to give easy riding qualities and greater mileage

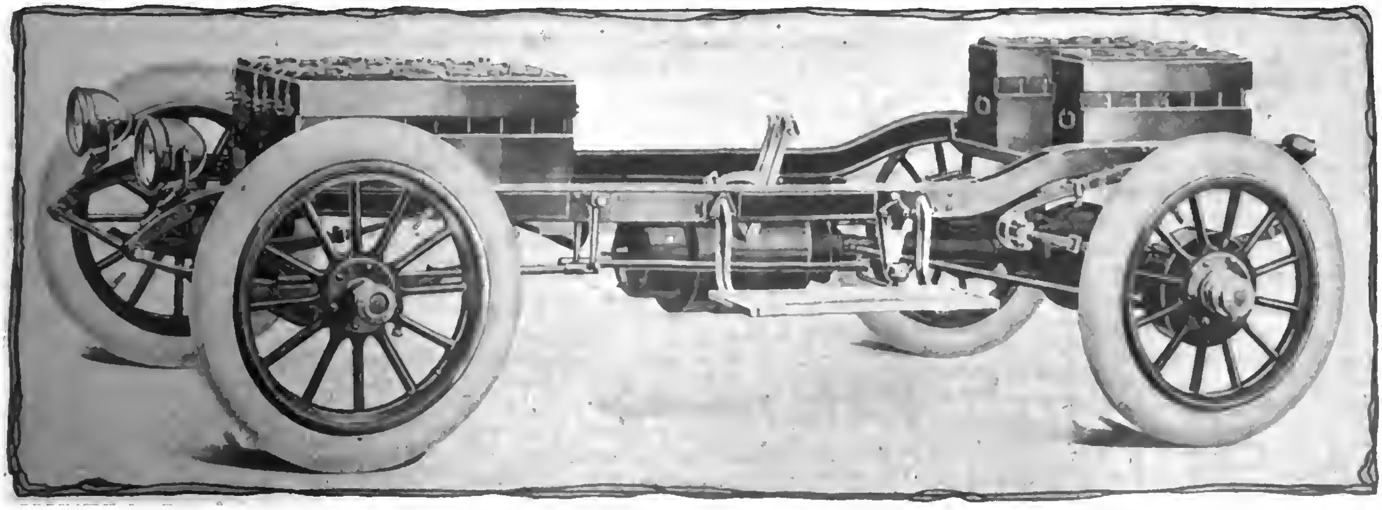


Looking down upon chassis of Standard, showing mechanical details

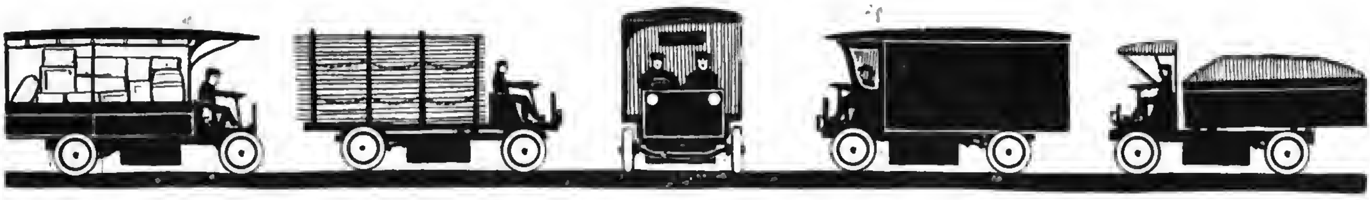
through the elimination of vibration. The two-point suspension and the bracing of the torsion tube by radius rods are all part of the plan to further adapt shaft drive to solid or cushion-tire equipment, which has been worked out with so much success by this company.

Hupp-Yeats

The Regent model is the special element of this line emphasized this year. This is a coupé similar in every way to the foregoing model of the same type. It has a twenty-seven cell Exide battery, ranged in three trays. The motor is located upon the rear axle, driving by bevel-spur gear at a reduction of 4 to 1. The car is very low slung but the frame has a rise of 9 inches at the rear. The interior of the car is roomy and lends itself to a rather wide latitude in the matter of seating arrangements, despite the fact that the wheelbase is only 86 inches. The motor is of Westinghouse design. The rear axle is of the semi-floating type. Lever steer is regular equipment. The car seats four.



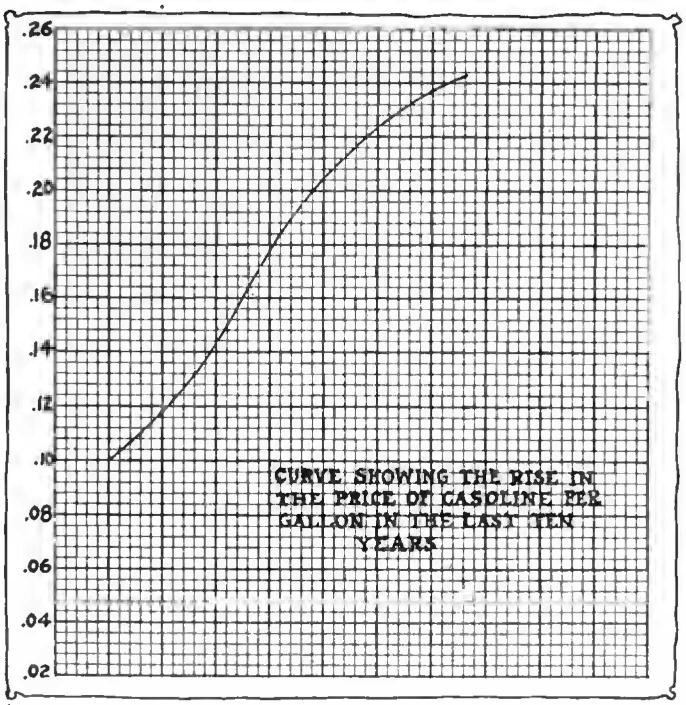
Detroit chassis, showing division of battery and structural particulars of frame, suspension, motor and drive



The Electric Commercial Vehicle

Two-Thirds of Those in Use at Present Are of 2 to 3-Ton Type
Field Is Rapidly Enlarging and Future of Industry Is Bright

STATISTICIANS estimate that about two-thirds of the electric trucks in use at the present time are of the 2 to 3-ton size. The past year has seen many new concerns which have never owned or operated electric vehicles buying one or two trucks, endeavoring to find out which is the best suited for their business, before installing a large fleet. The forecast for this season's models does not show any radical departure from present practice. Minor improvements or changes will be made from lessons learned. One of the pronounced trends is to increase the types of vehicles manufactured by building one or more heavier models. Included in this class are such concerns as the Baker that has added a new model, Type C C, with a carrying capacity of 7,000 pounds; Detroit, Model 7, 7,000 pounds; Ward, with an entire new line, including a 2 and 4-ton chassis in addition to smaller ones; Waverley, with three new chassis of 4,000, 7,000 and 10,000 pounds capacity; and the Victor, which purposes giving up smaller vehicles and confining itself to the 3.5 and 5-ton chassis. The Atlantic Vehicle Company, which offered its product to the public about the middle of last year, also caters to the heavy class with 3.5 and 5-ton trucks, and, being a newcomer, the line that it offers is somewhat indicative of the general demand.



Silent chain of the inverted tooth type is very popular as a method of transmitting the power from the motor to the differential, where final chain drive is used, offering as it does a certain degree of flexibility of drive coupled with silence, while its efficiency is materially enhanced by protecting it from foreign matter by inclosing it in an oil-tight and dust-proof casing. Among the concerns that use this method of drive are Detroit, Baker, General Vehicle, Urban, Ward and Atlantic.

As a contrast to this type there is the Lansden company, which couples the motor direct to the differential, an extension of the differential casing being bolted direct to the motor housing, with chains as a final drive.

Other concerns such as the G. M. C. and the Waverley, in their new models, interpose a shaft between the motor and the countershaft, thereby locating the motor over the rear axle and driving forward. M. & P. reverse this method by placing the motor forward under the seat and transmitting to the differential through a universal-jointed shaft.

Left-hand steering, adopted several years ago, remains as standard. Some concerns have given a slight rake to the steering column, but there is no marked departure from last year's practice.

The wooden or metal-lined battery cradle is giving way to the

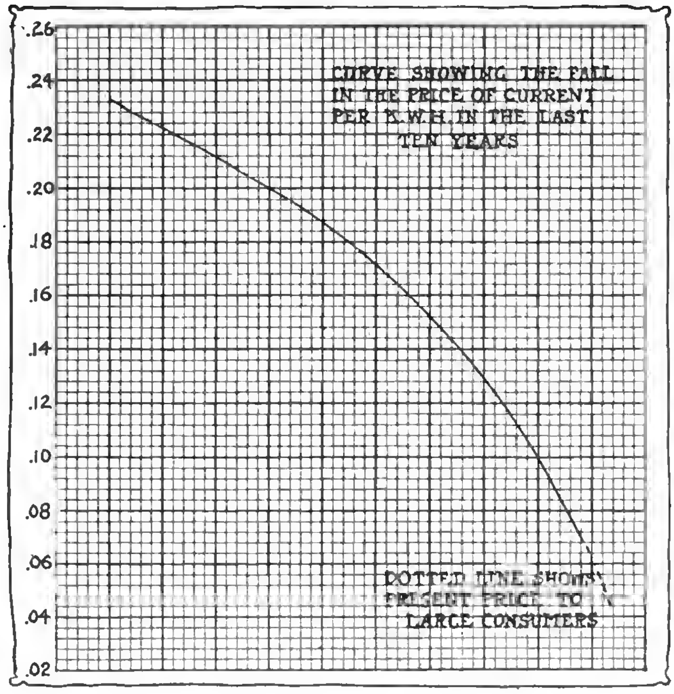
Tendencies and Constructional Details

Many Companies Are Adding Heavier Machines to Their 1913 Lines Considerable Progress Made in Battery Equipment Standardization

all-steel construction. Some manufacturers, such as the Lansden and Detroit, hinge the sides at the bottom so that when they are swung open they form, with the aid of supports, a tray upon which the battery can be withdrawn to afford inspection, leaving the top hermetically sealed, thus excluding all foreign matter. To facilitate the withdrawal in some cases the battery is made to slide on rollers in grooves.

Battery equipment has become considerably more standardized during the last year, and the new models show a tendency towards 42 or 44 cells lead type, or 60 cells Edison. The number of plates per cell depends upon the vehicle capacity. With perhaps the exception of the G. M. C. and the Champion, practice is to suspend the battery below the frame forward of the center.



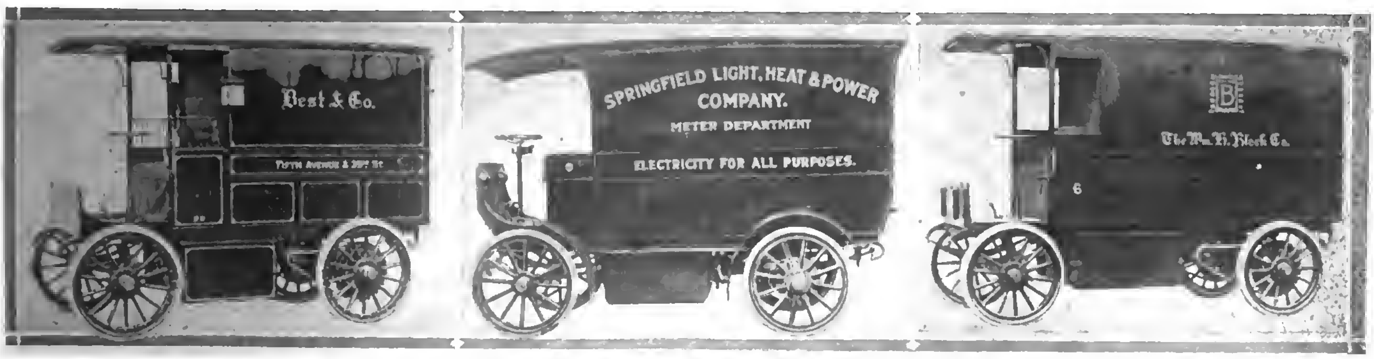
One of the greatest points in favor of the electric is that it is self-governing as to speed. The maximum speed cannot be exceeded unless the driver deliberately permits the power to add to momentum when going down hill. As there are no gears to mesh, the power should be cut off and the vehicle allowed to coast at a moderate speed, thereby saving current. If this is done the mileage radius of the battery will be so much more increased if only the driver would ease off the power when he sees that he must make a stop several feet ahead. Some drivers have a bad habit of keeping their feet constantly upon the brake pedal, bringing the shoes in constant contact with the brake drums and thus throwing additional work upon the motor and unnecessarily consuming current.

The following is a table compiled by averaging the speeds as given by several of the principal makers in their instructions, with a table compiled by Alexander Churchward.

Load Capacity in Pounds	Maximum Speed in Miles Per Hour	Mr. Churchward's Table, Miles Per Hour
500	16-20	.. ..
1,000	13	12 to 13
2,000	11	10 to 11
3,000	10	10
4,000	9	8 to 9
7,000	8	7 to 8
8,000	7	6.5 to 7.5
10,000	5.5	6 to 7

Each maker has his own idea of the speed at which his vehicle should travel, and while it might be perfectly safe for one truck to be driven at 10 miles per hour without any harm, another with different suspension would suffer materially from the results of excessive vibration.

It stands to reason that the same speed cannot be attained with a full load as when the vehicle is running empty, consequently it behooves the person in charge to see that the driver does not take advantage of this fact and make fast time in returning from deliveries. More harm is accomplished in driv-



Left—General Vehicle of 1,000-pound type. Center—1,000-pound Argo with distinctive body. Right—2,000-pound General Vehicle ing an electric truck fast without a load than when it is driven to the maximum with a load. The load relieves the frame of part of the vibrations, and although solid rubber tires are capable of absorbing part of the road shocks, nevertheless a major portion is transmitted throughout the entire vehicle.

There has been a healthy impetus given to the electric vehicle business in general through the whole-hearted co-operation of the various central stations and electric power companies throughout the country. These companies not only set the good example by using electric vehicles themselves, but also offer attractive rates to current consumers, and in some cases are catering to the charging of electric trucks in special garages erected for the purpose.

The rate for charging current has dropped in the last few years and some stations have notified their intention of still further reducing the cost to both small and large consumers. Reference to the curves on pages 24 and 25, will make it apparent that the cost of electrical current has dropped in almost direct proportion to the rise in the price of gasoline. The cost of current worked against the electric in the early days, but now this objection has been removed.

The present efficiency of the electric is in no small measure due to the general advances that have been made in automobile construction, tending to simplicity and comparative lightness of design, thus rendering this type of vehicle more efficient in the few working parts that it possesses.

The standard tire and wheel dimensions for solid tires as recommended by the Society of Automobile Engineers have been generally adopted by the makers, and this has brought about a much better state of affairs, cutting down the idle time caused by tire replacements.

The average wheelbase of all models of electric trucks has

Note.—*Price with lead battery; Opt., Optional loading space.

increased several inches, with the exception of the 2-ton chassis, which remains about the same. The following table gives the average wheelbases for the various sizes of trucks for 1912 and 1913:

Carrying Capacity, Pounds	Average 1912 Wheelbase, Inches	Average 1913 Wheelbase, Inches
1,000	85	90
2,000	93	100
4,000	118	117
7,000	125	130
10,000	132	140

In the compilation of this table the standard wheelbases have been taken as the basis of the calculations, but in special designs built to order the standard is not always adhered to.

There is at present some lack of standard as to the type of lamp, and at the recent meeting of the Electric Vehicle Association it was proposed to adopt the Edison bayonet-type of fitting in preference to the screw type. A consensus of opinion among those present at the meeting was in favor of the bayonet type.

The following table has been compiled from statistics obtained by THE AUTOMOBILE, and shows the number of manufacturers engaged in the manufacture of vehicles of various capacities:

Capacity, Pounds	Number of Manufacturers	Capacity, Pounds	Number of Manufacturers
500 pounds	4	5,000 pounds	1
1,000 pounds	13	6,000 pounds	1
2,000 pounds	13	7,000 pounds	8
3,000 pounds	2	8,000 pounds	1
4,000 pounds	8	10,000 pounds	6

The following is a brief resumé of the general features of the different electric commercial vehicles offered by the various makers for the coming year. Such points as battery equipment and suspension, control, motor location and method of drive have been handled. In addition to these items more specific information concerning weights, prices and other useful information is contained in the detailed tabulation given herewith.

ABBREVIATIONS.—Opt. either lead or Edison battery; Comp, compound-wound generator; ½ Ell. semi-elliptic springs; Ell, elliptic springs; ¾ Ell, three-quarter elliptic springs; Bevel, shaft drive with bevel gear reduction; Worm, shaft drive with worm gear reduction; Spur, direct drive from armature shaft through spur gear in wheel.

The following brief reviews of the various makes of electric commercial cars will serve to indicate the progress made by each during the past year as well as to give an idea of each company's line for the season of 1913:

Argo

¶ These vehicles are made in two models, namely, 1,000 and 2,000 pounds. The battery equipment for both is forty cells M. V. Exide with eleven plates each for one and thirteen plates for the other. Four speeds are provided in both cases, giving a graduation of 2, 4, 8 and 12 miles per hour. The battery box is suspended from the main frame by a subframe with side doors. A separate door in the truck platform is provided above the battery to facilitate flushing. No material change has been contemplated for the ensuing year either as to battery location or on any mechanical points. Final drive is by bevel gear, the motor being coupled to the rear axle, forming a single unit. The armature shaft runs parallel with the side members of the chassis and is slightly up-tilted at the forward end, where it is attached to a cross-member of the frame. A feature of these trucks lies in the rear suspension; the semi-elliptic springs are attached to the rear axle in the ordinary way, but the distance between the springs is less than the width of the chassis, owing to the shackle brackets being attached slightly inboard. The available loading space of the smaller model is 7 feet 6 inches, while the larger model is 10 inches longer for the same width. The overall length of the K10 type is 129.5 inches, extreme width 68 inches, and can be turned in a circle 40 feet in diameter. The smaller type is 10 inches longer overall than the other, this being accounted for by the extra loading space, with the same width, namely, 68 inches, and can be turned in a 48-foot circle.

Atlantic

¶ Atlantic trucks are made in four sizes with a carrying capacity of 1, 2, 3.5 and 5 tons, respectively. This company started to manufacture last March. The four chassis are similar in design and only such necessary variations have been made, taking into consideration the difference in weight and loading capacity. No radical feature of design is incorporated.

The batteries, composed in all models of forty-four cells of the Hycap Exide make or sixty cells of the Edison type, are carried in cradles suspended beneath the frame, permitting of loading and unloading from either side. The controller is situated beneath the driver's seat, the operating lever being placed within easy reach of his left hand. The accessibility thus obtained renders inspection and renewal at any time a very simple matter, the current from the battery being fed through well-insulated wires of liberal carrying capacity. Four forward and two reverse speeds are provided. The motor is suspended from a frame cross-member back of the jackshafts, which are situated amidships, the final drive being effected from the sprockets on the jackshafts to the rear wheel hubs by means of roller chains. The motor shaft, which runs on ball bearings, is fitted with a sprocket, and the power is transmitted to the differential sprocket by an inclosed Morse silent chain. Particular attention has been paid to the suspension of the vehicles, imported silico manganese being used for the springs, which are of the semi-elliptic type and are composed of a comparatively large number of thin, highly-tempered leaves. Two independent brakes are provided, the service brake of the expanding type operating on the rear wheel drums and the emergency brake of the contracting type fitted to the center of the countershaft. Both are pedal operated.

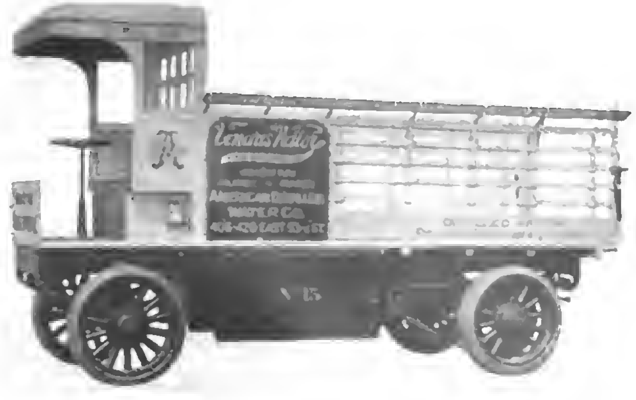
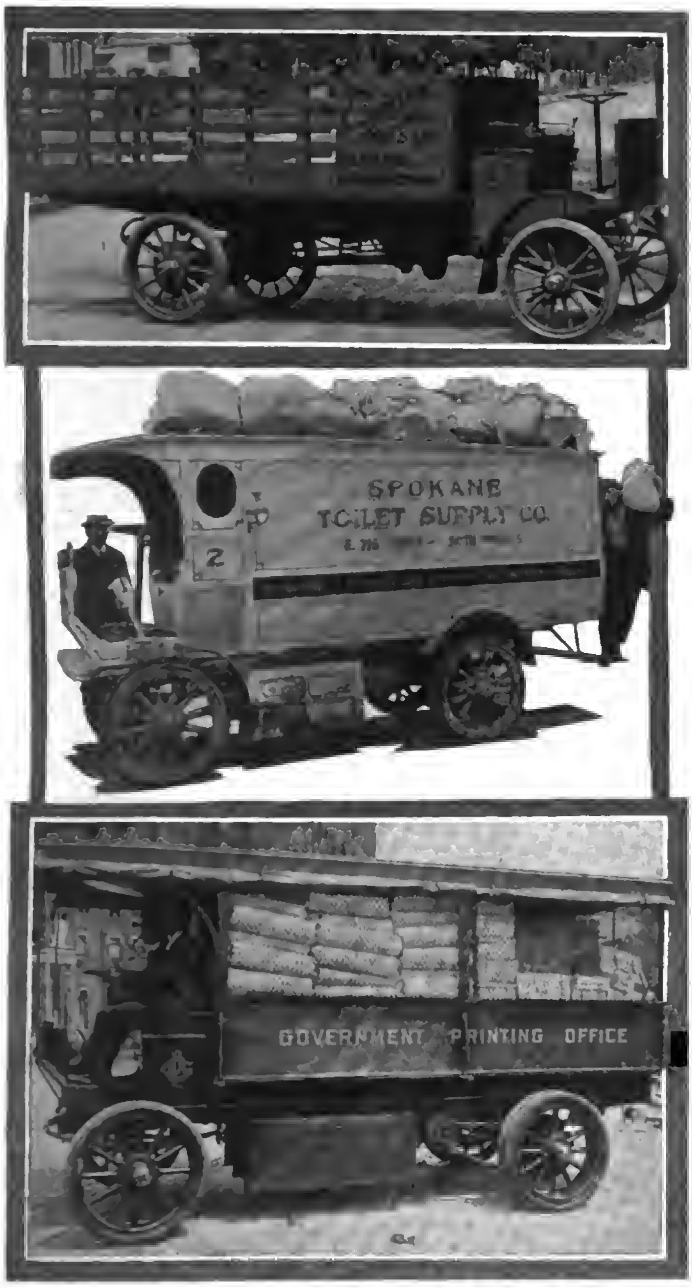
Center—Example of the C. T. 2-ton type for delivery purposes
Lower—2½-ton Walker wagon for department store delivery



3½-ton General Vehicle with deep express body

Baker

¶ These trucks, manufactured by the Baker Motor Vehicle Company, are made in five models ranging from the 500-pound to the 3.5-ton truck. The five models are as follows: Type W, 500 pounds; Type X, 1,000 pounds; Type O, 2,000 pounds; Type U, 4,000 pounds, and Type C C, 7,000 pounds. Perhaps the most conspicuous model is the C C type, intended to carry 7,000 pounds. The detailed construction of this chassis does not show any radical departure from standard practice, with the exception that the side driving chains are inclosed in oil baths, which keep the chain running free from the abrasive effects of dust and



Upper—Ohio 1-ton truck for general contracting work

Center—Baker 1-ton vehicle with body suitable for special laundry work

Lower—Baker 2-ton truck with body suited to work in government printing service

mud. The batteries in all vehicles are underslung in a substantially braced cradle and consist of forty-two cells for standard equipment, subdivided into small trays, or when Edison batteries are specified sixty cells of this type are used.

The controller, of the continuous-torque drum type, is inclosed in an aluminum case attached to the front part of the chassis under the floor-boards, and is operated by a lever beneath the steering wheel. A special safety device prevents accidental slipping into reverse. All models from 1,000 pounds upward have five forward speeds and three reverse. In these models the motors are suspended from a tubular cross-member of the frame. The power is transmitted to the inclosed differential by a Renold silent chain, inclosed in an extension of the differential cover. The final drive is by two roller chains from the jackshaft sprockets to the rear wheels, the alignment of the rear axle being taken care of by means of radius rods with easy adjustment. Two brakes outfitted, one of the internal expansion type working on the rear wheel hub drums and operated by a lever, and the other, also internal expanding, on the countershaft and drums, pedal operated. In order to facilitate lubrication of the various working parts, provision has been made whereby this operation can be performed from the exterior of the chassis without disturbing the body or load.

Champion

¶ These vehicles, manufactured by the Champion Electric Vehicle Company, are offered in two capacities, 750-1,000 pounds and 2,000 pounds. The batteries of these trucks are carried upon the chassis frame under the driver's seat. The battery equipment of the 1,000-pound chassis is twenty-six cells lead, eleven plates, or forty cells Edison A4, and that of the 2,000-pound chassis forty-four cells lead, thirteen plates, or sixty cells Edison A4 or A6 type.

The motor is suspended from a cross-member of the frame about the center of the chassis, and the power is transmitted to a pressed-steel rear axle, the first reduction being obtained by bevel gear and the second by spur gears. This type is common to both models. The purchased has the option, however, in the larger model of chain drive. In this case the first reduction is by silent Morse chain from the motor to countershaft, and thence to the road wheels by roller chains. The wheelbase of the small model is 86 inches, and 100 inches for the larger. The maximum speed of both trucks is 12 miles per hour.

Commercial Truck

¶ The trucks manufactured by the Commercial Truck Company of America comprise models for the following carrying capacities: 500 pounds, 1,000 pounds, 2,000 pounds, 4,000 pounds, 7,000 pounds and 10,000 pounds. The battery equipment of all models consists of forty-two lead or sixty Edison cells, the number of plates and type depending upon the service requirements and the size of the truck. The battery unit is suspended on all models from the main frame in a cradle suitably trussed both front and rear.

A feature of these trucks lies in the location of the controller, which is situated at the base of the steering column and operated by a wheel immediately below the steering wheel. Three forward speeds are furnished on the 500 and 1,000-pound chassis, while all the larger models are fitted with four speeds forward; two reverse speeds are provided in all cases.

There are three distinct types of drive represented in this line of trucks, the differences being such as to necessitate a separate description of each. Dealing with the lightest model first, comprising the 500 and 1,000-pound wagons, the final drive is by Hindley worm. The motor and rear axle form one unit, the power being transmitted to the jackshafts with one single reduction. The entire mechanism is completely inclosed, running in oil. The rear axle is of the floating type, the road wheels being mounted on Timken bearings. In the event that some repairs may be found necessary at any time, such as when it is proposed to overhaul the power plant, the entire rear construction can be removed in a very short space of time and a new

Couple-Gear with stake body; each wheel carries a motor
National Express Company's Detroit wagon with canopy top

or spare one substituted, thereby avoiding the necessity of laying up the truck. Internal expansion brakes are fitted to drums on the driving wheels controlled by a pedal. An electrical emergency brake is provided. The mileage claimed for these models ranges from 40 to 60 miles on a charge.

The points of variance between the preceding type and the 1 and 2-ton chassis lie in the form of drive. The rear axle is in the form of a double U-beam structure, the two beams being parallel to each other with the motors, of which there are two, placed between the beams and supported by them. The motors are geared directly to each of the rear wheels by a spur gear. The claim for this type of drive is that equal driving power is available at both wheels, thus obviating one of the drawbacks of differentially-driven wheels. The wheel that has the stronger footing in the case of the double-motor drive will revolve equally as well as the one that has the poorer footing. The motors are attached to gear-cases of crucible steel, the chassis springs finding a seat upon the top of the cases and the extension of the cases form the axle spindles. The armature shaft has a pinion attached at one end which meshes with three spur gears, these latter being carried on studs integral with the drive sbaft, which passes through the axle spindle and engages with the wheel hub by means of a square coupling.

The 3.5 and 5-ton types are fitted with four-motor, four-wheel drive. The two axles are steel forgings, made in two parts, separated by a spacer. The motors are held in position between the axle arms by means of bosses bored out to receive the trunnions which are part of tbe motor casing. Suitable bracing is provided to keep the motors in line. Each motor shaft is furnished with a driving pinion, whicb engages with a larger pinion upon a common axis with the main driving pinion. This latter engages with an integral bolt bolted direct to the wheel.

Detroit Electric

¶ The Anderson Electric Carriage Company's line consists of four types. The three types manufactured heretofore are continued, namely, 1,000, 2,000 and 3,000-pound vehicles, to which has been added a 7,000-pound model known as No. 7. The No. 7 truck is equipped with Edison batteries only, there being sixty cells of the A10 type. These cells are carried in four roller cradles, in a sheet steel compartment so arranged as to pull out at the sides on a special metal track. The operation can be performed by one man by taking off the cover on the side, attaching the metal tracks to slots in the lower corners and suspending them with hooks at the upper corners, thereby providing a shelf for carrying the batteries when withdrawn for inspection.

The disposition of the cells on the 1,000, 2,000 and 3,000 chassis is by placing eight trays parallel to one another with eight cells in each tray, except one, in which there are only four. In model No. 7 there are twelve trays with five cells in each.

The controller is of the continuous-torque type, operated by a lever carried below the steering wheel. In all models the motor housing is formed integral with two strap arms resting on two cross-members of the frame. The power is transmitted to the differential by means of inclosed Renold silent chain. Tbe final drive is through sprockets and double roller chains, S. K. F. self-aligning ball bearings being used in the countershaft brackets.

The frame on the new No. 7 model is 6-inch channel pressed steel, tapering from just in front of the center cross-member to a point immediately behind the driver's seat, at which point another cross-member is attached. This gradual sweep eliminates abrupt bends in the frame, thereby adding greatly to its solidity. The two brakes are operated by pedals, the service on the rear hubs and the emergency on drums attached to the jackshafts.

Fritchle

¶ These vehicles are manufactured by the Fritchle Automobile & Battery Company in one model for commercial purposes, with a carrying capacity of 1,000 pounds. The batteries, which are of Fritchle manufacture, are suspended amidships, consisting of thirty-two cells. The controller, placed under the driver's seat, is operated by a lever, giving five forward speeds. The motor is placed across the chassis and suspended from a cross-member, driving the large sprocket, attached to the differential in the rear axle, by single roller chain. The chassis frame is made of wood sills and treated so as to render them impervious to acids, the suspension being taken care of by elliptic springs, front and rear. with two reach rods connecting the front and rear axles holding them in line. The wheelbase is 100 inches. Two contracting band brakes are provided on the rear wheel hubs in addition to an electric brake.

Detroit electric with typical express body and good driver's protection

Atlantic 5-ton vehicle in brewery service

Atlantic 3.5-ton type with body suitable for the paper trade

Waverley 2-ton model with side doors

G. M. C. Electrics

¶ These vehicles are manufactured by the General Motor Truck Company in the following sizes: 1,000 pounds, 2,000 pounds, 3,000 pounds, 4,000 pounds, 6,000 pounds, 8,000 pounds, 10,000 pounds and 12,000 pounds, respectively described as Models 1, 2, 3, 4, 6, 8, 10 and 12. These again are subdivided each into three types according to the length of the wheelbase, the shortest being type A, the medium type B and the long wheelbase type C.

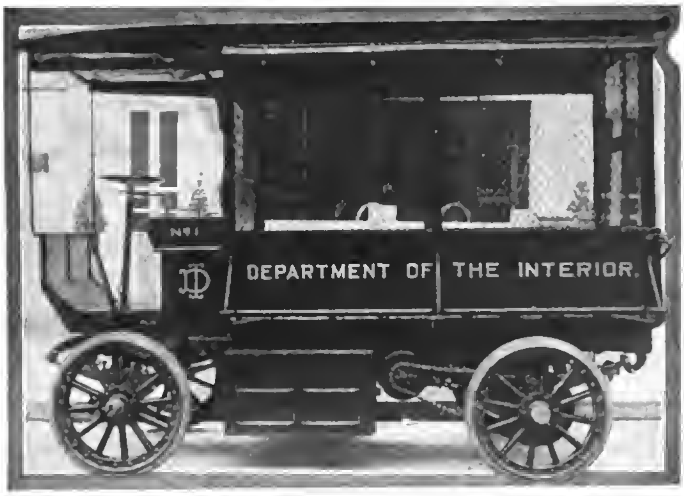
Three outstanding features distinguish these trucks from others on the market. One is a spring steel tempered blade propeller shaft to transmit the power from the motor to countershaft. The second is a short hood in front of the vehicle, inclosing the controller, ampere-hour meter, safety switch and light switches. The third is that the storage battery is placed on the chassis under the driver's seat. The battery, consisting in all cases of forty-four lead or 60 Edison cells, is carried above the frame, access to which is obtained by raising the seat cover. The cells are carried in single or multiple trays removable through the side panels. The steering pillar is inclined towards the rear, and carries a rod connected at the lower end with the controller and at the upper extremity with a lever above the steering wheel. The movement of the lever forward produces the five forward speeds and two reverse is obtained by moving the lever in the opposite direction. The motor is suspended from cross-members of the frame at the rear of the countershaft, the drive being transmitted as has already been explained by means of a spring steel blade. An expanding brake is fitted to the drive shaft and the conventional internal expansion brakes are fitted in the rear wheel hub drums. The semi-elliptic springs are supplemented at the rear of the chassis by coil springs being interposed between the chassis frame and the axle seats.

General Vehicle

¶ The General Vehicle Company manufactures six models; including chassis capable of carrying 750 pounds, 1,000 pounds, 2,000 pounds, 4,000 pounds, 7,000 pounds and 10,000 pounds. This season's models will not be marked by any material changes in design. The same general features are incorporated in all of the models, only small alterations in design being made to take care of the differences in load capacities. The batteries, consisting of forty-four cells, are suspended amidships under the main frame by stout section supports, loading and unloading being effected from either side. The controller is placed under the driver's seat, operated by a lever to the left of the driver. The motor is centrally located towards the rear of the chassis, the power being transmitted to the countershaft by an inclosed Morse silent chain, and thence to the rear wheels by double roller chains. An internal expansion brake is located in the drums of the rear wheels, which run on roller bearings.

Jatco

¶ Jatco vehicles, manufactured by the Joliet Auto Truck Company, are made in two models, one a 1,000-pound chassis, Model C, and the other a 1-tonner, Model D. The two are identical in dimensions as regards loading space, wheelbase and total overall length. The smaller chassis weighs 2,600 pounds and the larger model 3,000 pounds. Motive power is transmitted to the differential by silent chain and from the jackshafts by roller chain. Batteries with a 165-ampere-hour capacity, containing thirty and forty cells respectively for the model C and D, and suspended under the chassis. They are capable of supplying sufficient current for 50 miles for the smaller and 40 miles for the larger truck on a single charge. The control lever of the 1,000-pound



Baker 1-ton wagon for government service

chassis is located on the top of the steering wheel, and in the 1-ton chassis it is situated on the right of the driver's seat. Two independent pedal-operated brakes are fitted.

Lansden

¶ The Lansden Company builds five models, ranging from 1,000 pounds to 5 tons. The design of all the models is identical, the only differences being in the sizes of the parts, which are proportionate to the carrying capacity. The new models carry the following loads: 1,000 pounds, 1 ton, 2 tons, 3.5 tons and 5 tons.

Edison batteries, used on all models, are suspended from the frame in a steel cradle with aluminoid covering, suitably lined with insulating material. The side doors are hinged at the bottom and when lowered form an extension tray to permit the batteries being partially withdrawn. The trays are mounted upon steel rollers, which run in channels. With the exception of the 1,000-pound wagon, in which the cells are arranged in ten rows with six cells in a row, the four models have the cells arranged in twelve rows with five cells in a row.

The controller is fitted in front of the chassis below the floorboards and is of the eight-finger continuous-torque type, the operation of changing the four forward and two reverse speeds being effected by a lever under the steering wheel. Around the inclined steering post there is a tube, connected at the top end with the control lever, and at the bottom to an arm carrying an arc-shaped gear which engages with its mate on the controller shaft. Each speed is determined by notches in the quadrant upon which the change-speed lever works, and to prevent an inadvertent dropping into reverse it is necessary to slightly raise the lever. The maximum speeds of the respective models, starting with the smallest, are: 14, 12, 10, 9 and 8 miles per hour. The 1,000-pound and 1-ton chassis are capable of covering 60 miles per charge under normal conditions, and the three larger types average approximately 50 miles.

A series-wound General Electric motor is suspended from a U-section pressed steel cross-member, slightly forward of the rear axle, with the armature shaft parallel with the side members of the frame. The motor housing is bolted to an extension of the differential casing, by which means the motor and differential are held in alignment. The armature shaft, carrying the driving bevel pinion, is extended forward into the differential housing and a brake drum is attached to the shaft between the two units. In order to prevent any lubricant leaking from the differential and finding its way into the brake mechanism, a stuffing box is used. Side strains are obviated by the three-point suspension. It is claimed that the motor is capable of withstanding a 300 per cent. overload for a period of 30 minutes. Ball bearings are employed in the motor and roller bearings in the differential. The final drive from the inclosed jackshaft is by chains. The service brake on the armature shaft is operated by a pedal which is connected with the controller, so that the act of braking automatically cuts off the current to the motor. The emergency brake, pedal operated, is placed in the drums of the rear wheels, and can be held in any desired position by means of a ratchet.

M. & P.

¶ Two chassis models are manufactured by the M. & P. Electrical Vehicle Company, resembling each other in general characteristics and intended to carry 1,000 and 2,000 pounds. A resumé of one of these chassis will therefore be indicative of the other. The Westinghouse motor is suspended beneath the chassis frame directly under the driver's seat. In order to make room for the drive shaft from the motor to the differential, the battery box is made in two compartments, suspended from the side-members of the chassis frame. The Gould batteries are assembled in four trays, with ten cells per tray and are reached through a door in the floor. A rubber curtain protects them. Battery removal is from the sides. The controller of the continuous-torque type, operated by a lever on the left, gives four forward speeds and two reverse. The drive shaft from the motor to the differential is fitted with universal joints at each end to relieve any strains due to frame distortion. Final drive is effected by roller chains. Internal expansion brakes are fitted to the extremities of the jackshafts as well as to the rear wheel hubs, each set being operated by independent pedals. The chassis is of standard steel channel, with channel steel cross-members, hot riveted, and the suspension is by elliptic springs. The length of the loading space is 80 inches on the 1,000-pound chassis and 90 inches on the 2,000-pound chassis; the wheelbase is correspondingly longer for the larger chassis, namely, 112 inches, while that of the smaller type is 100 inches. Solid tires, fitted to standard S. A. E. rims, are supplied as part of the regular equipment.

Urban

¶ The Kentucky Wagon Manufacturing Company builds trucks in four sizes—of 1,000, 2,000, 4,000 and 7,000-pound capacity. All models are similar. The batteries are carried forward of the jackshaft beneath the frame. Access to the cells may be had from either side of the car or from the top. The steering column is inclined 30 degrees and the controller is operated by means of a lever mounted just beneath the steering wheel. This lever operates in the lower slot of a gate for the four forward speeds and in an upper slot for the two reverses, accidental movement of the lever being prevented by means of a thumb latch. The controller handle serves to rotate a tube, concentric with the steering column, being coupled to the controller at the lower extremity by a drag link. The controller, lighting and emergency switches, ampere meter, etc., are mounted in a short shroud, which is part of the chassis. The switches are mounted upon a panel at the rear of the shroud, forming as it does a dashboard, and by removing an aluminum panel the controller is readily accessible.

A General Electric motor is supported under the chassis immediately forward of the rear axle, whence the power is transmitted to the differential by silent chain, inclosed in an oil-tight aluminum casing. A cast steel housing is provided for the jackshaft unit. Nickel steel heat-treated gears and shafts are used to convey the power to the sprockets at the ends of the jackshafts, the final drive being effected by roller chains. The radius rods are arranged to provide for universal movement of the axle in relation to the chassis frame, thereby relieving the latter of undue torsion strains. Service brakes placed on the extremities of the jackshafts are operated by pedal, and emergency brakes expanding in drums on the rear wheels are operated by a ratchet-retained lever.

Walker

¶ The vehicles made by the Walker Vehicle Company are distinctive in design. Five models are listed, namely, Model F, 750 to 1,000 pounds; Model 7, 1,500 to 2,000 pounds; Model B, 3,000 to 4,000 pounds; Model D, 4,000 to 5,000 pounds, and Model E, 7,000 pounds. The general appearance of the vehicles is distinctive through the wheels, both front and rear being made of pressed steel disks with radial corrugations in the form of spokes.

The battery, the number of cells depending upon the size of the truck, is suspended by means of substantial cradles of T-section steel, the removal being effected from either side. Provision is also made for inspection from above through a trapdoor and cover. The rear axle houses the entire power-transmitting mechanism, the whole unit being known as the Walker balance gear. The power is furnished by a single motor having a hollow armature shaft mounted on ball bearings. The armature shaft drives the differential, which in turn drives the jackshafts. These carry at their outside extremities pinions which transmit the power through idler gears to large internal gears fastened to the driving wheels at a point near the outside periphery.

A U-shaped cover over the rear axle casing affords ready access to the motor at any time. By removing the hub caps, withdrawing the jackshafts and unbolting the saddles that hold the armature shaft in position, it is possible to remove the armature with a minimum of trouble. The suspension of these trucks is worthy of mention. The forward end of Models F, C and B is suspended by means of reverse semi-elliptic springs placed transversely across the chassis, the alignment and distancing of the front axle being maintained by a triangular reach extending from the extremities of the axle to the rear support of the battery box, where the two ends unite in a ball joint, permitting the axle to assume any angle with the road surface without being subjected to twisting strains. The rear suspension on all models is of the three-quarter platform type. The steering is vertical and the speed control is operated by a lever to the driver's left. The braking mechanism is entirely confined to the rear wheel drums.

Waverley

¶ Electric commercial vehicles manufactured by the Waverley Company include a 1,000-pound delivery wagon, 1, 2, 3.5 and 5-ton trucks. The 1,000-pound wagon is an enlarged model of last year's 600-pound chassis. Some minor changes have been made in the 1-ton model. The 2, 3.5 and 5-ton models are all new.

The battery in all models consists of forty-two cells, the number of plates varying according to the size of truck and is suspended from the chassis in a steel cradle, strengthened by T-section hoops and steadied by the guy rods between the front and rear of the base and the main frame.

The method of drive on the 1,000 and 2,000-pound trucks is identical, being the Waverley patented shaft drive with two reductions, the motor being hung slightly forward of the rear axle. The armature shaft is extended at both ends, one end carrying a brake drum and the other the driving pinion. The motor housing is also extended to inclose the silent chain which drives the secondary shaft. The latter is parallel with the rear axle and carries at its opposite extremity a herringbone gear which meshes with the main differential pinion, the power being transmitted to the rear wheels by dogs interposed between the ends of the jackshafts and the castellated hub ends.

Turning to the larger models, these possess all the earmarks of carefully studied construction, having a clean-cut, substantial appearance. The chassis are of channel section steel with cross-members of like material, securely riveted together and reinforced by angle and flitch plates. The motor is supported behind the rear axle by two semi-circular brackets passing below, while steel bands hold the unit in position above. These upper brackets are hinged, thus facilitating the removal of the motor at any time. An intermediate shaft fitted with universal joints at either end transmits the power to the differential, which is housed in a pressed steel casing. Back and front covers are fitted to the casing, permitting the removal of the entire differential without disturbing the anchorage of the casing. A truss bracket is fitted slightly off center, connecting the differential casing to a cross-member of the frame, in addition to two radius rods, which take the thrust of the rear axle and maintain the distance necessary for the final chain drive. All the power wiring is carried in a frame especially for the purpose, running the entire length of the chassis, thus preventing it from deteriorating through friction, vibration, etc. The controller, located under the driver's seat in all the larger models, is of the continuous-torque type and permits of an equal number of speeds forward and reverse. As this works in a quadrant there is no likelihood of the driver inadvertently passing from forward into reverse. Two pedals, one on either side of the steering pillar, control a set of brakes, the service brake being housed in the rear wheel drums and the emergency at the extremities of the jackshafts. The front end of the chassis is protected by a bumper of stout U-section.

Ward

¶ Ward cars are built in four sizes by the Ward Motor Vehicle Company. These four chassis are entirely new models and are known by letters, which denote the carrying capacity as follows: EA, 1,000 pounds; EB, 2,000 pounds; EC, 3,000 pounds, and ED, 8,000 pounds, the capacity being exclusive of body and driver. The main idea has been to develop a line of trucks of uniform design, the appearance and design of the smaller vehicles being replicas of the larger models on a smaller scale. By this means each part can be numbered, and by stating the model it is possible for a customer to easily obtain new parts when needed.

The battery crade is substantially constructed of steel, the base being formed by cross-members of T-section steel on which the battery tray slides. The standard battery equipment consists of forty-two cells of the lead plate type or sixty cells of the Edison. The continuous-torque type of controller is located beneath the driver's seat. It gives four forward and two reverse speeds and is operated by a handle placed at his left.

The motor is a shunt-wound General Electric, suspended over the rear axle by suitable braces to two cross-members of the main chassis frame. The power is transmitted to the countershaft by a silent chain of the inverted tooth type, inclosed in a dustproof casing, and thence through double roller chains to the rear wheels. The speeds at which these vehicles are intended to travel have been set so as to keep the cost of upkeep low. Suspension is by semi-elliptic springs front and rear. U-section steel is used for the side-members of the chassis frame. This is being slotted midships to allow the compensating cross-rod operated by the brake rod and pedal to pass through and thus equalize the braking effort while taking care of any inequality of wear or adjustment.

The wheelbase of the respective models, starting with the smallest, is 84, 96, 114 and 132 inches, and the platform lengths 78, 96, 117 and 144 inches. Ward special electric tires are fitted to standard S. A. E. wheels, which give the purchaser an opportunity of having any tires fitted that he may desire.

Lansden vehicle for the express field

Motor-Generators and Rectifiers

Enable Private Owners of Electrics To Charge Batteries at Home from Alternating Current Mains; Are Also Used in the Public Garage

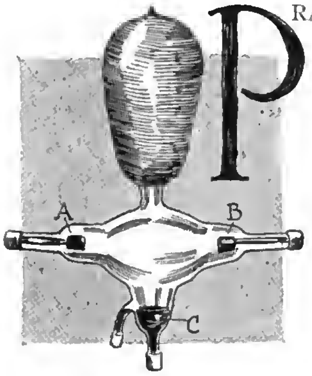


Fig. 1—Mercury bulb on Westinghouse rectifier

PRACTICALLY all the electrical energy produced by power stations at the present time is in the alternating form, that is, the current, instead of flowing continuously in one direction, is given alternate impulses in both directions. The electric vehicle, on the other hand, owing to the fact that it has to carry its energy in the form of a storage battery which only deals with direct current, requires that a direct current source of supply be available when recharging is necessary. In many of the smaller cities the use of the electric vehicle is almost entirely unknown, owing to the absence of public garages where battery charging can be done. Few garages for gasoline propelled pleasure or commercial vehicles have the equipment for renewing the energy of the electric vehicle. In every city of 5,000 population or over in the United States is at least one garage for the gasoline vehicle; in every city of 5,000 population or over there is a central station for the generation of electrical power; some of these central stations have facilities for charging electric vehicle batteries; most have none.

Various devices are in use for the conversion of alternating current to direct current, the most important being the motor-generator or converter, the mercury-arc rectifier, the electrolytic and the electro-magnetic rectifiers. All except the electro-magnetic rectifier, which, owing to its construction, is capable of dealing only with very small quantities of current, can be used for charging the batteries of electric vehicles.

The motor-generator consists of an alternating-current motor mounted alongside a direct-current dynamo or generator and coupled directly to it. When in use the motor is connected up to the alternating-current mains and, once started, there is a constant generation of direct current at the dynamo end of the combined set. Mechanically this type of converter is reliable, but there is a considerable loss of power in the process of conversion, especially in small models, resulting in a rather low electrical efficiency. Nevertheless the motor-generator, or rotary converter, which is the same machine in a different form, is the only practical method of converting alternating current on a large scale. Some efficiency is gained in the rotary converter over the motor-generator in that the former has only one magnet casing and armature. This armature has a winding fitted with collector rings at one end to take the alternating supply, and a commutator at the other end to deliver the direct current. This construction also does away with the difficulty of aligning the two shafts and four bearings of the two units of a motor generator.

The mercury-arc rectifier belongs to the static order of alternating-current converters, having no mechanically moving parts. The first of these devices were sold nearly 10 years ago, and since that time they have been in constantly increasing demand, the chief reasons for this demand being their high efficiency, absence of moving parts requiring oil and grease, and lack of vibration. This type of rectifier is also the cheapest reliable device for charging that has so far been produced. One of the objections raised against it was the presence of the glass tube which contains the mercury arc. It was predicted that this tube would not last, but as cases are known where the same tube has been in operation for 5 years, and the manufacturers of these tubes guarantee an average life of 600 operating hours, the slight cost of renewals need not be feared.

The mercury rectifier in its practical form consists of a glass vacuum chamber shaped very much like the ordinary electric

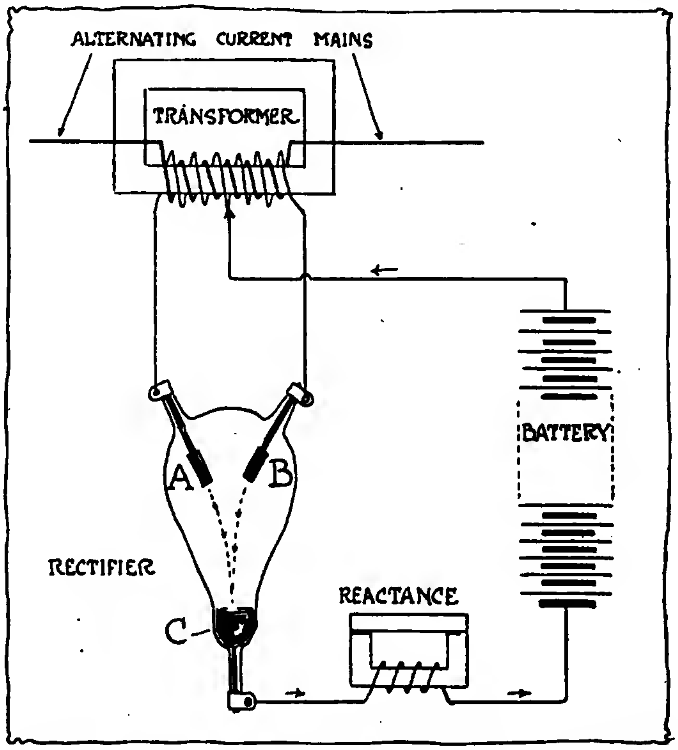

Fig. 2—Wiring diagram of mercury-arc battery-charging apparatus

light bulb except that it is larger, containing two anodes A and B, Figs. 1 and 2, and a cathode C at the base. This latter is the negative pole and consists of a pool of mercury with outer terminal connections. Graphite or iron is generally used for the anodes. The operation of the device depends on the peculiar property of mercury vapor, when of a certain rarefied density to permit current to flow from an anode or positive terminal across the vapor to a mercury cathode, but not in the reverse direction. Why this is so and exactly what happens in the process is not definitely known, but the theory of operation generally held is as follows: All gases are supposed to contain numerous electrically charged particles or atoms called ions. Some of these ions are positively charged and others negatively, and when a high degree of electrical pressure or potential exists between two conductors of electricity separated by a gas or gases such as air, these ions assume a directional flow between the conductors which becomes more rapid as the electrical stress increases, until a point is reached when an arc is formed permitting the current to bridge the gap. The ease with which an arc is formed depends not only on the voltage or pressure of the electrified conductors and the distance separating them but also on the density of the surrounding gas. When in a rarefied state a comparatively low electrical stress can break through. This is what occurs between clouds when lightning appears. The neighboring atmosphere is always rarefied, permitting an arc discharge between the oppositely electrified clouds. When this arc takes place in rarefied mercury vapor it allows current to pass only in one direction, and it was the discovery of this fact which led to its utilization as a sort of separator of the two alternate impulses which constitute alternating current, sending only the impulses of one direction to the battery or for whatever purpose the direct current was required.

When fitted up for battery charging the connections are as shown in Fig. 2. The alternating-current mains are connected to one winding of a transformer and the two anodes of the rectifier are wired across the second transformer winding. A reactance coil is introduced between the cathode at the base of the rectifier and the positive terminal of the battery, and the return wire from the other pole of the battery connects to the center of the transformer winding. Once the arc is formed the following action is taking place: The main alternating current passing around the first coil of the transformer sets up a magnetic state in the rectangular iron frame on which the coil is wound, which in turn induces a flow of current, also alternating, in the second transformer coil connected to the rectifier. The purpose of the transformer is to reduce the voltage of the mains to that which, after being rectified, is suitable for charging the battery. The induced current is now in communication with the mercury vapor through the two anodes A and B. These anodes are alternately positively charged at a rate corresponding with the periodicity or rate of impulses in the main supply, and at each instant of positive charge the current flows through the arc to the mercury cathode and thence to the battery. It will be seen, then, that virtually the arc is oscillating between the two anodes and the cathode, and that the resultant current supply, though unidirectional, is not absolutely "smooth." To neutralize the intermittent character of the current a reactance coil is inserted in the circuit.

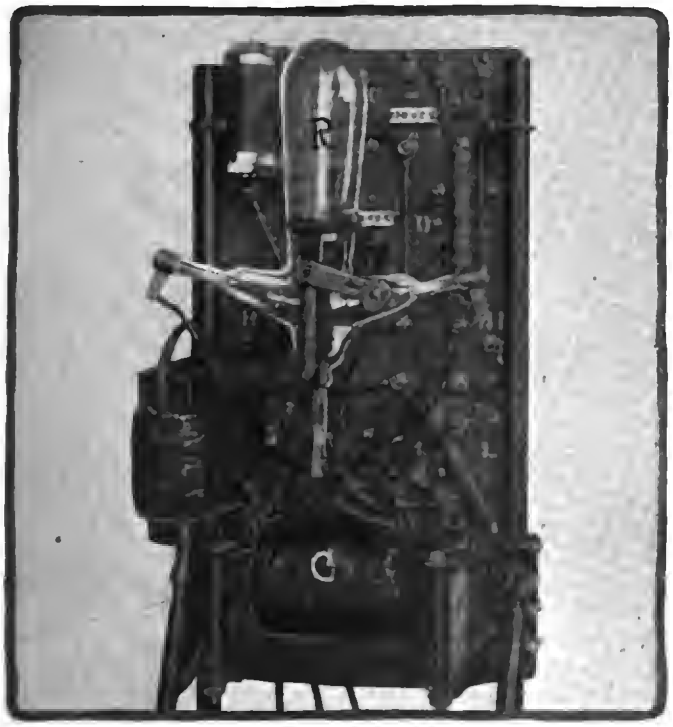

Fig. 3—Swivel-mounting of mercury bulb behind panel of General Electric Company's rectifier

It should be noted that there is a considerable drop of voltage during the process of rectification in the mercury bulb, varying in ordinary sized tubes from 15 to 25 volts. This drop is practically constant with a particular tube, and hence the efficiency of the rectifier can be said to vary with the voltage of the direct current delivered. The higher this voltage the less in proportion is the potential drop of the rectifier.

A line of motor-generator sets made by the General Electric Company and suitable for battery charging is shown in Fig. 3. The motors of these sets may be driven by either single, two or three-phase alternating current, at 60 cycles, and various standard commercial voltages. The capacities range from 0.2 to 10 kilowatts. Standard generators are shunt-wound, designed to deliver 125 volts at full load.

By a novel method of attaching motor and generator frames solidly together, these sets are made very compact and the necessity of a sub-base eliminated. This construction also allows the motor and generator armatures to be mounted on a common shaft, requiring only two end bearings. In all except the smaller sizes provision is made for thorough ventilation of the field coils, armatures and commutators, by a well-directed current of air, thus securing uniform, cool operating temperatures throughout, with consequent improved life of insulation.

Fig. 5 shows the Lincoln motor-generator set, a machine possessing an unusual feature in its ability to supply direct current at two distinct voltages. The low voltage is 75 and the high 115, being designed respectively to charge from twenty-four to twenty-eight-cell lead batteries or forty-cell Edison batteries from the 75-volt terminals, and from thirty-eight to forty-two-cell batteries or sixty-cell Edison from the high voltage end.

The Wagner rotary converter, made by the Wagner Electric Company, St. Louis, Mo., adapted for single-phase work, is shown in Fig. 4. It is a strong, compact design, suitable for fitting at any convenient point in the garage. The armature shaft runs on ball bearings and a belt pulley is provided so that the converter can be used as a motor for power purposes in the

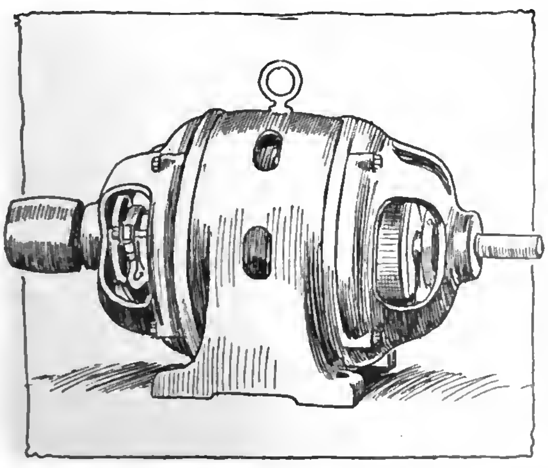

Fig. 4—Wagner rotary converter

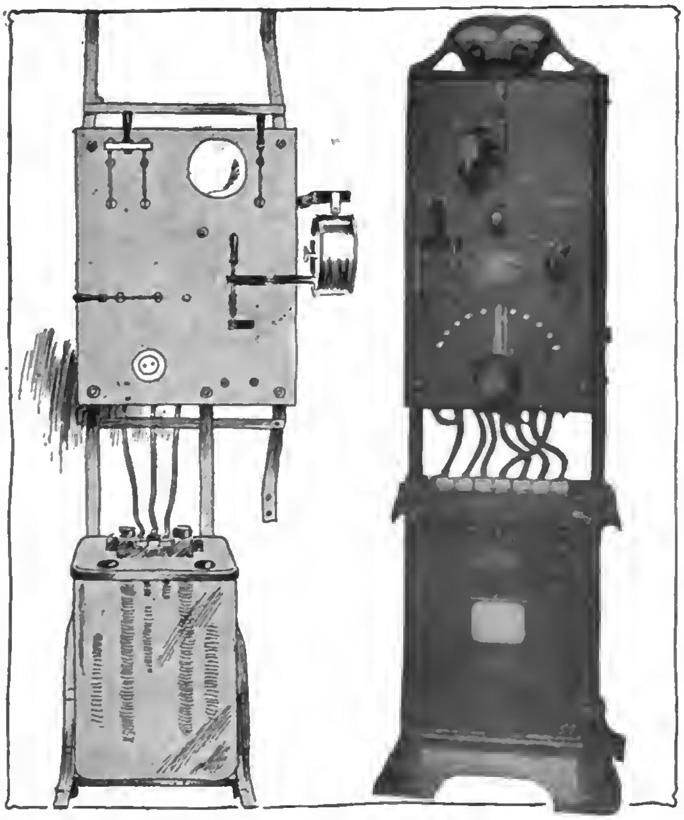

Figs. 6 and 7—Sirch electrolytic rectifier, and mercury-arc outfit by General Electric Company

garage, such as driving a tire pump, polishing wheel or lathe. As supplied, the equipment includes a control panel fitted with switches which control the amount of direct current delivered to the battery. When required, the makers supply automatic devices for cutting out the battery when fully charged.

Mercury-arc rectifiers are made in two standardized types by the General Electric Company. One of these, called the Runabout type, is shown in Fig. 7. As will be noted, the complete equipment consists of a panel with controlling switches and a main reactance forming a base on which the panel is mounted. The rectifier bulb is supported behind the panel in the manner shown at R, Fig. 3. On the main reactance are various connections to parts of the winding coil, which make it possible to connect the rectifier for various direct-current voltages which cover a range sufficient to charge all ordinary lighter "electrics." The main or compensating reactance stands on the floor and has two receptacles at the top for receiving the pipe supports of the rectifier panel. On the back of the panel is mounted a suitable tube holder for holding the mercury tube. In order to slightly rock the tube, which is necessary in starting, a small handle is provided on the front of the panel, which is connected to a small shaking rod. The panel is equipped with a main or alternating current line switch and single-pole circuit-breaker for protection against overload, and a starting switch for connecting the rectifier temporarily to a resistance load, due to the fact that it is difficult to start a rectifier against the counter electro-motive force of a battery. To start the rectifier the starting switch is held down with one hand while the tube is rocked with the other, and as soon as the tube starts, which is indicated by a greenish-blue light, the starting switch is released, and by means of a spring is transferred to the upper position, and the storage battery, to which the rectifier is connected, is automatically thrown on.

To obtain a regulation of the charging current a reactance coil C, Fig. 3, is connected in series with the alternating-current supply. This coil has eleven taps connected to as many buttons of a semi-dial switch, similar in many respects to the ordinary rheostat switch. This makes it possible to efficiently vary the charging current and voltage over the entire range required by any battery which the rectifier is designed to charge.

This rectifier is designed for operation on 60-cycle, 110 or 220-volt alternating-currernt supply. It may by slight modifications, however, be operated on lower frequencies than 60 cycles. From 220 volts the rectifier will charge from sixteen to forty-four cells of lead plate battery or twenty-five to sixty cells of Edison battery, and from 110 volts it will charge from fifteen to thirty-two cells of lead battery or twenty-five to forty cells of Edison, at a maximum charging rate, depending upon the capacity of the rectifier, which may be 30, 40 or 50 amperes.

Where more than one voltage battery is to be charged in a private garage and it is not convenient to change the connections frequently, the Universal or standard battery charging rectifier is supplied by the General Electric Company. This set is made in five sizes, or 10, 20, 30, 40 and 50 amperes capacity, and in direct-currrent voltages ranging from 10 to 100 when operated from 110 volts alternating current, and from 10 to 175 volts when operated on 220 volts alternating current. This rectifier is suitable for operation on 60 cycles or higher, but special sets of the same design can be furnished for lower frequencies.

The efficiency of these rectifiers at 60 volts direct current is about 70 per cent.; at 70 volts, 75 per cent.; at 100 volts, 78 per cent., and at 175 volts, 80 per cent.

The Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., builds mercury rectifier outfits in three models suitable for the private owner's garage. Each of these models consists of a special Cooper-Hewitt mercury bulb shown in Fig. 1, and stationary regulating apparatus, all contained in a ventilated iron case. At the top of the case two dial switches are fitted for regulating the charging current. The types are listed as Type AN, Type AA and Type AE. In Type AN an automatic switch is included, which cuts down the charging current as the charge proceeds, producing the "tapering current characteristic" desirable for lead batteries. Type AE is specially designed for charging Edison batteries which require a more constant rate of charge called the "flat current characteristic." The two first types are made in two sizes, either for ten to twenty-four cells or for twenty to forty-four cells. The maximum charging current is No. 0 amperes. The outfit for Edison battery charging is suitable for twenty to fifty-four cells, with a maximum current of 50 amperes. All these outfits are suitable for alternating-current circuits of 110 or 220 volts.

The Sirch rectifier shown in the drawing, Fig. 6, belongs to the class of electrolytic rectifiers. Here the unidirectional current is obtained by the chemical action between electrodes suspended in a special aqueous electrolyte contained in the glass cell at the base. No rheostat or transformer is employed. Back-discharging of the battery is impossible with this device, and should the main line current be interrupted at any time, charging of the battery is automatically taken up as soon as the main current is resumed.

Rheostats for Battery Charging

Safety Devices a Feature of Latest Designs—Solenoid-Operated Rheostat for Automatic Regulation of Current—Cast Iron Grid Type of Resistance Predominates—Other Types Are Enameled Wire and Compressed Graphite

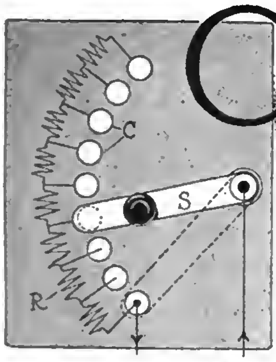

Fig. 1—Outline of rheostat

ONE of the requirements of efficient battery charging is that the charging current be of a certain voltage, determined by the number of cells forming the battery to be charged. And as most direct current supplied by electric power stations is higher than that required for this purpose it is necessary to adopt some means of reducing the main voltage to the desired amount.

There are two ways of accomplishing this reduction. A motor generator may be used, having a motor to take the higher voltage driving a generator to supply the lower; or resistances may be inserted in the circuit. Where the voltage of the supply mains is high, over 200 for example, the motor generator is the more economical method. Below this figure resistances are suitable. Either method represents a loss of energy depending on the voltage drop and may be considered therefore as an undesirable necessity.

The charging of batteries also requires that provision be made for varying the current throughout the charge. When a battery is connected up to a circuit and charging proceeded with, the gradual rise in the battery voltage causes the charging rate to decrease. In some cases this is desirable but the charging of Edison batteries and the periodic boosting or soaking charges which are beneficial to lead batteries demand a more constant charging rate and this can only be obtained by the use of regulating resistances or rheostats inserted in the circuit.

Lead batteries in use on electric vehicles range in size from 24 cells to 40 cells while Edison batteries are generally either of 40 cells or 60 cells. The voltage of the charging current required for all sizes extends from 62 volts in the smallest battery to about 110 volts in the largest. A lead battery of 24 cells requires a charging voltage of 62 volts; 28 cells require 72 volts, and 86 cells 104 volts. The current to charge 40 cells of the Edison type should be at 74 volts and for 60 cells at 110 volts. It will be seen, therefore, that a public garage, in order to accommodate its charging outfit to all these sizes and types of battery must, if only one voltage of supply is available, be provided with a large number of rheostatic resistances.

Fig. 1 shows diagrammatically one of these devices in its essential form. It consists of a switch arm S, the pivot of which is in electrical connection with the circuit and a series of contacts C arranged radially in the path of the switch arm, connected to a number of resistances R. The lowest of these contacts forms the other connection with the main circuit. By moving the switch arm downward over the contacts the resistances are cut out step by step until the final contact is reached when the current supply crosses the switch arm and no resistance is in circuit.

The capacity of a rheostat depends on the ohmic resistance of its units and the amount of amperes it can carry without overheating. Various metals are used for resistance material, iron being, perhaps, the most common. Iron or alloys may be used in the form of wire wound on an insulating core or simply suspended as a spiral in the air; but this method has been largely superseded by the use of flat grids of cast iron which present a large surface to the air for the dissipation of heat and are also constructionally convenient.

The Electric Products Company, Cleveland, O., manufacture automatic rheostats which are suited to the requirements of the private owner. Two of their standard types are shown in Fig. 2. Each outfit consists of a control panel supported on angle-iron uprights, behind which is mounted resistances of the castiron grid type. The instruments on both types are: A, a volt ammeter fitted with automatic cut-off mechanism; B, the main hand switch; C, automatic circuit breaker; and D, the charging rheostat. The automatic cut-off A is provided with two pointers. One of these is set at a point on the scale representing the fully charged condition of the battery and as the charge progresses the other pointer moves over until the two coincide when the charging circuit is automatically cut off. The two pointers remain in contact as a sign to the user that the batteries are fully charged. The battery-charging outfit shown to the right of Fig. 1 has been specially designed to produce automatically a constant charging current, such as is required by Edison batteries, by means of the solenoid-operated rheostat E. This switch automatically raises the charging rate as the battery voltage increases in such a ratio that the resulting current is constant. These charging sets occupy a floor space of 18 inches by 20 inches and are built for 30 or 50 amperes at 110 or 220 volts and charge from 10 to 44 cells of lead battery or from 20 to 70 cells of Edison batteries.

Another type of rheostat suitable for the private garage is shown in Fig. 3. These sets are made by the Cutler-Hammer Manufacturing Company, Milwaukee, Wis., and consist of two

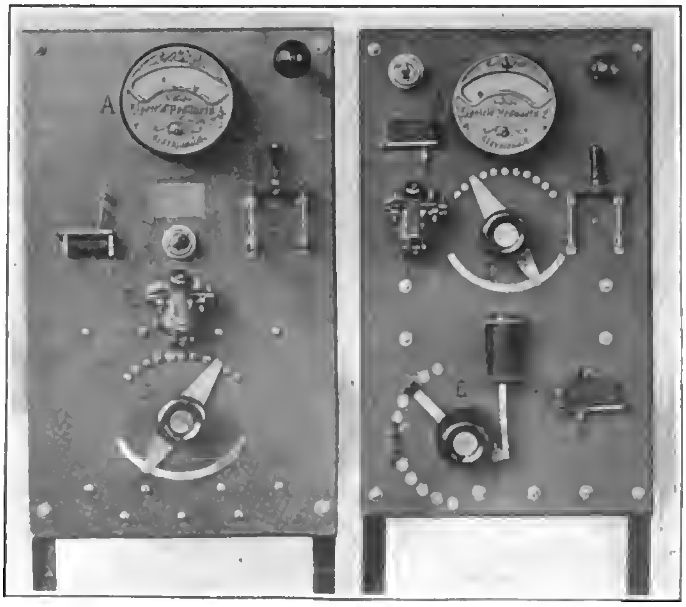

Fig. 2—Two types of Wotton battery-charging panels, that on the right being fitted with automatic solenoid-operated rheostat

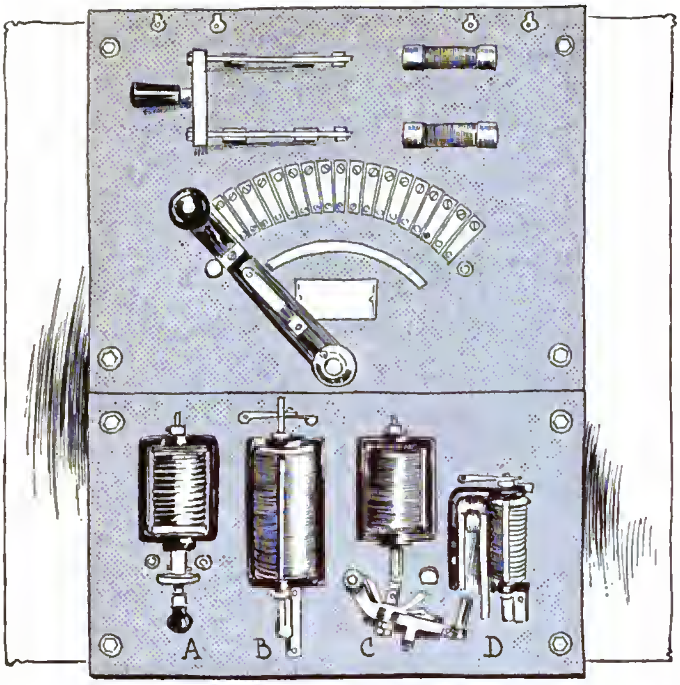

Fig. 3—Cutler-Hammer rheostat with automatic protective devices

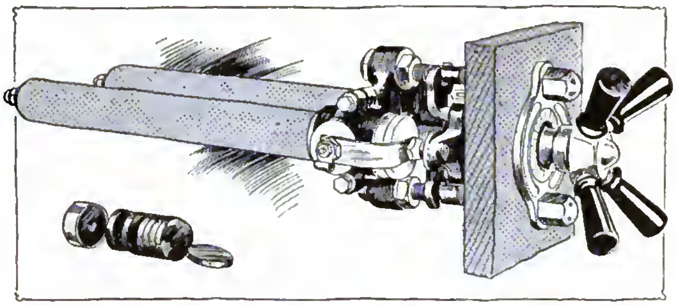

Fig. 4—Allen Bradley compression rheostat in which graphite discs form the resistance

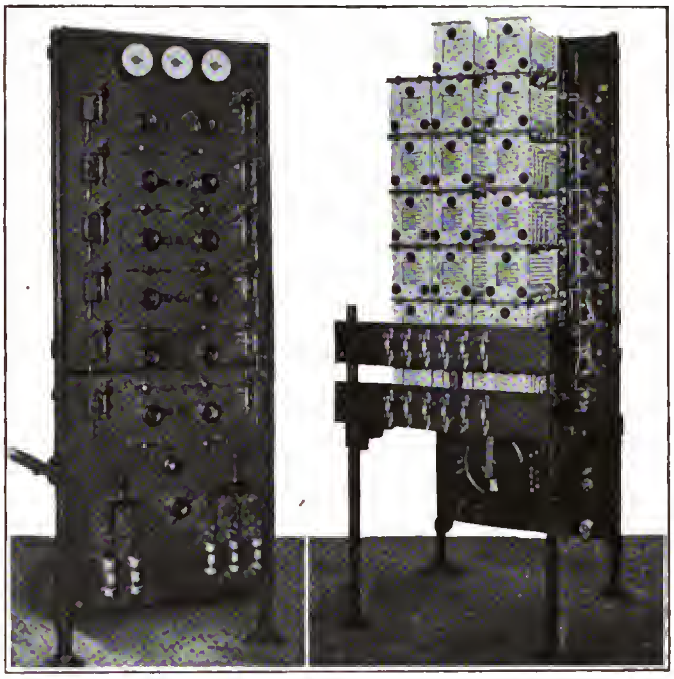

Fig. 5—Twelve-circuit rheostat set for a public garage, by the Westinghouse Electric Company

panels mounted together, one containing the main switch and the rheostat proper and the other the automatic protective devices. A is a low current cut-out which automatically opens the circuit if the current drops to a predetermined minimum. This prevents the battery from discharging into the line should the line voltage drop below that of the battery. B is a maximum voltage cut-out which opens the circuit when the battery voltage reaches the point at which the device is set to operate. C is a solenoid switch for opening or closing the main charging circuit. D is an overload circuit breaker to insure the battery against an excessive charging rate.

The operation of this type of battery-charging rheostat is as follows: After the battery and line connections have been made the operator first closes the knife switch and then moves the rheostat lever to the third contact segment, at the same time raising the plunger on the low-current cut-out A, thus energizing the solenoid switch C which closes the charging circuit and permits the current to flow through the resistance to the battery. As an additional protection the rheostat lever is provided with an electrical interlock which prevents the operator from closing the circuit to the battery except when the lever is in the off position, that is, with all resistance in circuit.

The same concern also builds these rheostats in multiple sets for public garage work. Fig. 9 shows a panel arranged with six rheostats, the two lower ones being discharge rheostats. This particular panel is for use with a motor-generator and the hand wheel and meter at the top are for the generator circuit. The two meters on the projection at the left, are for determining the rate of charge and the voltage of the batteries, any one of which can be switched on to the instruments when a reading is wanted. The instrument switch of each rheostat is situated directly to the right of the row of contacts, avoiding trouble and confusion in operation. When meter readings are taken the instrument switch does not break the charging circuit so that arcing at the blade is avoided.

The discharge rheostats at the base are a means of testing the electrical equipment of a car. For instance, in case of a vehicle not giving its rated average mileage and where some doubt exists as to whether the mechanical or the electrical equipment is at fault, the discharge rheostats can be used to determine whether the battery is capable of giving its rated ampere-hour capacity. If it does, then the fault lies elsewhere.

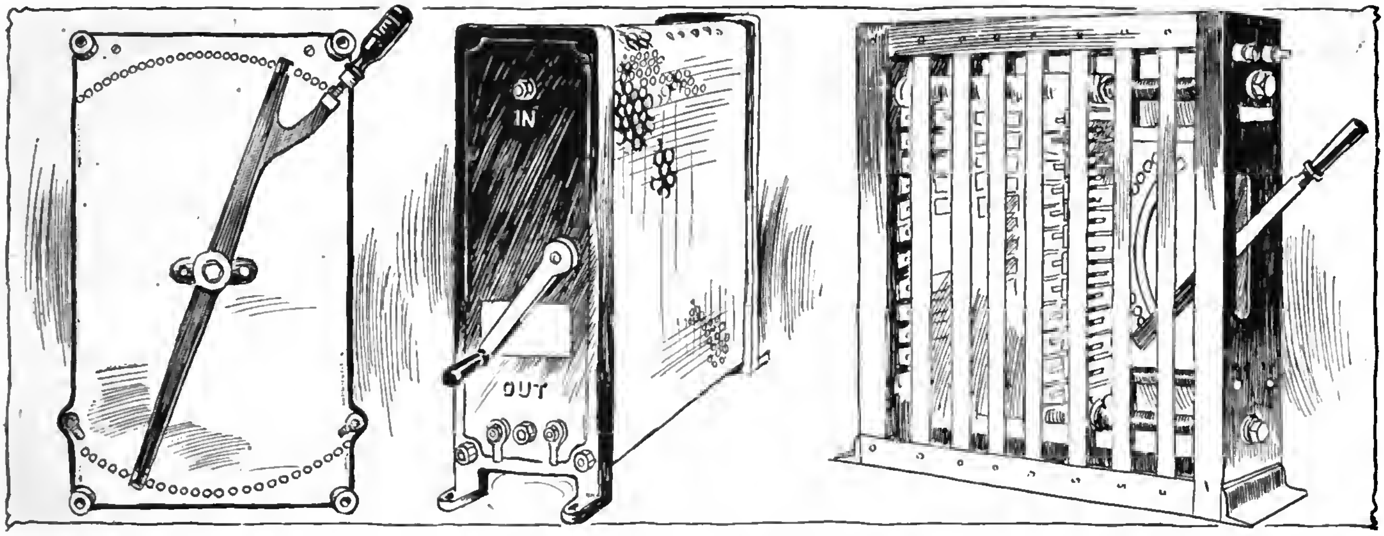
Front and rear views of a still larger charging set by the Westinghouse Electric Company, East Pittsburgh, Pa., are shown in Fig. 5. Grid resistances are used and the method of mounting these behind the panel is shown in the illustration. This board is equipped for twelve circuits, the rheostats being mounted behind the panel with the hand wheels only on the front.

The switches and regulator at the base of the panel are for controlling the motor-generator with which the charging set is designed to operate. The switchboard is equipped with a generator ammeter, a battery ammeter and a direct-current voltmeter; and for each charging equipment there is mounted alongside the rheostat wheel a single pole circuit breaker, a voltmeter receptacle for reading the individual voltage of each battery, and a single pole double-throw switch which throws the battery ammeter in and out of the individual circuit so that the charging current can be noted at any time.

The floor space required for this charging set is 36 inches by 30 inches.

Three types of rheostat units specially designed for banking in sets for large installations in public garages are shown in Figs. 6, 7 and 8. Each is self-contained and can, therefore, be used singly also, but they are made in a specially compact form suitable for arranging in a row, generally under the power switchboard.

Fig. 6 shows the Ward Leonard enameled plate type of rheostat. In this the resistance wire is embedded in enamel and cannot, therefore, suffer any depreciation by exposure to the elements. A flat switch arm provided with a projecting handle



Figs. 6, 7 and 8—Ward Leonard enameled plate resistance unit, and two types of grid resistance units by the General Electric Company and the Cutler-Hammer Manufacturing Company

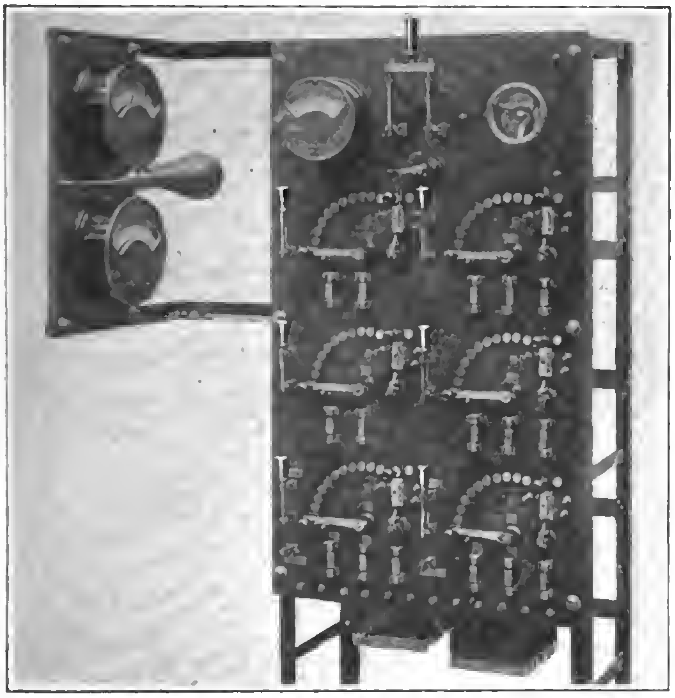


Fig. 9—Cutler-Hammer rheostat panel for six circuits provided with discharge rheostats

is strongly pivoted at the center of the plate and it will be noted that there are a great number of contacts permitting close adjustments of the current. The plates are 15 inches by 24 inches. When banked in sets they are spaced on tie rods passing through the four corners. A fixed resistance of a similar plate type is also made by this company, to be used in conjunction with the rheostat or variable resistance. By this means it is impossible to overload the rheostat if an operator should have too little resistance of the rheostat in circuit when the counter volts of the cells are low. The rheostat provides all the necessary variation.

The General Electric Company's CR211 rheostat, Fig. 7, is built in any capacity up to 90 amperes. It consists of two cast-iron end frames 16 inches high by 6 1-2 inches wide, connected by tie rods. These rods support the grid-type resistances in a vertical position and vary in length according to the capacity of the rheostat. The switch is mounted on a slate base immediately behind the front-end casting in such a manner that only the handle is exposed. Fifteen steps of resistances are provided. A perforated sheet metal cover, easily removable, extends from front to back and prevents accidental contact with live parts, without interfering with the ventilation.

Before charging, the handle should be moved up to its top position thereby inserting all the resistances into the circuit and preventing a large rush of current through the battery.

Fig. 8 shows one of the types of compact rheostats manufactured by the Cutler-Hammer Company. The resistances used are of the grid type and the rheostat panel is mounted inside with the handle projecting through a slot in the front plate. A standard height of 22 inches is adopted and the widths are 5, 7 or 10 inches according to capacity.

A rheostat which differs from all those previously described is the Allen Bradley compression rheostat, Fig. 4. Here the resistance is secured through the imperfect contact between the surfaces of prepared graphite disks piled in a column. This contact resistance varies with pressure, and the resistance changes are caused by subjecting the column to various degrees of pressure. The columns of disks are inclosed within an insulated steel tube, which is provided with suitable terminals and plungers for transmitting the pressure to the disks. Such inclosed columns constitute a complete resistance unit. The illustration shows a quantity of graphite disks such as is used and a complete rheostat of 1,000 watts capacity arranged for switchboard mounting. The graphite disks are well adapted for rheostatic service, as they will not crush or break, are not affected by any temperature that they have to encounter, cannot be fused, will not corrode and are not changed materially by years of service. These rheostats can be mounted directly on the back of the switchboard and take up very little space.

Harking Back a Decade

FROM THE AUTOMOBILE, January 3, 1903:

With New Year greetings to its readers *The Automobile and Motor Review* this week opens a new volume under the abbreviated title of THE AUTOMOBILE. The change in name will probably be welcomed by all. When THE AUTOMOBILE and the *Motor Review* were consolidated last June, it was thought best to incorporate both names in the title until the identity of the publication should have been thoroughly established. This, we believe, has now been done.—Editorial announcement.

Motorists in Chicago are up in arms over a proposed ordinance which, if passed, will compel them to carry an official number on the face of each lamp and also a number in 8-inch figures on the rear of the machine. A similar measure was passed recently by council, but was vetoed, and now it is bobbing up again with much apparent show of strength.

Charging a Battery

Being a Practical Outline of the Best Method

OWNERS of electric passenger and commercial vehicles are, when driving the car, careful to note the voltage and amperage readings on the measuring instruments of the vehicle; they have also read the varied instructions regarding care and maintenance of batteries; but **do these owners know what should happen to the battery when being recharged in the garage?**

To gain a clear concept of the modus operandi of charging a battery, consider a battery of twenty-four cells for a passenger vehicle. For convenience consider this battery an acid-type, lead-cell one (not an Edison cell), and that it is being charged from a 110-volt circuit direct-current supply, or should alternating current be the only available one then a rectifier would have to be used. For convenience throughout this article this current source of 110 volts will be known as the impressed voltage.

Example I—(These calculations are done with the number of cells in the battery and not the number of batteries.) The battery has twenty-four cells. A cell discharged to 1.8 volts is practically empty, or discharged as you may prefer to term it. With your battery so discharged the voltage available to run your vehicle is 1.8 volts × 24, a product of 43.2 volts. In equation this is

$$1.8 \text{ volts} \times 24 = 43.2 \text{ volts.}$$

This voltage is so low that you must recharge. The impressed voltage from the charging circuit is 110 and the battery voltage, which will buck or act counter to this impressed voltage during charging, is 43.2, so that your effective charging voltage is the difference between the impressed voltage and the counter voltage, or in equation

$$110 \text{ volts} - 43.2 \text{ volts} = 66.8 \text{ volts.}$$

Next consider the net result of this effective voltage on the battery: the internal resistance of the battery is so low as to be negligible. The equation is

$$\text{Current (amperes)} = \frac{\text{E (volts)}}{\text{Resistance (ohms)}}$$

From this equation it is evident that unless some form of resistance is inserted between the charging current and the battery the equivalent of a short circuit will result and such a large current or amperage will flow into the battery that it will be destroyed.

How much resistance is needed?

To determine this resistance assume that the data supplied you by the vehicle maker covering battery charging says, **"Maximum charging rate is 40 amperes."**

To charge at a constant maximum rate of 40 amperes we must have such a resistance as will not at any time permit more than 40 amperes current to enter the battery. Calculate as follows:

Impressed volts	110 volts
Counter volts	43.2 volts
Effective charging volts	66.8 volts
Maximum charging rate	40 amperes

With this information calculation is based on the equation

$$\text{Current} = \frac{\text{E (volts)}}{\text{R (resistance ohms)}}$$

$$\text{Or } 40 = \frac{66.8}{\text{R (in ohms)}} \qquad \text{or } R = \frac{66.8}{40}$$

$$\text{Or } R = 66.8 \div 40 = 1.67 \text{ ohms}$$

Example II—Consider that 40 amperes are entering the battery: instantly the voltage begins to rise and soon reaches 2 volts per cell, or a total for the twenty-four cells of 2 volts × 24 = 48 volts, which are counter volts. Now to calculate the requisite resistance proceed as follows:

Impressed voltage	110 volts
Counter voltage	48 volts
Net effective charging voltage	62 volts

But we still desire a charging rate of 40 amperes and must again use the equation (current = voltage ÷ resistance; or in other words resistance = voltage ÷ current) and we get

$$\text{Resistance (ohms)} = \frac{62}{40} = 1.55 \text{ ohms}$$

But we had 1.67 ohms in resistance, which is too much, and we must cut out the difference, namely (1.67 ohms — 1.55 ohms) .12 ohm, or, in other words, the resistance of the battery rheostat must be cut down this amount.

Example III—With this reduced resistance in circuit and 40 amperes flowing the battery voltage soon increases to 2.2 volts per cell, or a total voltage for the battery of (22 volts × 24) 52.8 volts, which of course is a counter or bucking voltage to further recharging. To determine the necessary resistance to allow 40 amperes to flow proceed as followed in Examples I and II, namely:

Impressed voltage	110.0 volts
Counter voltage	52.8 volts
Net effective charging voltage	57.2 volts

Using these figures in the equation (resistance = voltage ÷ current) we get

$$\text{Resistance (ohms)} = \frac{57.2}{40} = 1.43 \text{ ohms}$$

The present resistance, from Example II is 1.55 ohms, so that it is necessary to still further reduce this by (1.55 ohms — 1.43) .12 ohm.

Example IV—With this reduced resistance and the current flowing at 40 amperes the voltage per cell increases to 2.5 volts, giving a total for the battery of

$$2.5 \text{ volts} \times 24 = 60 \text{ volts (counter volts)}$$

To get the necessary resistance for this increased counter voltage we again proceed as in Examples I, II and III and get results as follows:

Impressed volts	110 volts
Counter volts	60 volts
Net effective charging voltage	50 volts

The necessary resistance is 50 divided by 40 or 1.25 ohms.

Deduction—From these four examples which show why a constantly reducing resistance is necessary in battery charging work, it is a natural deduction to infer the more steps in the reductions of resistance offered by the rheostat the better in making the reduction from 1.67 ohms to 1.25 ohms. **For charging a twenty-four cell battery at a 40-ampere rate practically all that is needed in a rheostat is to take care of a resistance reduction between 1.67 and 1.25 ohms in as many steps as possible, the more the better. Such a rheostat should be built to carry a 40-ampere current without overheating.**

Example V—Consider this case in which your battery has been fully charged to 2.5 volts per cell with 1.25 ohms resistance in the charging circuit; the car is taken out on the road and the next time it is charged the battery voltage is down to 1.8 volts per cell, giving a counter voltage for twenty-four cells of 43.2 volts or a net effective charging voltage of 66.8 volts, but your charging man was careless and only had 1.25 ohms in resistance instead of 1.67 ohms.

What would be the result?

Here it is: The current that will flow is 53.4 amperes instead of 40, the maximum charging rate of your battery, and with this current flowing unless the rheostat is designed for such it will overheat and burn out. This 53.4 amperes is obtained as follows: Current flowing = voltage ÷ resistance, which is 66.8 ÷ 1.25 = 53.4. This example teaches the first rule of good practice in battery charging, to wit: **"Always insert all of the resistance of the charging rheostat before closing the switch to begin charging the battery, or else the battery will be charged at too high a rate and the rheostat overloaded."**

This example demonstrates that unless a single-step resistance is used, permitting of not more than 40 amperes to pass at any time, some indicating instrument, such as ammeter or current indicator must be used. By watching such instrument the current is seen to be automatically cut below the 40-ampere rate, at which time the rheostat lever must be moved to cut out resistance until the meter reading shows 40 amperes flowing.

Overload Circuit Breakers—As a precaution against short circuits overload circuit breakers are often used as a wise precaution. Fuses as a precaution against overload are necessary, being required by law, but they are slow to act and are not always reliable. In our problem a circuit breaker set at 41 amperes is preferable and will give protection against short-circuits and the neglect mentioned.

For a given job of this kind the best rheostat at lowest cost is one designed for 40 amperes capacity throughout. It might be supposed that in a 40-ampere rheostat 1.25 ohms resistance should carry 53 amperes until an attendant notices his ammeter and corrects the resistance to be such that 40 amperes will pass. It must be borne in mind that the heat varies as the square of the amperage and that the overload is 13 amperes. But in heat it is $13^2 \times 1.25$ (the resistance), or 211 watts, which you note is a high figure. It actually is only 33 per cent. increase in amperes, but 75 per cent. increase in watts, which is heat.

However, it is often desired that instead of charging at the maximum 40-ampere rate for a short time the battery be charged at a low rate for a long time. For example, we want to set a rheostat for all-night charging and start with, say, 10 amperes, and as the counter volts of the battery increase allow the charging rate to be automatically reduced. It is then necessary to have such a resistance that the counter voltage in the battery rises to the value given in the following table:

Impressed volts	110 volts
Counter volts	43.2 volts
Net effective volts	66.8 volts

To allow 10 amperes to pass, then, 6.68 ohms resistance is required in the rheostat (66.8 ÷ 10 = 6.68). The rheostat is then designed to have a total of 6.68 ohms resistance, and of this 1.67 ohms must have 40 ampere capacity and the rest have a tapered capacity of from 40 down to 10 amperes of charging current.

Automatic Underload Circuit Breakers—You may here ask the question: Is it possible to leave a battery on charge and have it automatically become disconnected from the circuit when the battery is fully charged? Yes, this can be arranged by having an automatic underload ampere circuit-breaker in the circuit. **Calculate as follows:**

Impressed volts	110 volts
Counter volts at beginning of charge	43.2 volts
Net effective volts	66.8 volts

and 10 amperes are to pass—then 6.68 ohms resistance is in circuit. But the counter volts increase to be 2.5 volts × 24 = 60 volts and the net effective volts are reduced to 50. Then with 6.68 ohms resistance in current 7.4 amperes will pass (50 ÷ 6.68 = 7.4). Then a circuit-breaker set to automatically open the circut when the current is automatically reduced to 7.5 amperes will disconnect the battery and stop the charge.

Now consider that you have two cars—to be extreme I will say a pleasure car twenty-four cells, 40-ampere maximum rate, and a truck of forty cells, 60-ampere charging rate. We have the figures in the twenty-four-cell car. The figures on the forty-cell, 60-ampere maximum charging rate are:

Impressed volts	110 volts
Counter volts	72 volts
Net effective volts	28 volts

and allow 60 amperes to pass .466 ohms (28 ÷ 60 = .46) resistance is needed, which must be reduced to

Impressed volts	110 volts
Counter volts (2.5 per cell)	100 volts
Net effective volts	10 volts

Sixty amperes to pass requires .166 ohms resistance (10 ÷ 60 = .166).

Now let us assume that .16 ohms of this rheostat is in circuit, and the twenty-four-cell battery discharged is connected in circuit; then

Impressed volts	110 volts
Counter volts	43.2 volts
Net effective volts	66.8 volts

The resistance in circuit is .16 ohms; then 417 amperes (66.8 ÷ 16 = 417) will pass which would immediately tend to ruin the battery and burn out the rheostat. If the circuit is protected with a circuit-breaker, the breaker would operate and save the fuses. If no breaker were used, the fuses would blow out, but probably not in time to save the battery and rheostat from injury. Therefore **note that the breaker would have to be set for the truck at 60 amperes; yet the maximum allowable charging current for the pleasure car is 40 amperes, so the circuit-breaker is not a proper protection for it between these limits.**

The above figures show that if a battery rheostat is to be used with a fixed number of cells it can be made economically, also the battery can be charged properly without fear of injury, and it can even be set to charge and it will automatically stop its charge when full. The circuit can be properly protected against damage by automatic circuit-breakers. For proper charging an ammeter is necessary. The one on the car can be used and often is used.

Advice—These figures show that when the same battery rheostat is to be used to charge two cars or more with different numbers of cells then a rheostat must be made of a great number of steps so that the resistance can be greatly reduced and increased and also that overload protection by fuses and circuit-breakers is not readily obtained, the only way to properly charge the battery and protect the battery and entire circuit from abuse or destruction being to have skilled workmen who will always insert all of the resistance of the rheostat in circuit before closing the switch and who will then watch the ammeter carefully and adjust the resistance of the rheostat closely and often for proper charging.

The garageman who has cars carrying from twenty to forty cells per vehicle must install rheostats that will cover this range and have capacity from 60 down to 10 amperes. Such rheostats are very expensive compared to a single rheostat for a fixed number of cells; they must be protected against short-circuit and brains are needed to handle them.

With a proper knowledge of why the increased amperage will pass, perhaps some great care and attention in garages will cause proper charging and a greatly increased life of the batteries will result.

For Garagemen—Always insert all of the resistance of a charging rheostat before closing the switch.

Always watch your ammeter closely and maintain charging rates as recommended by the car manufacturer.

Occasionally trip and open the automatic overload and underload circuit-breaker to see that they are in proper operating condition.

Never charge a battery at too high a rate, even for a short time. Never overload a rheostat.—D. J. Burns, Ward Leonard Electric Company.

1913 Vehicle Batteries

Edison and Lead Batteries Continue with Few Alterations, But Developments Awaited for Near Future

Manufacturers Are Busy Improving the Electro-Chemical Qualities to Increase Life and Capacity of Product

BATTERIES constructed for the work of propelling electric vehicles have not experienced any radical development during the year just closed.. Whatever improvements have been made have been in the nature of small changes which tend to strengthen the battery and to lengthen its life. A great deal of chemical experimentation has been going on, as it always is, in this branch of electrical work, but few mechanical changes have been made. In this respect more than one step forward is expected to be taken by several companies during 1913.

One of the principal problems of the battery field is the guarantee situation. No settled position has been adopted by the host of makers, but several companies have made advances toward that goal. While some companies do not guarantee their product on the reasoning that once it leaves the hands of the makers and is subjected to the careless treatment of a driver, it is impossible for the maker to stand behind it, several concerns give a 1-year guarantee. The Ironclad Exide battery is even guaranteed for 2 years, or rather a period of 600 cycles during that time. In all probability this problem will be solved in the near future.

The Edison battery for vehicle-propulsion purposes is made in five sizes designated respectively A4, A6, A8, A10 and A12. The numeral in each designates the number of positive plates per cell, thus A6 has six positive plates and seven negative plates giving a total of 13 plates. There is always one more negative per cell than positive plates, thus A12 has twenty-five plates, twelve positive and thirteen negatives.

The Edison vehicle battery differs from all other storage batteries in that it is a non-acid type, in other words it is an alkali battery, but is more generally known as the nickel-iron battery because these elements are used as filling materials in the plates.

Another characteristic of the Edison battery is that the active material in the positive plates is filled into little perforated steel tubes so that with the vibration that the vehicle is subjected to when in operation this filling material cannot be shaken out and so the battery capacity is preserved, because whenever this active material is shaken out in any battery the battery capacity drops. The material in the negative plate is also put into little compartments, not tubes, but long, rectangular-shaped perforated pockets made of cold-rolled steel, nickel-plated, the same material as used in the tubes of the positive plate.

Look for a moment at each of these little tubes for a positive plate. Each tube is 4.25 inches long and approximately .375 inch in diameter. There are thirty of them in each plate. They are mounted vertically in two rows, one row across the top half of the plate and the other in the bottom half. These little tubes are made with the utmost accuracy. The tube is made from cold-rolled nickel-plated steel ribbon most carefully prepared for the job. It is then wound spirally by machinery, specially designed for this work, and when in tube form there are eight little steel rings slipped over the outside and spaced equidistantly, to add strength and to prevent any explosion.

Next comes the filling of this little tube, which is carried out with the utmost accuracy, for their must not be any variation, one must be filled identically with all others. In filling two substances are put in, one is pure metallic nickel in the thinnest flake form and the other is nickel hydroxide. These two are put in in layers, first nickel hydroxide and then the pure nickel flake. There are exactly 350 layers of each, 700 in all. This filling is done by specially designed automatic machinery. Each tube has exactly 700 layers. Tubes are regularly taken from each filling machine, cut in half longitudinally and examined with a microscope to see that this filling has been accurately done. When filled the tubes are carefully inspected, measured for length and the ends closed.

Next the negative plate: This is made up of long, rectangular-shaped pockets and each is filled with finely powdered iron oxide, which is put in with practically as great accuracy as to quantity as the filling in the little tubes of the positive plate. Twenty-four of these little pockets make up a negative plate.

In each cell of the battery the negative and positive plates are alternated, with narrowest strips of hard-rubber insulation between them. The jar into which the plates are placed is a cold-rolled steel one with all joints autogenously welded. The jar walls are corrugated to add strength. The jars or cells are in turn assembled in very light trays for convenience in battery handling.

The leading virtue of the Edison battery is its long life, due to the tube-and-pocket construction of the positive and negative plates which prevents falling out of active material because of vibration, and of heat in charging and discharging. The battery is also much lighter than the other types. The battery will stand very high charging rates and can be discharged at any rate to meet the service without injury. The tube-and-pocket construction permits of this. The battery is sold with a 4-year guarantee on cell capacity and a 1-year guarantee covering the defects in workmanship or material. When fully charged the voltage per cell is 1.85 and to get the required voltage for charging a battery it is necessary to multiply this by the number of cells in the battery. A twenty-four-cell battery requires 45 volts; a sixty-cell battery 111 volts.

Four Types of Exide Batteries

The Electric Storage Battery Company, Philadelphia, Pa., for 1913 offers four types of storage batteries for vehicle propulsion, namely, the Exide, Hycap Exide, Thin Exide and Ironclad Exide. Each type is furnished in various sizes, which depend on the numbers of plates used in each cell of the battery, the various models are classified under the heads MV and PV, according to the plate sizes. Taking up these four types in turn, the exide MV battery comes in eight sizes having seven, nine, eleven, thirteen, fifteen, seventeen, nineteen and twenty-one plates, respectively. No matter how many plates are used the voltage of each cell is the same only the amperage being subject to change, increasing with the total surface of the plates in the cell. The Exide MV sizes just enumerated have respective capacities of 84, 112, 140, 168, 196, 224, 252 and 280 ampere-hours. Exide PV comes in four sizes with five, seven, nine and eleven plates, respectively, the capacities of these batteries being 48, 72, 96 and 120 ampere-hours, respectively. The Exide type of battery is heavier than the Hycap and the Thin Exide types; it is more economical for trips of small mileage, especially if it is to be used on trucks and subjected to hard work. The Hycap Exide type has somewhat thinner plates than the Exide type, but like the latter comes in two plates sizes MV and PV. Nine sizes of MV cells are available, having nine, eleven, thirteen, fifteen, seventeen, nineteen, twenty-one, twenty-three and twenty-five plates, respectively, with capacities of 110, 138, 165, 193, 220, 248, 275, 303 and 330 ampere-hours. The PV cells come in three sizes with nine, eleven and thirteen plates, respectively, resulting in capacities of 93, 115 and 128 ampere-hours. The Thin Exides having, as its name implies, thinner plates than the two preceding types, is furnished in eleven MV sizes, which have from eleven to thirty-one plates, each type having two more plates than the preceding one. The capacities of these batteries vary from 130 to 390 ampere-hours.

The three Exide types just described are of conventional design in many respects. They have the staggered type of grid for both positive and negative plates, the former containing peroxide of lead in pasty form while the latter contain paste lead. To keep positive and negative plates properly spaced at all times separators of rubber and wood are used. The rubber is in form of a thin sheet perforated to permit of passage of the acid through it, while the wood plates are formed with projections on one side; these projections face the rubber sheets, one of which is in place on either side of each positive plate. Likewise, a wooden separator is arranged with one plain side at each side of every negative plate and has projections on the other side which hold the entire system properly spaced and insure also acid spaces adjacent to both sides of every plate. No provisions have been made to facilitate flushing of the jars as the plates rest on the high bridge under which there is plenty of space for dead material which has dropped from the plates.

The Ironclad Exide type of battery is, in a way, the leader of the line, being adaptable for all sorts of service and designed for a much longer life. It comes in eight MV sizes, having from seven to twenty-one plates with battery capacities of 94, 126, 158, 190, 220, 252, 283 and 316 ampere-hours, respectively. The Ironclad type differs from all others by the construction of the positive plates which are not built up on a staggered frame but are formed of a number of hard-rubber tubes with small passage for the acid in them; in these hard-rubber tubes the oxide paste is carried around a conductive core which is connected to a transverse contact rod in the top of the plate. All four sides of the plates are fitted with rubber strips vulcanized on to them to shield the hard-rubber tubes from shocks by too rough handling. The hard-rubber serves as insulator for the positive plates so that the rubber sheets used in the other types are not necessary in the Ironclad type; furthermore, a thinner wooden separator is used which affords more ample acid space between each two plates. Another improvement which has been incorporated in this type is the use of a special wood for these separators, which is called Gulf wood and placed in the jars with its grain arranged horizontally. Experiments of the Exide company show this to prolong the life of the separators.

The Geiszler Bros. Storage Battery Company, New York City, manufactures vehicle batteries to order although it has no standard product in this line. The vehicle batteries are of the non-sulphating type, and in construction very similar to the other Geiszler batteries, the sizes being determined by the specific requirements of the user of the battery.

U. S. L. Batteries Have Thick Plates

The United States Light & Heating Company of Niagara Falls, N. Y., and New York City make three principal classes of vehicle batteries distinguished by the thicknesses of their plates as WB, WBH and WBT. WB is the heaviest plate, being .210-inch thick, while WBH is of medium thickness, and WBT the thin type. In each case positive and negative plates are of the same thickness. The types CB and CBH of this company are not used extensively and we therefore will limit our attention to the three types first mentioned. The type WB comes in eight sizes, having from seven to twenty-one plates with an ampere-hour capacity from 84 to 280 if charges at a four-hour rate from 90 to 300 at a 5-hour rate, or from 97 to 324 at a 6-hour rate, likewise the capacity for work depends on the time in which the batteries are discharged. The WBH batteries include eight sizes, having from eleven to twenty-five plates, and ampere-hour capacities from 140 to 336 at a 4-hour charging rate, from 150 to 360 at a 5-hour rate and from 162 to 388 at a 6-hour rate. As to the WBT type, there are eleven sizes of cells having from eleven to thirty-one plates and capacities ranging from 125 to 375 ampere-hours at a 4-hour rate of charging, from 135 to 405 at a 5-hour rate and from 144 to 435 at a 6-hour rate. As in the case of the Exide batteries the heaviest types of plates should be used where a vehicle is designed to travel a small number of miles per day, but do so at a very low cost, whereas high mileage with somewhat higher cost per mile may be obtained from the thinner plate types. The plate frames are in all cases of the staggered type, being pressed of lead to which a small trace of antimony has been added to increase its hardness and strength. The positive plate is filled with peroxide of lead and the negative with paste lead which is substantially the general practice with lead batteries. Wooden and rubber-veneer separators are used to keep the positive and negative plates from contacting with one another and to afford definite spaces for the acid between the plates. The company furnishes the batteries with either high or low bridges on which the plates rest, but it advocates the use of a high bridge so as to prevent short circuiting of the cells by an accumulation of dead matter between the bottom parts of the cells. The covers are sealed and a soft rubber vent affords a means for flushing the battery and refilling the water evaporated and decomposed in service. If a sufficiently high bridge is used flushing of the battery does not become necessary at any time. No specific improvements have been announced so far.

Five types of vehicle-propulsion batteries are the offering of the Gould Storage Battery Company, New York City, for 1913. Two of these types use thin plates and are designed for high capacity, whereas two others are styled medium-capacity types and use thick plates; the fifth type is named semi-high capacity. Type TH or the high-capacity, thin-plate type comes in eleven sizes, fitted with 9 to 29 plates, respectively, and ranging in capacity from 110 to 385 ampere-hours. If discharged in the course of 5.5 hours, the amperage obtained from these batteries varies from 20 to 70 amperes. The other high-capacity, thin-plate type has plates considerably smaller than the type TH. This small-plate type is named NH and comes in five sizes, from seven to fifteen plates, and capacities from 68 to 158 ampere-hours. The amperage varies from 13.5 to 31.5 for a 5-hour discharge rate. The larger medium-capacity, thick-plate type is known as RP and is furnished in eight sizes having from 7 to 21 plates and capacities ranging from 84 to 280 ampere-hours. This battery is designed for 4-hour charge and discharge the current obtainable varying from 21 to 70 amperes for the eight sizes of battery. The fourth type of battery is a smaller medium-capacity, thick-plate design and comes in four sizes having from 5 to 11 plates. The ampere-hour capacities of these sizes are 48, 72, 96 and 120, and if discharged in 4 hours these batteries furnish currents of 12, 18, 24 and 30 amperes. The last type MC is referred to as a semi-high capacity design and its nine models have from 9 to 25 plates with total capacities of the batteries from 112 to 336 amperes. This type is designed for a discharge rate of 5 hours and a current obtained under this condition ranges from 22.4 to 67.2 amperes. The positive as well as negative plates in all Gould types are of a staggered design and are spaced by wooden separators which bear against the faces of the negative plates and by perforated hard-rubber sheets contacting with both sides of the positive plates. The wooden separators are formed with projections as in the case of the foregoing makes of batteries and for the same purpose. The jar is of hard rubber and fitted with a soft rubber vent permitting hydrogen and oxygen which are formed during the operation of the battery to escape.

Willard Plates Differ in Thickness

The 1913 products of the Willard Storage Battery Company, Cleveland, O., include two sizes of plates, each of which is made in three degrees of thickness: J and K correspond in thickness to the Exide plate, L and M to the Hycap Exide and N and O to the Thin Exide type, the second plate mentioned being the larger size. The capacities vary from 120 to 250 ampere-hours. Staggered grids with more but thinner bars than found in other batteries are used, the active material is practically the same as in other makes and the separator scheme roughly identical with others. Bass wood cellulose and perforated rubber form the separating materials. Standard high bridges are used to prevent short-circuiting.

Digest of the Leading Foreign Journals

Petit Shows How Considerable Aid in the Designing of a Water-Cooling System May Be Obtained from a Theoretical Study of the Temperatures Involved—An Interesting Motor Booster—Advance View of Panhard New Carbureter

THEORY of the Water-Cooling of Gasoline Motors.—With a view to the problems which arise for designers when motors must be built just large enough for the work required of them (when the motors, in other words, are to be operated a large part of the time up to their full capacity while the vehicle runs slowly), Henri Petit presents the theoretical considerations which should be guiding in the planning of the water-cooling system for such motors, the results in each case being subject to correction, of course, as practical experiments and testing may dictate. [An account of a searching practical testing method was given in THE AUTOMOBILE of last week. The practical value of the following exposition lies perhaps mainly in the fact that it compels the reader to reason exhaustively and with precision on a subject which is usually treated experimentally or imitatively only. The author shows at least that all factors involved are within reach through the science of physics. A still more substantial value can probably be realized by working it over in English terms and accompanied by an analysis of Fourier's and Ser's formulas or equivalents for the same. It might perhaps be found that the factor lambda (λ) should represent something more than the mere linear speed of the water circulation, if not exactly the pump capacity.—ED.]

According to Fourier's theory of conductivity, the heat transmitted through the cylinder wall is determined by the equation:

$$(1) \qquad q_1 = Ks\frac{V_o - V_1}{e}$$

in which q_1 is the heat transmitted; V_o the temperature of the internal wall of the cylinder; V_1 the temperature of the external wall; V_2 the temperature of the water; s the area of the internal wall; e the thickness of the wall; and K the coefficient of absolute conductivity of the material of the cylinder. The units chosen are centimeter, second and degree C. For iron at a temperature of 100 deg. C. the value of K was found by Forbes to be 0.156 which may be abbreviated to 0.15, this giving a margin of safety for the assumption that the coefficient is the same for cast iron.

The heat transmitted to the water from the wall in contact with the water must be:

$$(2) \qquad q_2 = \lambda s_1 (V_1 - V_2)$$

in which lambda (λ) is a coefficient varying with the speed of the water circulation, and s_1 the area of the external cylinder wall (inside of the jacket).

But as all the heat, q_1, transmitted through the wall is evidently transmitted to the water, q_1 must equal q_2, and we have:

$$V_o - V_1 = \frac{eq_1}{K_s} \text{ and } V_1 - V_2 = \frac{q_1}{\lambda s_1}$$

By addition of these equations one gets:

$$V_o - V_2 = q_1\left(\frac{e}{K_s} + \frac{1}{\lambda s_1}\right)$$

and as s_1 can be taken as equal to s without appreciable error, this can be simplified and written:

$$(3) \qquad V_o - V_2 = \frac{q_1}{s}\left(\frac{e}{K} + \frac{1}{\lambda}\right)$$

On the other hand, the speed of the water in the jacket is given by the formula

$$V = \frac{n}{S}$$

in which V is the speed in centimeters per second; n the delivery of the pump in cubic centimeters per second, and S the cross-sectional area of the water jacket. The water which is carried into the jacket at the temperature tau-$_o$ (τ_o) and is raised to the temperature of tau-$_1$ (τ_1) while there, takes away in one second a number of calories equal to

$$n(\tau_1 - \tau_2).$$

On the other hand it is also known that the number of calories ceded to the water is expressed in the formula:

$$(4) \qquad q_1 = \frac{s(V_o - V_2)}{\frac{e}{K} + \frac{1}{\lambda}},$$

which is derived from equation (3). The temperature of the water in the jacket may be taken as the mean between the temperatures at entering and at leaving the jacket; hence

$$V_2 = \frac{\tau_1 + \tau_o}{2}$$

And from this we get the equation which expresses a condition which can be maintained constant:

$$(5) \qquad n(\tau_1 - \tau_o) = \frac{s\left(V_o - \frac{\tau_1 + \tau_o}{2}\right)}{\frac{e}{K} + \frac{1}{\lambda}}$$

This equation cannot be solved with reference to the value of n, because λ and τ_o are both functions of n, (τ_o depending on the speed of the water in the radiator), but n can be determined from it by a series of approximations, trial values being put into the equation—which is considerably more time-saving and less costly than building trial values into the cooling system.

The cooling in the radiator.—Having established a condition under which the water when it has entered at the temperature of τ_o always departs from the jacket at the temperature of τ_1 and enters again at τ_o, we know that this water while it is away from the jacket gives up $n(\tau_1 - \tau_o)$ calories, the same number which it absorbed from the cylinders.

Let sigma (Σ) be the ventilated surface of the radiator and v the speed of the air in passing through the radiator, and let theta-$_o$ (Θ_o) and theta-$_1$ (Θ_1) be the temperatures of the air entering and of that leaving the radiator. According to the tests of Mr. Ser the heat Q given up by the hot water to the air should have the value:

$$Q = \Sigma f \sqrt{v}\,(\tau_m - \Theta_m)$$

in which τ_m is taken as the mean of τ_1 and τ_o and Θ_m as the mean of Θ_1 and Θ_o. In this equation f is a coefficient which according to Ser should take the value of 0.19403 when v varies from 67 centimeters to 461 centimeters and when $(\tau_m - \Theta_m)$ varies from 65 deg. C. to 75 deg. C. If $(\tau_m - \Theta_m)$ varies from 35 deg. C. to 45 deg. C., f equals 0.17678.

In practice τ_m is usually 70 deg. C. and Θ_m is 20 deg. C., and we can therefore take the value of f as about 0.1800.

Ser's formula can then be written:

(6) $$n(\tau_1 - \tau_0) = 0.18\sqrt{v} \times (\tau_m - \Theta_m)\,\Sigma,$$

but according to Ser's data this equation is justified only if the temperature of the air is raised about 50 deg. C in passing through the radiator. A condition of this nature should be effected. To this end, let omega (ω) be the cross-section area of the air passage in the radiator. There will then pass in each second $v\omega$ cubic centimeters of air and this air will weigh:

$$\frac{v\omega a}{1 + \dfrac{\Theta_0}{273}}$$

By ignoring the fraction Θ_0 divided by 273, we have then for the heat absorbed in the air: $v\omega a \times \gamma(\Theta_1 - \Theta_0)$, in which gamma ($\gamma$) is the specific heat of the air, or 0.237, and by accepting alpha (a) as equalling 1.293, as the textbooks have it, the quantity of heat absorbed can be written: $0.342 \times v\omega(\Theta_1 - \Theta_0)$ and from this we get:

(7) $$n(\tau_1 - \tau_0) = 0.342\, v\omega(\Theta_1 - \Theta_0).$$

And by combining with equation (5):

(8) $$0.342\, v\omega(\Theta_1 - \Theta_0) = s\,\frac{\left(V_0 - \dfrac{\tau_1 + \tau_0}{2}\right)}{\dfrac{e}{K} + \dfrac{1}{\lambda}}$$

while also keeping in mind the relation derived from equations (6) and (7):

$$f\,\Sigma(\tau_m - \Theta_m) = 0.342\sqrt{v} \times \omega(\Theta_1 - \Theta_0)$$

which can now be put in the form:

$$\frac{\Sigma}{\omega} = \frac{0.342\sqrt{v}\,(\Theta_1 - \Theta_0)}{f\left(\tau_m - \dfrac{\Theta_1 + \Theta_0}{2}\right)}$$

This equation permits us to follow the variations of $(\Theta_1 - \Theta_0)$ when $(\Sigma + \omega)$ varies.

Equation (8) shows plainly that the cooling takes place solely by virtue of the amount of air brought into contact with the radiator surface. The quantity of water, which is the intermediary agent, enters in the formula only by the variable λ which expresses its speed.

By testing the formulas in practice the following values for λ according to variations in the speed of the water are found:

Speed of the Water in Meters per Second	Value of λ	Speed of the Water in Meters per Second	Value of λ
0.10	4.2	0.60	10.
0.15	5.8	0.70	10.7
0.20	7.	0.80	11.25
0.30	8.2	0.90	12.
0.40	8.8	1.00	12.6
0.50	9.4	1.10	13.3

Cooling by the Thermo-Siphon System—Circulation of the cooling-water is frequently of late, in small motors, effected by utilizing the difference in the density of hot and cold water on the plan illustrated in Fig. 1. The reservoir A is in communication on one side with the motor M and on the other with the radiator R. A collector G is placed below the latter. It is necessary to have the reservoir at a higher level than the motor. The water heated by the cylinder walls rises into the reservoir, and the cooled water in the collector is driven by the pressure upon it into the lower portions of the water jackets.

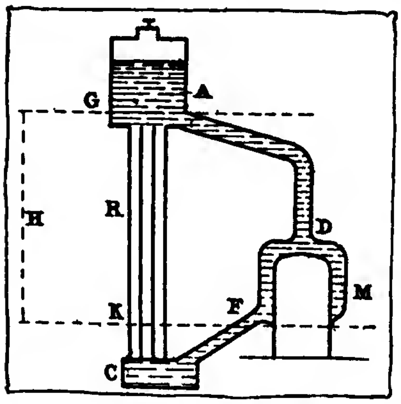

Fig. 1—Diagram of thermo-siphon system of water-cooling

Let H be the difference in levels between the reservoir and the entrances to the jackets. It may now be supposed that th water in the channel FDG is at one temperature t and that the rest of it, filling the portion GRKCF, is at the temperature t'.

The pressure per unit of surface which pushes the fluid in its direction of motion is equal to H $(\omega_t' - \omega_t)$; ω_t and ω_t' being the specific gravity of the water at the two different temperatures.

Utilizing the formula for the expansion of water volumes V_0 and V_1, according to which

$$V_1 - V_0 = (at + bt^2 + ct^3)\,V_0$$

a value for ω_t is obtained by determining V_0 divided by V_t, giving

$$\omega_t = \frac{1}{1 + at + bt^2 + ct^3}$$

in which the coefficients a, b and c have different values according to the limits between which the temperature varies.

Let it be supposed that the temperature in the collector C is lower than 50 deg. and that in the jacket it is close to 100 deg. The established coefficients give then:

$$\omega_t = \frac{1}{1 + 0.00004788t + 0.0000054628t^2 + 0.0000000175t^3}$$

and

$$\omega_t = \frac{1}{1 - 0.000063230t + 0.0000077385t^2 - 0.0000000363 75t^3}$$

By inserting the values of 90 degrees for t and 40 degrees for t', these equations give:

$$\omega_t = \frac{1}{1 + 9 \times 0.00004788 + 81 \times 0.00054628 + 729 \times 0.0000175}$$

and

$$\omega_t' = \frac{1}{1 - 4 \times 0.0006322 + 16 \times 0.00077385 - 64 \times 0.000036375}$$

and, by finishing the figuring:

$$\omega_t' - \omega_t = 0.023$$

For a height of one-half meter for H the pressure should thus be only 1.15 grams per square centimeter, equal to a head of a little more than one centimeter of water.

This pressure, it will be noticed, is very small and is in all cases proportionate to the height of H.

It is therefore necessary, if it is desired to cool by the thermo-siphon system, (1) to raise the reservoir and the radiator and to lower the motor, in order to make H as large as possible, (2) to make the water pipes of very large section, in order to maintain a sufficient speed in the water jacket and (3) to avoid all sudden turns in the piping as well as all contractions which would cause harmful friction in the system.

[Of which the moral is that the thermo-siphon system is not well adapted for large long-stroke motors.—ED.]—From *La Technique Automobile*, August 15.

COMPRESSED-AIR Motor Booster—By trials over two kilometers of a road near Paris it was demonstrated last summer that a car which could be driven at a speed of 39.6 kilometers per hour when equipped with an ordinary carbureter could reach a speed of 54 kilometers when equipped with the *Décupli* which is a device comprising a double carbureter, an air pump and a mechanism by which the air pump can be engaged and disengaged. When the air pump is working, it sends compressed air through the closed carbureter at such a rate that the motor cylinders filled up with air and fuel vapor at about twice as high a pressure as ordinarily. The fuel under this condition is fed from a special nozzle and, to make it flow, the float chamber is connected with the compressed air in the carbureter instead of with the atmosphere.

The two-cylinder air pump mechanism is operated by pulleys and belt, the power being taken from the transmission shaft of the vehicle, and the air is piped to the carbureter. This part presents no features of unusual interest, though the use of the same pump for the inflation of tires and the starting of the motor (by adding an air tank) is suggested. A section through the carbureter portion of the *Décupli* is shown in Fig. 2, and the float chamber may be imagined as located adjacently to the space between the two nozzles A and B. In this illustration G is the throttle which is connected by rod *g* with the air valve F in such manner that when G is closed F is open and supplies the air for running slowly and for starting, but when the compressed air mechanism is in action F affords an exit for the surplus air which enters at H, this arrangement admitting of operating the throttle even without first disengaging the booster device. L is the induction pipe joint, and A the nozzle for normal operation. B is the nozzle for operation with the booster in action; it is held closed by means of piston *b* until the air pressure becomes sufficient to raise this piston against the resistance of the spring which holds it against the nozzle. C is a valve letting air in at J unless it is held closed by a higher interior pressure. D is a similar valve fitted with a stronger spring and admitting additional air at K when the motor is running at high speed, but is also inoperative when the booster device is at work. E is a safety valve limiting the air pressure to the maximum desired.

The road tests of the device were timed by the official timers of the Automobile Club of France, and the laboratory trials were supervised at the Institute for Arts and Trades. A fifty per cent. increase of the motor power was uniformly demonstrated. The device is looked upon as a "reserve horse" to be used in emergencies in connection with small motors of otherwise insufficient power and has also been mentioned as a means for enabling vehicles to compete in racing events with other vehicles equipped with motors of larger cylinder volume. It is not stated whether it has been used for experimenting with other fuels than gasoline, for which purpose it apparently might be adapted. The inventors are Crouan and Huillier, 15 *bis* Rue Saint Didier, Paris.—From *Omnia*, Dec. 7.

CARBURETER in New 10-HP. Panhard.—The resemblance of the carbureter in the new small Panhard cars with poppet valve motor to the Zenith carbureter is only superficial. When the throttle, R in the accompanying illustration, Fig. 2, is closed or approximately closed the groove Y in the wall of the throttle chamber is laid open and allows the suction from the motor to act upon the secondary jet MJ instead of the main jet G, but there is established a play of interaction between these two jets which is not found in other carbureters. When the throttle is opened a little and the suction begins to act on the main jet G the gasoline feed to the secondary jet is thereby cut down, and when the opening up of the throttle continues the secondary jet runs dry and begins to feed air backwards into the interior of the main jet, acting as auxiliary air duct. The air, managed in this way, assists in atomizing the spray while also reducing the richness of the mixture. The proportions of the mixture are regulated by means of a second auxiliary jet F at the base of the main jet. It is by means of F that the gasoline, which enters from the float chamber through the channel U, is fed downward to jet MJ when the latter is in action. V is the screw for adjusting the channel YM to the slow-speed jet M. E is the air intake.—From *Omnia*, December 14.

[The description does not reveal the exact manner in which the jet F operates or how the air is introduced which finds its way from jet MJ to the interior of jet G—unless it be taken directly from the induction channel. Neither does the illustration give any clue on this point, unless the lateral openings shown at T in MJ may be taken as an indication in this respect. The idea of mixing air with the fuel in the interior of the jet has been tried in other carbureters and seems to be gaining ground.—ED.]

INVENTOR of Gas-Accumulator Honored.—The Nobel Prize for physics was awarded this year to Gustav Dalen, a practical Swedish engineer, who unfortunately lost his eyesight by a gas explosion in September, 1911. He invented modifications in gas-accumulator systems which have resulted in the development of the acetylene gas tanks used as a light-source in automobiles, and also for buoys and lighthouses which give intermittent flashes during the night and in murky or foggy weather. These are in use along the entire coast of South America and along the Panama Canal. His acetylene gas-accumulator consists of a steel receiver filled with a porous substance prepared with asbestos and soaked with acetone. This forms a mass of capillary cells which prevent the acetylene molecules from being pressed hard together and thereby obviate an otherwise possible explosion. The Dalen gas-accumulator can absorb gas to the extent of a hundred times its own volume.

When these tanks are used for buoys or lighthouses they are equipped with a sun-valve, also invented by Dalen, which shuts off the gas when the sun is shining and turns it on and lights it when darkness sets in for any cause. These buoys therefore require no attendance except for renewal of the gas supply. The sun-valve operates by the unequal expansion of two bars of different metals, one black, so as to heat up in the sunshine, and the other bright.—From *Engineering*, Dec. 6.

Strength of River Joints.—An article on tests of nickel-steel riveted joints, based upon tests made with rivets and plates of different alloys—as well as plain carbon steel—at the University of Illinois, is found in *Engineering* (London) of Sept. 6.

The Engineers' Forum

combustion chamber of the cylinder. The greater the rush from the fuel nozzle, the more thorough the breaking and scattering of the fuel.

A Theory of Carburetion

Forrest A. Heath Considers Complete Breaking Up of Fuel Particles Into Small Globules Most Important

NEW YORK CITY—Editor THE AUTOMOBILE—The interest you are stirring up in the carburetion problem is very valuable. There is no department of hydrocarbon engineering so little understood and so greatly in need of illumination.

What the engineer wants is a simple mechanism that will furnish the required amounts of fuel and air, carburet the air with fuel, and supply the resulting mixture in varying volume **without variation as to its combustibility.**

A lump of coal burns slowly until consumed. Gasoline burns in the same manner. The lump of coal, broken into small pieces, burns more rapidly. The gasoline, separated into drops, acts similarly. Coal, converted into powder and scattered through the air, will exhibit the explosive characteristics of gasoline vapor. Gasoline vapor is composed of minute particles scattered through the air. In each case the fuel, when converted from the lump into the powder, changes its state of aggregation. The change makes it possible for more of the oxygen of the air to come in contact with more of the carbon and hydrogen of the fuel.

The axiom that the actual power of a hydrocarbon motor depends upon the speed with which the fuel burns, means that the more rapid the expansion of the gases, the greater the duration and extent of the pressure on the piston.

In the operation of a motor the gasoline is drawn from the carbureter float chamber through a nozzle, where it comes in contact with a current of air which carries it to the combustion chamber of the cylinder. The greater the rush from the fuel nozzle, the more thorough the breaking and scattering of the fuel.

Each suction impulse starts a spurt of spray from the nozzle. Instead of a column of homogeneous mist there is a column of air carrying intermittent jets of fuel, and at high piston speeds a stream of gasoline spray. The column of air, with its entrained spurts of gasoline streaking through it in parabolic curves, is drawn first to one cylinder, then to another. The inlet valves are opening and closing in accordance with the speed of the motor, but without regard to the time of arrival of the fuel spurts. Except at very high piston speeds the mixture distributed to the cylinders is of varying density.

Fig. 1 shows a jet of fuel from a carbureter nozzle under low vacuum. Fig. 2 shows the changed condition of the fuel under high vacuum.

Fig. 3 is a magnified representation of a fuel particle from Fig. 1. Fig. 4 represents the particle broken up into eight smaller globules, as in Fig. 2. While the mass is the same in both cases, the surface area exposed to the heat of the air for evaporation, or to the oxygen of the air for combustion, is twice as great in Fig. 4 as in Fig. 3. Evaporation may be said to be the result of attraction exerted by the heat of the air upon the surface of the fuel globules, drawing minute particles away from the mass. A B and A' B' represent equal sections of fuel surface, as shown by X and Y, upon which equal attraction is exerted. But molecular attraction within the mass of the Fig. 3 globule is twice as great as that of the Fig. 4 globule, as shown by the cone surface areas A O B and A' O' B'. Hence, the 100 per cent. advantage in evaporation surface possessed by the Fig. 4 globule is augmented by 50 per cent. less resistance to evaporation. Therefore, in the condition represented by Fig. 4 only one-half as much fuel is required for combustion as in Fig. 3, the amount of air being constant. And, moreover, as the waste is greater in the case of Fig. 3, because of the greater quantity of carbon coking out under the heat of compression, the saving of 50 per cent. in fuel is accompanied by an increase in power.

With the carbureter adjusted properly for speed, the motor will not pull a full load satisfactorily when running slowly. In the latter case the fuel is not only less combustible, as shown above, but the air is carbureted in splotches. Therefore the walls of the carbureter, intake pipe and manifold must be drenched with an excess of fuel to provide additional vapor to fill up the uncarbureted zones.

What is required is **a thorough breaking up of the fuel and an intimate mixing with the air and a means of maintaining constancy in this operation under varying vacua.**—FORREST A. HEATH, The Aristos Company.

Criticisms of Non-Poppet Valves To-Date

Rotary Valve Type as Yet Comparatively Undeveloped, This Group in the Non-Poppet Class Presenting An Extensive Field for the Designers—Excellent Results May Be Expected From Future Research

By Eugene P. Batzell Installment III

THE English valve construction, Fig. 13, is not the only one using the interior of the valve for the combustion chamber. Everything stated in regard to the foregoing valve type applies in a still greater degree to this design. The inside of the valve communicates with the cylinder through ports C and with the inlet or exhaust passages by means of a port D for each cylinder. In the state as represented by Fig. 13 this type of valve should be condemned as entirely inoperative, but energetic shell cooling would improve it.

Though this criticism is impartial, I regret my inability to indicate notable merits in the criticised rotary-valve systems and my standpoint in this respect has been confirmed by the practical experience with those few systems which have been actually built and tried. None of them has yet shown convincing proof of its superiority over other systems and of its reliable functioning. Here is meant a functioning satisfactory to the would-be customer. **This branch of non-poppet valve motors is still in its infancy and subject to much research and development work, but there is a reasonable prospect of good results being achieved.**

Concluding the discussion concerning rotary-valve systems, I wish to draw attention to a combination which has received very little consideration thus far, but which may have future value, namely, external air cooling of the barrel-type valve seats, omitting water cooling entirely. The requirements of proper valve operation are chiefly the permanency of clearance and valve shape, and as exterior air cooling would leave the temperature of the valve seat nearer to the temperature of the valve proper less change in their clearance would result. In addition the valve could be preserved from distortion by using a proper design and annealing it thoroughly, as well as annealing the cylinders. Lubrication

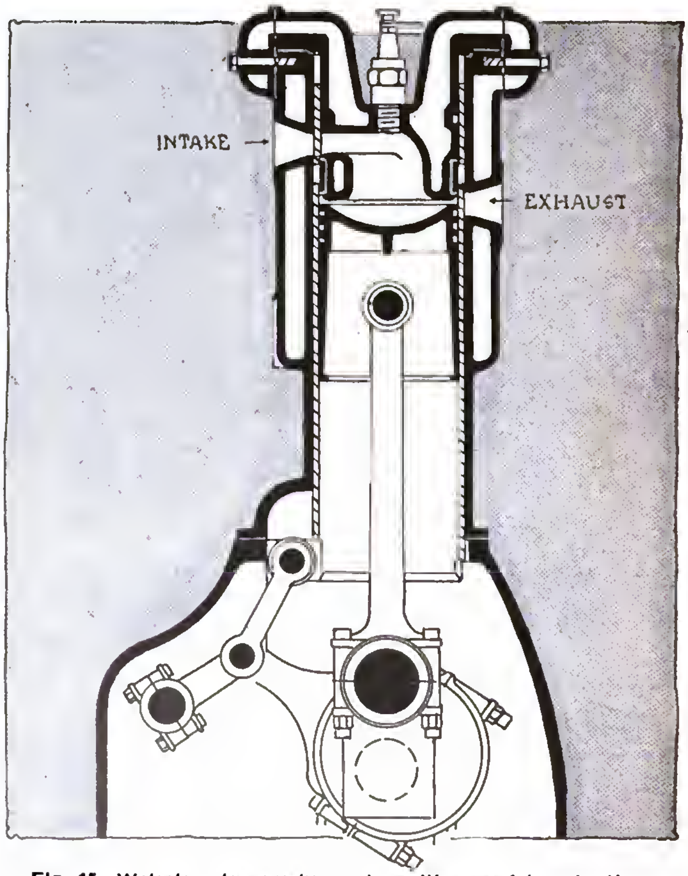

Fig. 15—Wolseley sleeve-valve motor with eccentric actuating mechanism

should not be very difficult because some oils can stand higher temperatures than would be possible in the valve seat.

If the rotary valve has been popular with individual inventors, the reciprocating-sleeve valve has received the attention of quite a number of established automobile manufacturers. Generally this valve gear is more complicated in construction and manufacturing than the rotary type, but the success which has followed the Knight motor and also the experience gained through its use explains this attitude of the manufacturers. In their patents and constructions these other sleeve-valve designers have aimed at more simplicity than the double-sleeve Knight motor offers, and in consequence of this as well as for avoiding interference with the Knight patents, the single-sleeve valve motor predominates in the latest patent issues. It is significant that years ago, at the time of the first rumors of the achievement with the Knight motor, various sleeve-valve patents were taken out covering many kinds of arrangements with two sleeves, differing from the Knight construction in the manner of actuating mechanism and motor cooling, whereas the single-sleeve variety received attention later. To obtain the necessary motor timing with a single reciprocating-sleeve valve the latter must have an irregular motion, and at present this is chiefly obtained by means of a link mechanism with two eccentrics or with one eccentric and one fixed point. Examples representing the above are the Wolseley motor, Fig. 15, for the first and the A. E. G. (German-General Electric Company), Fig. 16, for the second type of link motion. Other characteristic single-sleeve motions are found in the Argyll, Fig. 17, and the Diehl, Fig. 18.

The Rolland-Pilain, Fig. 14, and the Wolseley are very much alike as to the nature and construction of the valve mechanism and some advantage of the second over the first motor can be seen only in the type of cylinder head construction, inasmuch as its sleeve ports are protected from the high explosion temperatures. This has always been considered a good point in the Knight system. Fig. 15 shows the Wolseley motor at the firing moment and it is self-explanatory in regard to the above statement. On the other hand, the original Rolland-Pilain construction, Fig. 14, not only keeps the sleeve ports in the combustion space continuously, but still more, it fires the charge through the intake port by passing it opposite the spark-plug, which is located in the side of the cylinder. The intake port becomes exposed to the highest temperature and also to the action of the initial flame of combustion directed from the spark-plug into the cylinder. It will be remembered that burning out of the ports was a defect sought in the Knight motor which may have caused much of the audible port whistling notwithstanding its port protection.

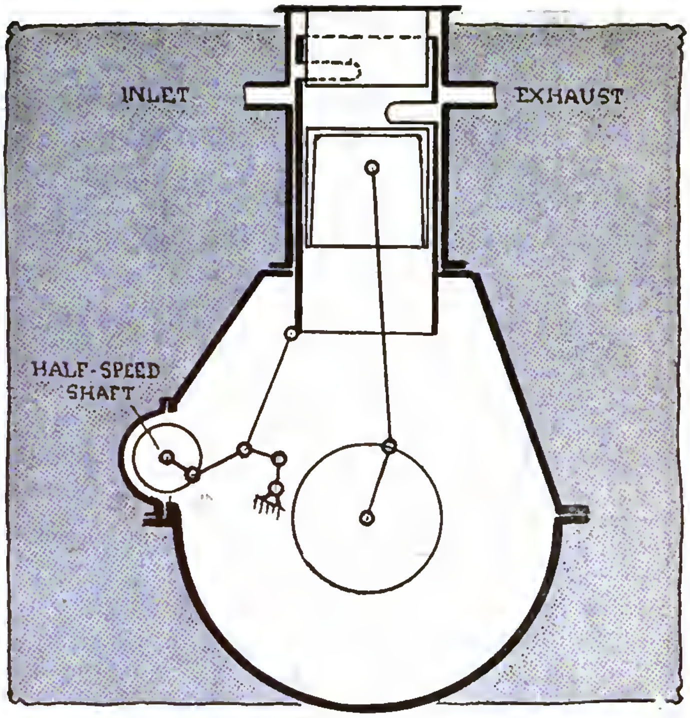

Fig. 16—A. E. G. link motion for actuating sleeve valve

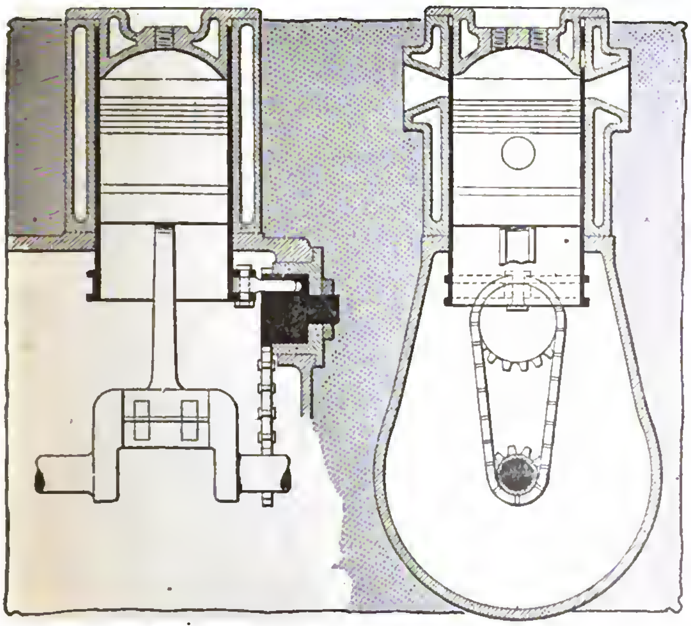

Fig. 17—Argyll single-sleeve valve motor

The A. E. G. link motion, Fig. 16, substitutes an eccentric by a fixed point, thus gaining in constructive simplicity. At the same time it affords material improvement in the shape of the valve opening interval over that of the double-sleeve scheme which has a pointed valve opening curve characteristic of the Knight motor. On the other hand, its mechanism has a number of joints in series whereby any wear will affect the valve motion considerably.

The Argyll system, Fig. 17, is an ingenious example of a combination valve motion being equivalent to a rotary motion of the valve ports in the cylindrical surface, but here again one of the sleeve ports is exposed in the combustion chamber during the explosion. If that is the inlet-port it can be covered by the piston for some duration at and near its upper dead center. It remains to be proven by practical use of this motor, how reliable its valve mechanism is, as some doubt in this respect can be freely attached to the present arrangement with its number of cantilever pin-bearing joints.

(To be continued.)

Loss of Water by Evaporation

Evaporation occurs, for the most part, where alcohol is used as an anti-freezing mixture. Where the alcohol is used in this manner it generally occupies from one-third to one-half the volume of the whole compound. It can readily be seen that this mixture will have a great tendency to be reduced very rapidly. It so happens, however, that the anti-freezing solution is only used at that time when the cooling system is in reality more efficient than is required. On account of the temperature of the air, the motor is not very apt to become overheated. The radiator is generally reduced in effective area during the season of the year that the anti-freezing solution is used, by covering it in some manner. Evaporation in the summer is the only way in which the quantity of water in the cooling system is reduced, if it is in good condition; therefore, loss of water by evaporation becomes merely a matter of watchfulness on the part of the operator.

Bad Valve Adjustment—Carbureter Formula—Painting the Ca[...]r—Explaining Rotary Valves—Soldering Cast Iron—Civil War Book Gives Roads[...] Five-Cylinder Question Again—Defining Oversize Bearing—Hup Oiling [...] System

—

Case of Adjustment Trouble

EDITOR THE AUTOMOBILE:—I have an E. M. F. car which has been causing some trouble for the last few weeks. The engine does not have very good compression. I have just ground the valves and fitted new piston rings. It will fire all right when it is running slow and pulling, but as soon as it is speeded up it will miss. It will also miss when running idle. I have changed the spark plugs, but the missing occurs as before. I have changed the air adjustment on the carbureter.

2.—Why does the small bevel gearwheel in the differential break?

Saylorsburg, Pa. READER.

—It would appear that the cause of your trouble is that the valve tappets are adjusted too tightly. In these motors the clearance has to be .006 inch at least in order to get the power. The machinist who ground your valves has probably left but .003 or .004 inch clearance, and this is insufficient in the case of the E. M. F. motor. If you have a car dated previous to 1909 there are no tappet adjustments, and your trouble is elsewhere. The only other place it could be, unless it is due to a break in the wiring concealed by the insulation, is in the carbureter. The first would cause a misfire that would appear and disappear, and which could only be found by a close examination of the wiring. The carbureter trouble is in the adjustment, which seems to give too lean a mixture. A dirty carbureter causes trouble of a recurring nature and may be remedied by giving the instrument a thorough cleaning. Drain the float chamber two or three times to remove all sediment. Poor gasoline will also cause the trouble you mention. It may be well to try another place for your fuel supply before doing anything else.

2. Because it is not in proper mesh with the large gear. This should be attended to at once by a machinist.

Correct Carbureter for 4-Inch Motor

Editor THE AUTOMOBILE:—What is the proper size carbureter for 4 by 4, four-cylinder, four-cycle motor?

New York City, N. Y. F. M. DOBBS.

—In THE AUTOMOBILE for December 26 a formula for the correct size carbureter is given. This formula is as follows:

$$\text{Size in inches} = \sqrt{\frac{D^2 \times S \times R}{C}}$$

In this formula D is the diameter of the cylinder, S the stroke, R the revolutions per minute, and C a constant which is equal to 50,000 for automobile motors of the four-cycle type. Figuring by this formula, and assuming a maximum revolution of 1600 per minute, the correct size carbureter would be 1.5 inches. The nearest size above that given by the formula should be used in every case. The diameter and stroke of the motor effect the carbureter size; the number of cylinders does not affect the size, but does affect the manifold.

Rejuvenating the Ext[...]erior

Editor THE AUTOMOBILE:—I have an auto[...]mobile that needs considerable touching up in the way of paint. [...] I cannot afford to have the work done by a carriage painter an[...]d yet I would like the car to look well. It does not require a v[...]ery thorough job, and I would like to know through THE AUTO[...]MOBILE how to go about the work myself. The body is metal.

Saratoga Springs, N. Y. J. G. K[...]

—The complete outward renovation of a car is sometim[...]es too costly an operation as outlined. Those who may desi[...]re a cheaper and quicker method can begin with the body, pres[...]umably of aluminum or some other metal, and have it gone o[...]ver with a patch of emery cloth, or emery paper, or a fine w[...]ire brush, and, in the absence of these mediums, with some coars[...]e sandpaper. Thus rid the surface of foreign substances and con[...]dition it to receive and hold the pigment applied to it.

As to the best available primer. Use, if opportunity affords, a purchased ready-to-use metal primer, to be applied with a soft point round or oval bristle brush, the coat being brushed out smooth and uniform. If shop-prepared, use 2 parts raw linseed oil and 3 parts pure turpentine, to a pint of which mixture add a teaspoonful of pale drying japan. For coloring matter and to give body to the primer add enough oil ground lead colored in the direction of the to be finally chosen color. Another primer that some painters have found to work out very strong and well upon the metal surface consists simply of elastic finishing varnish brushed out thinly over the surface.

As soon as the primer is dry, good and secure, beat up some keg lead in 1 part raw linseed oil and 6 parts turpentine, give it the proper coloring, and apply with a soft chisel point brush.

After allowing for secure drying proceed either with a ready prepared knifing material, of which there are numerous makes, or with a shop-mixed one prepared of 3 parts dry white lead and 1 part best bolted whiting, worked into a plastic glazing condition in equal parts of rubbing varnish and coach japan, letting the mass down a bit with a little pure turpentine. Apply with a broad 1-2-inch French scraping knife, half elastic, working the pigment out so uniformly smooth and fine as to necessitate little if any sandpapering.

Permit this coat of knifed-in surface to dry for 48 hours, at which time using first No. 1 sandpaper and last No. 0 to polish with, fetch the work up to a smooth, glassy condition.

Over this foundation lay a coat of color ground work, or, in other words, a coat of color to serve as the ground or foundation color. Prepare this color by using 1 part raw linseed oil to 5 parts turpentine, which, in case of a japan ground color, will furnish requisite elasticity, durability, and a ground color devoid of gloss yet not drying out to a dead appearance—the latter to be avoided at this point in the finish.

In the event of using lake pigments for the final color the next coat over this preparatory ground color should be a coat of the lake whipped in turpentine to dry flat. Then over this use the lake floated in elastic rubbing varnish. When the color is of the ordinary opaque pigment, or, at most, semi-opaque, such as, for example, ultramarine blue, wine color or carmine, make a varnish color for the opaque pigments, consisting of 1-4 pound of color to 2 pounds of varnish, and for the semi-opaque or transparent pigments, following a solid ground, use 3-4 ounce of color to 1-8 gallon of varnish.

After 36 hours this varnish color, or the transparent glaze, will have dried so that it may be lightly rubbed with water and pumice stone flour to the extent of flicking away any dirt nibs, an elastic body-finishing varnish of the very best grade obtainable should be applied.

For the next coat reduce by one-half the amount of color used in the varnish and apply freely to the surface. Let this coat stand two days, at the expiration of which time again rub with water and pumice stone flour, wash up, stripe and apply such other ornamentation as may be desired. Then apply a coat of clean rubbing varnish. After three days rub this coat moderately with water and pumice stone flour, wash up and finish with an elastic body-finishing varnish of the very best grade obtainable.

Bring the chassis meantime along practically the same lines, using one coat of primer, then a coat of surfacing pigment containing enough raw linseed oil to insure adequate elasticity, upon which foundation use the knifing putty to level up the inequalities of the surface and to "face up" any other existing defects. Sandpaper this body of pigment down sleek and smooth, after which apply one coat of flat color, then one coat of transparent glaze or one coat of varnish color as the requirements of the work may indicate, upon which, in due time, after breaking down the gloss with a light rub-over with a soft sponge, moist and saturated with pumice stone flour, stripe, and apply one coat of clean rubbing varnish.

Give this coat plenty of time to dry, three days or more if possible, then surface thoroughly with water and pumice stone flour, wash up sleek and clean and finish with an elastic chassis finishing varnish.

Duryea Explains Rotary Motor

Editor THE AUTOMOBILE:—Your recent reply to the question of Mr. Lefler in THE AUTOMOBILE December 19, noted. Doubtless you have mixed my present production, which uses engines of the two-cycle type, with the engine which Mr. Lefler refers to. If you will look through reports of the shows 6 years ago you will find that I exhibited at the New York show of 1907 a rotary valve engine having three cylinders, 5 by 5 in a single block, and also a sectioned engine showing just the operation of this new style. I also showed a valve that had been in the hands of a customer for more than 6 months and was in perfect order. My patent on this device is about to issue and antedates other constructions of this kind. It antedates the patent application of the foreign engine mentioned by some years. It is interesting to note that the foreign patent on the engine mentioned was not applied for until some months after the New York show above mentioned.

The two valves are practically the same. In my engines the valve was far enough down the side of the cylinders to permit the piston overrunning the ports slightly, the idea being to oil the valve from the pistons. The engines built by my associates during the present year have had the valve directly on top of the cylinders and fitted with oil cups for taking care of the lubrication. This makes a very symmetric engine. It is interesting to note that I not only originated that type of valve for auto use, but was the first also to use silent chains for driving it; a clear lead of some years over the present silent chain advocates.

The rotary valve is a very sweet running device and well adapted to high speeds. It seems to me well adapted to displace the more common poppet, and the more complicated other forms.

Saginaw, Mich. CHAS. DURYEA.

Best Flux for Cast Iron

Editor THE AUTOMOBILE:—In soldering the cast iron water jacket on the cylinder of a motor what would be the best flux to use?

2. How is the piston displacement of a motor calculated? Also the radiator cooling surface?

3. What was the result of the fifth annual reliability trials of the Scottish Automobile Club in the Summer of 1909? Is it true that the cup was won by a Knight motorcar?

Detroit, Mich. C. G. WILLIAMS.

—1. A flux which can be used to solder the water jacket of a cast iron cylinder is cut muriatic acid, that is, hydrochloric acid in which zinc has been dissolved. For tinning, use four parts of salammoniac solution in water and one part of hot hydrochloric acid. The action can be improved somewhat by sprinkling a little powdered salammoniac on the surface.

2. The rule for finding the piston displacement of a motor cylinder is that of finding the cubic contents of a cylinder, which is as follows: Multiply the area of one end by the length of the cylinder, the product will be the cubic contents of the cylinder. The rule for finding the area of a circle, consists in multiplying the square of the diameter by .7854. The formula for finding piston displacement is: D^2 .7854 S N = piston displacement, in which D is the diameter of the cylinder, S length of stroke, N number of cylinders.

Therefore, to find the piston displacement of a motor with 5-inch bore, 6-inch stroke, and four cylinders, substituting the numbers for the letters of the formula, it would read: 5^2 (five square) $\times .7854 \times 6 \times 4 = 471.2$ cubic inches.

There is no formula for finding the radiator cooling surface necessary for any four-cylinder motor that is applicable to all types and makes of motors or radiators. This is because of the great variation in the cooling efficiency of the various designs of motors and radiators made. Each radiator maker, however, will be able to very closely approximate the amount of surface of its own design most suitable for any particular motor.

3. In the fifth annual reliability trials, held in the summer of 1909 under the auspices of the Scottish Automobile Club, there were sixty-five starters, out of which fifty-eight finished. The trials, which consisted of a combined reliability and economy test, included three hill-climbs and a brake test, lasted 6 days and

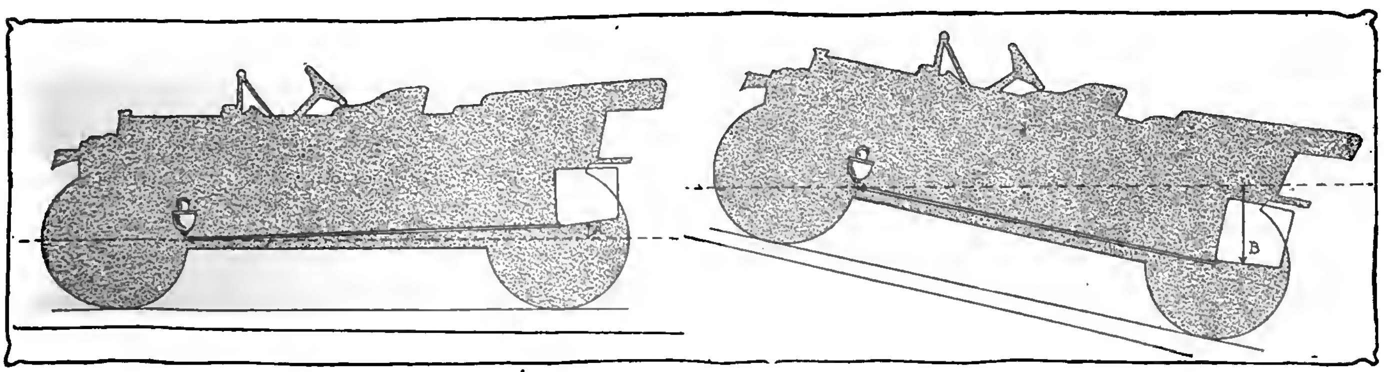

Fig. 1—Showing difference in carbureter and tank relationship when car is on level and hill

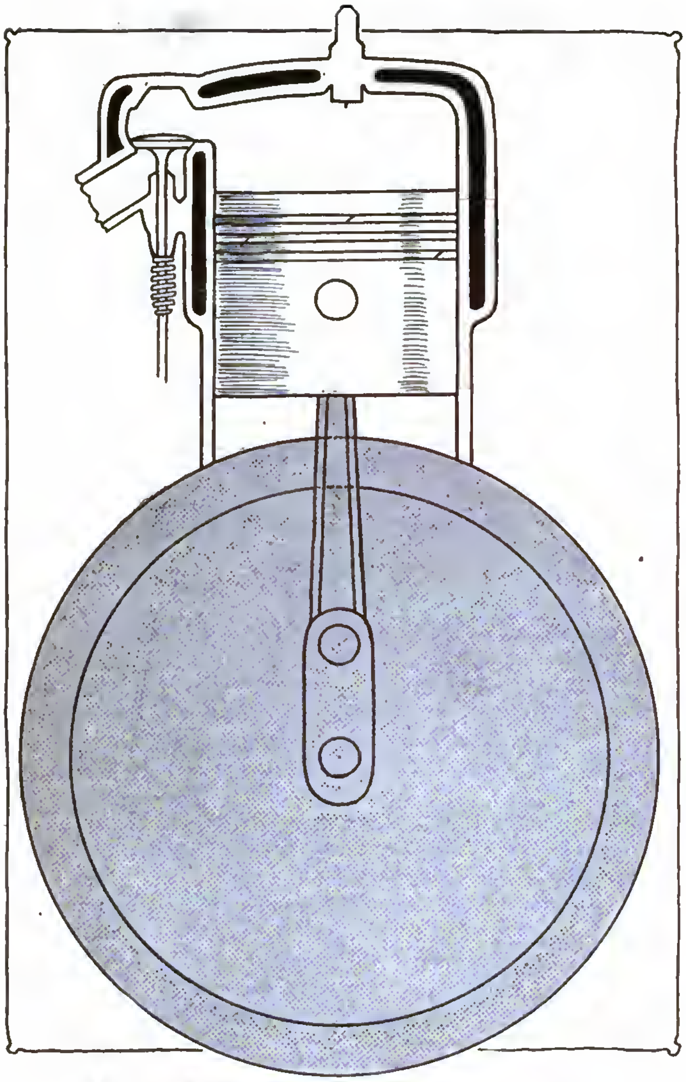

Fig. 2—Flywheel is necessary to carry piston past this point

covered a distance of over 1,007 miles, in stages averaging 170 miles per day at a scheduled speed of not less than 17 miles per hour and not more than 20 miles per hour. The entries were divided into eight classes according to price, and the winner in each class was awarded a gold medal, while bronze medals were awarded each class having the best hill-climbing results. The Scottish cup was awarded to a 38-horsepower Minerva car equipped with a Knight engine. This car also received a bronze medal. No official tests of the Knight motor in its present stage of development are recorded.

Finds Routes in Old Book

Editor THE AUTOMOBILE:—Four or five years ago, when I was devoting considerable time to the laying out of touring routes in the Southern States, I had practically no data at all to use as a basis in laying out my trips. At that time I could not procure anywhere any maps of the Southern States which showed the location of the main roads, and in planning my trips I had to rely on ordinary maps, and to take it for granted that where I saw a number of towns in a line, that there would be a highroad connecting these towns.

In other cases, as, for example, in seeking a road from Macon, Georgia, to Savannah, I simply noted on an ordinary map the general course of the rivers and streams, and laid out a road along what I considered would be high and dry land, and where, as later proved to be the case, there would most likely be found the most "navigable" road.

Recently I ran across a book which contains the best and most complete road maps of the Southern States I have ever seen, and, had I had this work before me when I was touring in the Southern States, I would have saved myself a tremendous amount of miscellaneous investigation, and also a great deal of guesswork.

Nevertheless, to those who wish to cover routes which are not yet included in the Blue Book, I wish to recommend my recent topographical "find." The book I have reference to is "The Rise and Fall of the Southern Confederacy," by Jefferson Davis, published in two volumes, by Appleton & Company in 1881.

In the back of the second volume of this work will be found very accurate and well printed maps which give the exact location of every important highway which existed at the time of the Civil War.

It is almost unnecessary to state that the older a road is, the more likely it is to be the most important in any given locality, for reasons which every tourist will appreciate.

The books referred to above are now out of print, and I have found it impossible to procure a set for my own library, although I have had two of our most important booksellers on the lookout for copies. The books may be found, however, in all the important public libraries, and the maps above referred to are well worth the inspection of every one who is interested in touring in the Southern States.

New York City. R. H. JOHNSTON.

More on Five-Cylinder Motors

Editor THE AUTOMOBILE:—It is very evident that I failed to make myself clear in a previous article on five-cylinder motors, and I would like to have it understood that I did not intend to convey the meaning that such motors were not successful. In my comparison of five and six-cylinder motors (which was based on facts and not on my opinion), I picked out the advantages of one over the other in their most important points, and although I found the former a successful motor and just as superior to a lesser number of cylinders as one would expect, I take exception to any statement that puts it on an equal with the six. One cannot fairly take into consideration the consumption of fuel and oil, in these two motors when comparing their superior qualities for motor car propulsion. If so we would have to admit the single cylinder as the most successful.

In the issue of THE AUTOMOBILE of November 28 I gave an illustration of motors operating without flywheels, and I did this for the purpose of showing that only theoretically do five cylinders produce a constant torque. A motor that requires a balance wheel to carry it over certain dead or slack portions does not produce a practical constant torque. In this motor (five-cylinder) the explosions overlap each other to the extent of 36 degrees, and as the actual working stroke of a gasoline motor starts not sooner than 10 degrees past top center and ends not later than 150 degrees, it shows an interval of 6 degrees when no power is being generated. Some manufacturers confine this working stroke to 120 degrees. In the cost of manufacturing the crankshaft of these motors there would be a difference of about one hundred dollars, the five costing that much more than the six, and it would be necessary to eliminate more than one cylinder and its parts to make up this difference.

Certain approved methods such as casting cylinders in pairs and four bearing crankshafts, would have to be abandoned for the unapproved or obsolete in order to adopt the five-cylinder motor.

In regard to the motor being lighter and allowing the hood to be shortened, I will say that the average engineer will not consider such attempts at the expense of the smooth and silent operation of the car, especially when the saving in weight would hardly be noticeable either in the life of the tires or the operation of the car.

Portland, Me. GROVER C. RICHARDS.

What Is an Oversize Bearing?

Editor THE AUTOMOBILE:—What is an oversize bearing? I should like to have you decide a question which I have argued with a friend. I had occasion to have a cut taken off a crankshaft which had been scored and stated I wanted an oversize new bearing put in. Issue was taken with me for calling it an oversize bearing, he stating that as the crank hole diameter was smaller in the new bearing and consequently its bearing surface smaller, it should be called an undersized bearing.

I maintain that as the radius center of crankshaft to outside of bearing is fixed in any particular engine the mere fact of taking a cut off the crankshaft makes it undersize and consequently the new bearing becomes oversize. In other words, you cannot fit an undersize bearing to an undersize crank when the radius center of crankshaft to outside bearing is fixed and remains so.

Cincinnati, O. A SUBSCRIBER.

—An oversized bearing on the crankshaft is one in which the fit is too loose. That is to say, the bearing with the greatest internal radius is a larger bearing. Therefore, your friend is right and you are wrong. The size of the bearing is measured by the diameter of the circle which would be formed by a section through the bearing at right angles to the axes of the shaft. You are thinking of the thickness of the bearing metal, which does not affect the size of the bearing.

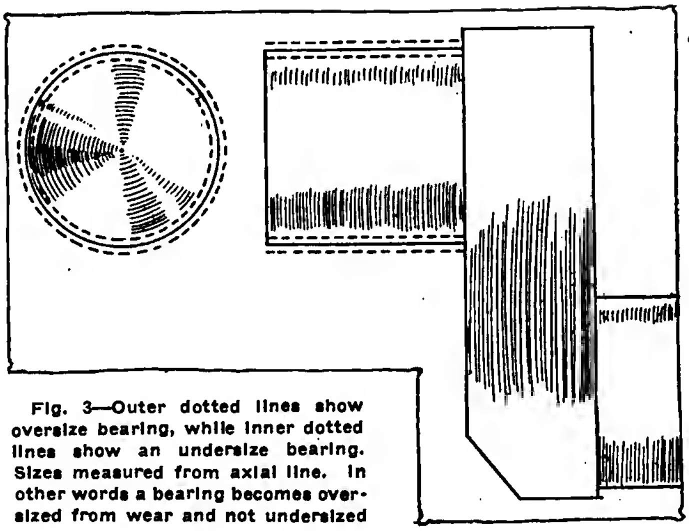

Fig. 3—Outer dotted lines show oversize bearing, while inner dotted lines show an undersize bearing. Sizes measured from axial line. In other words a bearing becomes oversized from wear and not undersized

Getting the Car Weighed

Editor THE AUTOMOBILE:—I notice in the tire tables that the different loads are given for the front and rear axles separately to determine the correct size of tire. Would you tell me how to get these weights correctly.

2. Why is it that pressure feed is used when the tank is flung at the rear? Cannot the carbureter be placed low enough for gravity?

New York City. J. E. S.

—The correct method of weighing a car given in Fig. 4.

2. In order to make the carbureter high enough to be accessible it is necessary to use pressure feed when the tank is carried at the rear. This is brought out in Fig. 1. When the car is on level ground the feed may be by gravity but while on a slope pressure would be necessary.

Oiling System on New Hup

Editor THE AUTOMOBILE:—Would you kindly tell me if the same oiling system is used in the new Hup 32 as in the Hup 20-horsepower runabout? The latter, as you will remember, used a gravity-feed system by which oil is fed to the crankcase by gravity, the amount fed being governed by a cam arrangement on the throttle control.

Denver, Col. L. C. SMYTH.

—The automatic oiler on the Hupmobile 32 makes use of a flywheel of the motor and of centrifugal force. The lower part of the crankcase and the flywheel housing are integral. The crankcase slopes downward toward the flywheel compartment, and oil runs into this lowest point which is designed as the oil pan. The flywheel rim is close to the bottom of this oil pan at its deepest part. When the flywheel revolves, some of the oil in this pan or sump through which the rim travel, adheres to the rim and is carried around with it. Half way up on the right inside of the flywheel case there is a horizontal rib which is machined to just clear the rim of the flywheel. The oil adhering to it is thrown with considerable force against this rib and into a tube which enters the housing just below the rib. The oil passes through the tube to a strainer contained in the filling tube casting. This strainer is 3 inches in diameter and is set vertically so that all grit and sediment collect at the bottom, where they may be washed out by opening a pet cock while the engine is running. From the strainer the oil passes into a 1-2-inch horizontal duct cast in the crankcase. Three 1-4-inch tubes conduct the oil under pressure of the flywheel's centrifugal force to the centers of the main bearings of the crankshaft.

Quarter-inch holes drilled in the crankshaft allow the oil to flow to the crankpin bearings. The oil spray flung from the ends of these bearings is sufficient to lubricate the cylinders under ordinary conditions, but as an additional precaution, oil leads are provided direct from the distributer pipe to the points between cylinders Nos. 1 and 2, and Nos. 3 and 4. These force oil into the hollow piston pins and fill the grooves around the pistons. The camshaft bearings are lubricated by the splash of the connecting-rod ends in the sumps at the bottom of the crankcase. Oil thrown from the flywheel toward the rear goes into the gear case and maintains the proper level for the gears. The excess oil is returned to the crankshaft, due to the sloping construction of the housing. Grit and sediment from the gears are retained in a settling basin, and may be removed by taking out the large drain plug.

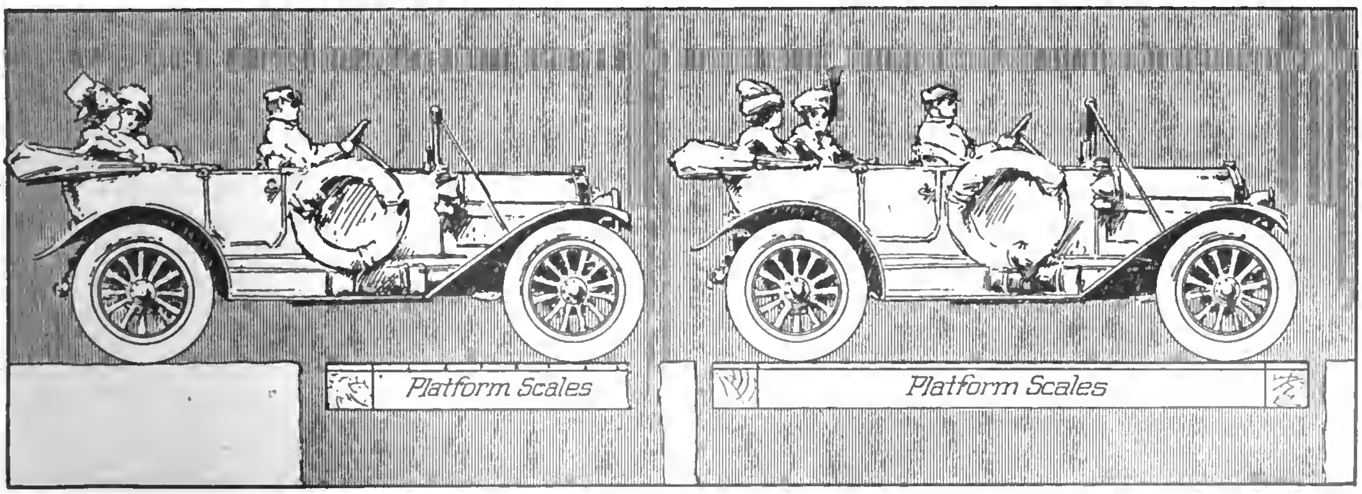

Fig. 4—Method of weighing car. First, to get load on front axle; second, total load; third, rear axle load

The Strength of Union

IS it better for both passenger and commercial electric vehicle makers to stand aloof from gasoline makers of passenger and commercial vehicles, or to work hand in hand with them?

There is only one answer to this question, namely, "Get together, it is the motor-vehicle-against-the-horse problem that has to be solved and not whether it shall be electric or gasoline vehicles."

Makers of electric passenger vehicles recognize that they cannot compete with the gasoline passenger vehicle except in city and intercity work where the distances are not too great. Makers of gasoline passenger vehicles recognize in the electric passenger car a vehicle of general utility for such services; and they further recognize the extent to which the closed type of electric supplements the open type gasoline vehicle, where the two are in the hands of the same owner, one for fine-weather country or city use and the other for all-weather city and suburban service.

Makers of electric commercial vehicles recognize the limitations of their vehicle as compared with the gasoline type for long-distance work; and on the other side of the fence the gasoline maker gives due heed to the ideal adaptation of the electric for city use with short-distance hauls and the varied conditions of traffic congestion.

What is the net result? Get together. Combat the common enemy. Work hand in hand for better traffic control; for improved city railway and steamboat terminals; for necessary renovation of internal systems in business houses which will reduce lost time in loading or unloading; and work for the rational education of the buyer.

Beyond the Horizon

WHEN will the day come when the owner of an electric passenger vehicle can start from his New England home and tour to Denver, Col., without more loss of time than required to remove the discharged battery at convenient charging stations along the road anad install a full-charged one?

When that day arrives the electric passenger and electric commercial vehicles will have attained their maturity.

Such a conception of affairs is not entirely utopian. There are many fibers of rationalism in its warp and woof. It presupposes very considerable progress. It can only be achieved when batteries and other parts have been well standardized. It can only be achieved when central stations or other interests have installed charging plants at intervals of 75 to 100 miles distance from one another over the country; it can only be attained when batteries are owned and controlled by some combination of the central station and battery-manufacturing or other interests; and it can only be attained after the adoption of some general plan whereby the purchaser of a vehicle buys it without a battery and when using two dozen different batteries between Boston and Denver pays in addition to the cost of current a rental for the use of the different batteries.

A looked-for condition of this nature is in the minds of nearly every maker of electric vehicles. True, the conception is embryonic, vague, undefined; but in every case the feeling is one of certainty as to its eventual evolution. The question of battery ownership is the major element calling for solution.

If battery ownership rests with the owner and he or she starts with a new battery from Boston he or she has it but for a single day, and may never see it again on the 2,000-mile trip. Instead of a new battery every day he or she may have to use old batteries of reduced capacity.

Should the battery ownership rest with the chain of charging depots then the owner would have to pay for current and battery rent and would have the privilege of purchasing the vehicle without a battery. Such a free exchange of batteries would call for requisite standardizing of battery trays, and control features, motors, etc.

Climbing the Ladder

LIMOUSINE body types, longer wheelbases, more accessible batteries, more fool-proof control, approaching battery standards, attempted regulation of vehicle speeds or recommended practice in such, dropped frames, improved springs, shaft drive or inclosed methods, etc., are a few of the new rungs added to the ladder of electric vehicle progress.

All indicate that the electric vehicle maker is aiming to impress on the buyer the paramount fact that the electric passenger vehicle is a general utility vehicle the same as the gasoline machine.

With the electric commercial vehicle there is a pronounced movement to enlarge the number of models to take in the varied requirements of every industry.

Salon Breaks World's Record for Exhibitors

PARIS, Dec. 22—With the record number of 550,000 persons having paid for admission, the thirteenth French automobile show closed its doors this evening after having been open 16 consecutive days. No accurate record has been kept of the number of persons having entered the big hall with free tickets, these persons comprising stand attendants, agents, officials, pressmen, and persons having received invitations on the opening day. It is estimated that altogether nearly one million persons must have entered the Grand Palais while the show has been in progress.

It is evident that the show which has just been brought to a close is the most successful ever held in France. Gate receipts are about $6,000 in excess of the best previous year; the amount paid for the rental of stands is $40,000 in excess of the previous record, and the 568 exhibitors is the highest number recorded in any show in any part of the world. These 568 exhibitors occupied 260,000 feet of floorspace, paid at rates varying from $50 to $60 per square yard.

In an interview with THE AUTOMOBILE representative, Henri Cezanne, general secretary of the show committee, stated that the organization of the show had cost from $250,000 to $300,000, this being the largest amount ever spent on any automobile show. The electric light bill worked out at the rate of $500 an hour.

"It has been decided," declared M. Cezanne, "to hold an automobile show in Paris next year, most probably during the month of October instead of the month of November. This change of date will be adopted in order to diminish as far as possible the present annual slack season. It is found that there is a falling off in the amount of business done from the month of July, and the increase in business is not felt until after the show. If the show is not held until the month of December the slack season is felt more or less for 4 months. If the show is held in October, this period of slackness will only last for 2 months."

Up to the present the London show has opened the European series, and the British trade has always laid emphasis on the fact that London was the centre of the European automobile trade. The unprecedented success of this year's Paris show has begun to shake the Englishman's belief in the impregnability of Olympia, and with such natural facilities as the French enjoy in the Grand Palais and the determined effort they are now making to retrieve their former mistakes, it hardly seems possible that London can remain more important than Paris as a trading centre.

"Personally I do not consider that an annual show is worth while," explained M. Cezanne, "and there are plenty of manufacturers who are of my opinion. Experience has shown us that the annual show does not increase the volume of business. It undoubtedly helps the small firms to come to the front, and it enables foreigners to get on our market. It is really more advantageous for us to take part in shows in foreign countries than to exhibit at home. The settled condition of automobile design is another reason why shows should not be held every year. Although 2 years have elapsed since a show was held in Paris, the mechanical changes are not of sufficient importance to necessitate such a costly demonstration as the Paris Salon.

"Until we can come to an agreement with the English manufacturers, by which the two shows will be held every 2 years—not alternatively—we shall be obliged to hold a show in Paris every year. A show in Paris one year and in London on the following year is not desirable, for practically the same preparations have to be made by our manufacturers to exhibit in London as to participate in the Paris show. This arrangement therefore amounts, practically, to an annual show. As soon as the English declare that they are ready to work with us in the organization of shows every 2 years we shall abandon the annual exhibition."

"Business has been excellent," declared M. Cezanne. "It is obviously impossible to state what amount of business has been transacted with the Grand Palais, but in every section of the show—car manufacturers, body makers, tire makers and dealers, accessory dealers—the statement is made that business has been decidedly brisk."

Out of the profits of the show 40 per cent. is returned to the exhibitors in proportion to the amount paid by them for the rental of stands; 40 per cent. is returned to the exhibitors who for 6 months have been members of one of the organizing trade associations, and 20 per cent. is paid over to the 5 organizing associations in proportion to the amount paid by their members for stand rental.

The Paris salon is admittedly the most important social function of its kind. The decorations and illuminations are designed to attract the attention of the wealthy classes, yet the price of admission is kept sufficiently low to suit practically everybody, being only 20 cents on all days but Fridays and the opening day, when it is increased to 60 cents and $1, respectively. The Republican Guards military band is secured for the opening day, this band being recognized as the finest of its kind in Europe. On all other days a very high class orchestra is secured, and on Fridays there is in addition a short concert with singers from the National Opera House. It cannot be denied that these attractions bring into the hall the right class of prospective automobile buyers.

The show has always closed its doors at 6 o'clock. This year, by special request, they were kept open until 6.30 o'clock, but on a careful account being taken it was found that the number of people entering during this last half hour was only 31. As the additional half hour entailed an additional expenditure of $300 for light and attendance, the experiment was naturally looked upon as a failure.

One of the most valuable conveniences in the hall was a system of electric lights to indicate the position of stands. On large boards near the main entrance a plan of the entire show had been prepared, and in the center of each stand marked on the plan a small electric lamp had been fitted. By the side of the board was a complete list of firms exhibiting, with an electric light button immediately after the name. By pressing this button a red light was made to appear on the stand shown on the plan. As a rapid means of finding the location of any stand it was most valuable and was highly appreciated by the visitors.

Philadelphia Show Has Sixty Exhibitors

PHILADELPHIA, PA., Dec. 28.—Drawings for the allotment of exhibition space to local pleasure car and accessories dealers, to hold forth during the first week of the twelfth annual Philadelphia Automobile Show at the Automobile Club of Philadelphia's building, Twenty-third and Market streets, January 18 to February 1, were held on Thursday and show a total of over sixty different makes of gasoline and electric cars, handled by dealers affiliated with the Philadelphia Automobile Trade Association, under whose auspices the exhibition will be conducted. This number will be considerably augmented next week when dealers not members of the association will draw for space. The opposition show to be conducted by the Philadelphia Automobile Board of Trade, Ltd., at the First Regiment Armory, Broad and Callowhill streets, during the week of January 18 to 25, will make a feature of foreign-built cars in addition to representative American cars.

After Big Races for 1913

Both Milwaukee and Savannah Want the Grand Prix and Vanderbilt Cup Contests This Year

Committees To Visit New York Regarding the Matter in the Early Part of This Month

BOTH Milwaukee and Savannah want the big cup races for 1913. They have not been awarded so far but the following items show the interest and hope of the cities actively campaigning for them.

MILWAUKEE, WIS., Jan. 1—It is announced today on the very best of authority that Milwaukee will stand sponsor for the international road races, the grand prix, Vanderbilt cup, Pabst trophy and Wisconsin Challenge cup races in 1913, if the governing bodies, the Automobile Club of America and the American Automobile Association will again consider its tenders favorably. Immediately after the fifth annual Milwaukee motor show, which is to be given in the Auditorium from January 11 to 17 inclusive, the Milwaukee Automobile Dealers' Association, will begin preparations for its campaign to land the classics a second time, and a delegation will leave for New York to make its tender to the governing body.

SAVANNAH, GA., Dec. 30—The date and other details of the Grand Prix and Vanderbilt cup automobile races, which will in all probability be held in Savannah, over the famous Chatham County course, either in the fall of 1913 or early in 1914, will be arranged at a meeting to be held in New York on January 6 between the Motor Cups Holding Company and a sub-committee from the executive committee of the Savannah Automobile Club.

The committee will leave Savannah Saturday night, January 4, reaching New York the following day. The meeting will be held at the Waldorf-Astoria on Monday, January 6.

It is stated by President Granger that there is a possibility of the races being held on February 22, 1914, instead of Thanksgiving Day, 1913, as heretofore, the former date being favored by the Automobile Club of America.

Records Broken in Iowa Road Run

DAVENPORT, IA., Dec. 29—All records were shattered for daylight run across Iowa yesterday when Don McClure, Oskaloosa, driving two-passenger Oakland torpedo, won the 321-mile race by 35 minutes over Pete Petersen, Davenport, driving five-passenger Pope-Hartford. McClure's total time on the road was 10 hours and 43 minutes while Petersen took 11 hours and 18 minutes. McClure's running time was 9:20 and Petersen's 9:24.

The race was arranged by the Tri-City Ocean-to-Ocean Official Highway Association to determine whether the River-to-River road or Great White Way was the better route between Davenport and Council Bluffs. Petersen drove over former and Oskaloosa man took the southern route. The River-to-River road is 346 miles and the Great White Way 321 long but drivers raced on equal terms. Average time of winner 37.8 miles per hour.

More Space Available for Chicago Show

Many belated applicants for space at the Chicago Automobile Show, who have been greatly disappointed by the fact that no more exhibition space was to be had in the Coliseum, Annex or First Regiment Armory during either the first or second week of the show, will, after all, be given exhibition space. By one of his customary enterprising business deals, Manager S. A. Miles has secured the use of the Wilson building, adjoining the Coliseum Annex on the South, for the show period. This building is practically the same size as the Annex and the floors are free from obstructions of any sort. This will enable the largest passenger cars and motor trucks to be shown to advantage without any interference by posts or low ceilings. The building has a main entrance on Wabash Avenue, but by opening passage ways through the south wall of the Annex, it can be made to all intents one building with the Coliseum, so that space in it will be even more desirable than in the Annex.

With these additions the count of exhibitors in the show will be as follows:

Passenger car manufacturers, 102; commercial vehicle builders, 77; accessories manufacturers, 244. Most of the accessory exhibits will remain in place throughout both weeks.

Spaces in the Wilson building have been taken by the Mercer Automobile Co., and Midland Motor Car Co., previously allotted Annex basement spaces; Paige-Detroit Motor Car Co., allotted space in the Armory; and the W. H. McIntyre Co. The Republic Motor Car Co., of Hamilton, O., and Century Electric Car Co., of Detroit, Mich., have accepted the basement spaces thus made vacant.

The new motor truck exhibitors who have accepted offers of space are the Grand Rapids Motor Truck Company, of Grand Rapids, Mich., Driggs-Seabury Ordnance Corp., Sharon, Pa., Randolph Motor Car Co., Chicago, Edwards Motor Car Co., New York, and the O. Armleder Co., Cincinnati.

Notice to New York Show Exhibitors

Merle L. Downs, secretary for the coming automobile shows at New York, has issued the following statement:

In order that there may be no misunderstanding in regard to shipment of exhibits, or delay in receiving same at this end, we call your attention at this time to paragraph 11, of the rules, copy of which has been sent you, and which is included in your contract for space, with reference to shipments, and especially to that portion of the same, which states all freight and express charges must be prepaid, or the goods will not be accepted by the management.

This is important, so kindly see that the necessary instructions are given your shipping department at this time.

We also desire to remind you that in view of the prevailing freight situation, and the fact that it is not always possible to get freight cars on short notice, that after a consultation with the traffic department, would suggest that you place orders promptly with the railroad for cars to take care of your usual shipments in ample time, so that there will be no delay in getting your exhibits here in time for the opening. We bring this matter to your attention, owing to the numerous inquiries that have been made from exhibitors on the subject.

Lanchester Brings Out Vibration Absorber

BIRMINGHAM, ENG., Dec. 21—F. W. Lanchester, consulting engineer of the Daimler Company, has recently brought out a vibration absorber for four-cylinder motors. It consists of a twin cross-shaft driven from the motor crankshaft and carrying balance weights, which revolve at double crankshaft speed. Mr. Lanchester in speaking of the necessity for such a device on a four-cylinder motor recently stated: "The orthodox form of four-cylinder engine is correctly balanced so far as the primary reciprocating forces are concerned, but the secondary balance is appreciably bad, and at high speeds causes much vibration. This lack of secondary balance is due to the effect of the comparatively short connecting rods which cause the motion of the piston to differ from the ideal harmonic. In a four-cylinder engine with 4-inch stroke and pistons weighing two pounds each this secondary unbalanced force at a speed of 2000 revolutions per minute exceeds 400 pounds."

Tire Plant for Louisville

Speedway Tire Company Organized by Louisville Men To Make Three Standard Types of Vehicle Tire

Willys Elected President of Gramm Truck Company—Car Census of the United Kingdom

WITHIN the next 90 days Louisville expects to boast of the only tire factory south of the Ohio River. The concern is the Speedway Tire Company, which has on hand $250,000.

All money is in and more than 65 per cent. of the capital stock is held in Louisville. The officers of the new company are Harry L. Lewman, of the Lewman-Cox Realty Company, president; L. D. Lewman, of Atlanta, president of the Manhattan Construction Company of New York, vice-president; Fred Haupt, of Louisville, second vice-president; W. N. Cox, president of the Louisville Public Warehouse Company, treasurer; and Dr. Fred L. Koontz, secretary. G. W. Greene, a tire expert of Massachusetts, will have charge of the new plant.

Two sites for the factory are now under consideration. The plant, according to present plans, will be placed in a factory building, which will be altered to suit present needs. A lease with a buying option will be taken. As soon as it is known what are the needs of the new company, the concern expects to build a modern tire factory eight stories high of concrete, steel and glass construction.

At first only motor vehicle tires of three standard types will be manufactured. The output will be about 100 tires per day. Pneumatic and solid automobile tires will be the principal product, but the firm will also make rubber mechanical goods and druggist supplies. About 300 men will be employed in the plant.

Willys Elected President of Gramm

TOLEDO, Dec., 27.—John N. Willys, president of the Willys-Overland Company, Toledo, was elected president of the Gramm Motor Truck Company, at the annual meeting of the stockholders of the corporation in Lima, O., Thursday evening, December 26. Mr. Willys has announced that the facilities of the plant will be doubled early in the new year and that the company will install special equipment for the building of a .75-ton truck to be placed on the market at a moderate price. The plant is now turning out 5-ton trucks. It is also announced that H. H. Doehring, for several years general sales manager of the Ohio Electric Car Company, has been made sales manager of the Gramm Motor Truck Company, with headquarters at Lima.

N. A. A. M. Establishes Office in Detroit

DETROIT, MICH., Dec. 30—The National Association of Automobile Manufacturers has established a traffic office in Detroit, in charge of J. A. Gardner, formerly traveling manager for the Brush and later with the Stoddard-Dayton, of Dayton, Ohio. Some of the work of the New York office will be transferred here and the local office will take up the matter of securing better transportation facilities for Detroit automobile manufacturers.

Car Census of United Kingdom

LONDON, ENG., Dec. 21—Among other interesting information contained in Lord Montagu's weekly journal, *The Car*, the car census reveals in a convincing manner the growth of the motor-car in these islands. To begin with there are 320,119 motor vehicles of all types in the United Kingdom, compared with 266,258 of last year, representing an increase of 53,861, while the total number of persons holding driving licenses is 284,799, of which 19,635 hail from Scotland and 10,626 from Ireland. With regard to the distribution of the cars throughout the United Kingdom, England and Wales, including the county boroughs, possess 156,573 motor carriages and pleasure cars, 116,248 motor-cycles, and 11,771 heavy commercial motor vehicles. The actual figures for the city of London are not only interesting but also instructive and convey to the lay mind the increase that is taking place annually. There are 55,912 motorcars, 20,654 motorcycles, while there are no fewer than 4,868 industrial motor vehicles registered in the metropolis. The London County Council have issued 49,482 licenses to drivers during the past twelve months, while the metropolitan police issued up to October 31 licenses for 7,896 motor-cabs, and 2,677 motor-omnibuses, as compared with 7,476 cabs and 1,883 motor omnibuses at that date 12 months previously.

Flanders Mfg. Co. Creditors to Present Claims

DETROIT, MICH., Dec. 30—*Special Telegram*—The Detroit Trust Company, receiver for the Flanders Manufacturing Company of Pontiac, has notified creditors to present their claims within 90 days, at which time an attempt will be made to have the property appraised. The factory is running at present. At the end of 90 days the creditors will hold a meeting, with the receiver, for the purpose of determining the future of the concern.

Winton Chauffeurs Get Cash Awards

The annual award by the Winton Motor Carriage Company to chauffeurs of Winton cars whose mileage was high during the past year with a minimum of repair expense has been made. The first prize of $1,000 went to a Boston chauffeur who submitted sworn affidavits by himself and his employer that he had driven the car 26,987 miles with no repair expense.

Nineteen other awards were made ranging from $500 to $100.

The plan followed by the company in determining who should receive the awards is to have the chauffeurs and owners report monthly to the company and the reports and affidavits are submitted to a committee of five which makes the awards.

Award	Driver	Place	Mileage	Repair Expense
$1,000	J. L. Dondero	Cleveland, O.	26,987	...
500	W. J. Green	Chicago, Ill.	22,928.8	...
250	Thomas Murren	Medford, Mass.	16,477	$0.95
150	Albert Bedard	Providence, R. I.	18,245.3	18.01
100	E. P. Bruhaker	Chicago, Ill.	15,729	...
100	J. W. Tracy	Crafton, Pa.	14,022	...

Date Set for Du Brie Hearing

DETROIT, MICH., Dec. 30—The DuBrie Motor Company, adjudged bankrupt October 4, has filed a petition in the United States court, asking a full discharge of all debts provable against it under the bankruptcy acts. Judge Arthur S. Tuttle has set February 3 as the date for a hearing and has notified creditors to appear at that time and show cause, if any, why the prayer of the petitioner should not be granted. The company declares it has surrendered all its property and rights of property and has fully complied with the requirements of the bankruptcy acts.

Pelletier and Smith Leave Flanders Co.

Advertising and Sales Managers Suddenly Sever Their Connection with New Subsidiary of U. S. Motors

Flanders Company Files $600,000 Mortgage to Secure Bond Issue—Speedwell Issue Subscribed

DETROIT, MICH., Dec. 30—*Special Telegram*—E. Leroy Pelletier, advertising manager, Flanders Motor Car Company, and Paul Smith, sales manager, severed their connections with that concern on December 28. No statement from the parties concerned nor from the officers of the Flanders Company could be obtained today relative to the reasons for the move. Since the merger of the Flanders Motor Car Company with United States Motors, there has been considerable speculation as to whether these men would assume the same positions with the parent organization, and Saturday's move is the answer.

A newspaper report here today states that Pelletier and Smith were advertising and sales manager, respectively, of the United States Motors Company at the time of their resignations, but this is incorrect. They were connected with the Flanders subsidiary only and were not in the employ of the United States Motors in any capacity.

Semi-official confirmation of the fact that Smith and Pelletier have quit the Flanders Motor Company has been received in New York. It is also stated that while they were slated for the positions of sales manager and advertising manager of the contemplated reorganization of the United States Motor Company, their appointments had not been made officially.

The report from Detroit states that the split occurred last Saturday but the reasons underlying it were not outlined.

The whole industry as represented in New York displayed the keenest interest in the report but could add nothing to it.

Flanders Files $600,000 Mortgage

DETROIT, MICH., Dec. 30—The Flanders Motor Company has filed with the city clerk copies of a $600,000 chattel mortgage, running to the Central Trust Company to secure an issue of 6 per cent. 3-year gold bonds, arrangements for which were made with the New York concern some time ago.

Speedwell Bond Issue Subscribed

DAYTON, O., Dec. 27—Stockholders of the Speedwell Motor Car Company, Dayton, O., met in that city last Tuesday and ratified the plan recently projected to authorize a bond issue of $150,000 for the extension of the business. This issue has not been subscribed, according to the company. It was also decided to increase the directorate of the corporation. President Pierce Schenck stated that Fred A. Funkhouser, president of the Winters National Bank of Dayton, will be one of the new directors. W. L. Caten was elected vice-president and general manager of the company at the Tuesday afternoon meeting. The Mead sleeve engine will be used in the cars of the concern in the future, and leading stockholders of the Mead Engine Company will take stock in the Speedwell Company and the plant will be enlarged.

Grabowsky Sold—Lion Sale Postponed

DETROIT, MICH., Dec. 31—*Special Telegram*—The referee in bankruptcy today accepted the offer of Samuel Winternitz and Company, of Chicago, for a part of the property of the Grabowsky Power Wagon Company. Winternitz and Company will sell the material and machinery and turn $55,000 over to the referee. The bid covers everything but the land, buildings, equipment, book accounts and bills receivable. The real estate will be sold by the referee at auction January 23 at the plant.

The sale of the Lion Motor Company property at Adrian, Mich., has been postponed by the referee for the second time. On the date first set for the sale the highest bid was $7,000 for property appraised at about $33,000. On December 24 another attempt was made to sell the property but on that occasion the highest bid was $12,250, this being from Samuel L. Winternitz of Chicago. This sale likely will be confirmed unless a bid of $12,750 is received before the date set for the sale.

A delegation of Adrian business men were in Detroit when the sale was postponed for the second time and members stated they believed they could procure a buyer who would pay $12,750.

Gear Company Changes Its Name

ALBANY, N. Y., Dec. 28—The New Process Gear Corporation has been incorporated in Albany with a capital stock of $1,000,000, all subscribed. The new company will, on January 1, take over the stock of the New Process Raw Hide Company.

Originally the manufacture of rawhide gears was the principal business of the company. Now it makes both metal and rawhide gears, the production of metal gears being many times greater than that of rawhide.

The New Process Company is now doubling its plant and capacity. A large extension to the factory in Plum street is nearing completion and will be wholly occupied when it is completed.

Freight Car Shortage Slightly Less

While demand for freight cars is still unprecedentedly severe, another reduction in the net shortage was reported by the American Railway Association for the fortnight ending December 14

Automobile Securities Quotations

AUTOMOBILE and accessory securities had a quiet week on the bourses. The general tone was firm but in the limited trading, due to the holidays, the market trend was somewhat irregular. Tire stocks were the strongest feature of the market with Goodyear and Firestone close to the record mark. Compared with the level of the last day of 1911, stocks show a material advance.

and unofficial information since that date indicates that still further reductions in the shortage have been made. At the time of the report there was a net shortage of 34,392.

Last year at this time there was a net surplus of freight cars of 76,814; thus the showing for this year is 111,000 less than last year at the corresponding time.

Heavy snows in several sections delayed freight operation to some extent, but not sufficiently to produce congestion. At latest reports the cars are moving rapidly, but in volume never before equalled in this country. The next fortnightly report, covering the situation up to December 28, will be issued early in January, and it is expected to show a reduction of the net shortage to below 20,000 cars.

Six Elected by M. & A. M.

At a meeting of the Motor and Accessory Manufacturers on December 26, the following concerns were elected to membership:

The Dayton Malleable Iron Company, Dayton, O.; Herschell, Spillman Company, North Tonawanda, N. Y.; North East Electric Company, Rochester, N. Y.; Penberthy Injector Company, Detroit, Mich.; The Portage Rubber Company, Barborton, O.; Tyer Rubber Company, Andover, Mass.

U. S. Motor Issues No Certificates

According to official announcement of the United States Motor Company, the receivers have decided not to take advantage of the authorization of court to actually issue the $1,500,000 of receivers' certificates, permission to do which was given by United States District Judge Hough under date of October 28. The receivers state that pending the judicial sale of the properties, scheduled for January 8, manufacturing schedules will be followed only as hitherto outlined; consisting largely of operations to maintain existing cars.

Market Changes for the Past Week

QUOTATIONS for materials during the past week varied but little from those of the preceding week. The holidays were responsible for a rather noticeable limitation of activity and prices remained at their old levels in almost every case. Steel, copper and lead suffered no change, but tin advanced slowly and steadily throughout the week. It closed 0.5 cent higher per pound than it had opened after Christmas.

Lubricants, oils and fuels remained likewise at their old prices. Cottonseed oil fluctuated a little, but the principal products, petroleum and gasoline, closed as they had opened and without any tendency toward a change of prices.

Japanese silk declined slightly, whereas the Italian product remained at its old price. Outside of the changes just enumerated none took place. The table of prices follows:

Material	Wed.	Thurs.	Fri.	Sat.	Mon.
Antimony, per lb.	.09	.09	.09	.09	.09
Beams & Channels, 100 lbs.	1.61	1.61	1.61	1.61	1.61

Stoddard-Dayton to Fight for License

Receivers Decline Notice of Cancellation Served Upon the Company by the Owners of the Knight Patents

Testimony Taken in Huber Patent Case—Hardie Buys Interest in Miller Car Company

ANNOUNCEMENT was made last Thursday by receivers of United States Motor Company that notice of cancellation served upon the Dayton Motor Car Company with reference to the license of that company under the Knight sliding-sleeve engine patents had been declined on the part of that company.

Counsel representing the Dayton Motor Car Company have advised the company that in their opinion the contract between the Knight company and the Dayton Motor Car Company contains nothing upon which such cancellation order can be based, predicated upon any act so far performed by the Dayton Motor Car Company.

According to the receivers no move has yet been made to deliver a similar notice of cancellation to the Columbia Motor Car Company.

It was stated with color of authority that the chances favored an immediate withdrawal of the demand for cancellation of the Stoddard-Dayton license.

This is said to be due to the promising prospects of the United States Motor Company, the judicial sale of which is scheduled to take place January 8.

Up to date the creditors' committee reports that slightly in excess of 97 per cent. of all claims against the company have been filed and that before the date of sale practically the whole mass of claims will be represented by the committee.

The second call on the assessment directed to the stockholders was promptly paid by a sufficient number to constitute a majority of the outstanding issues, according to statements of the reorganization committee.

Testimony Taken in Huber Case

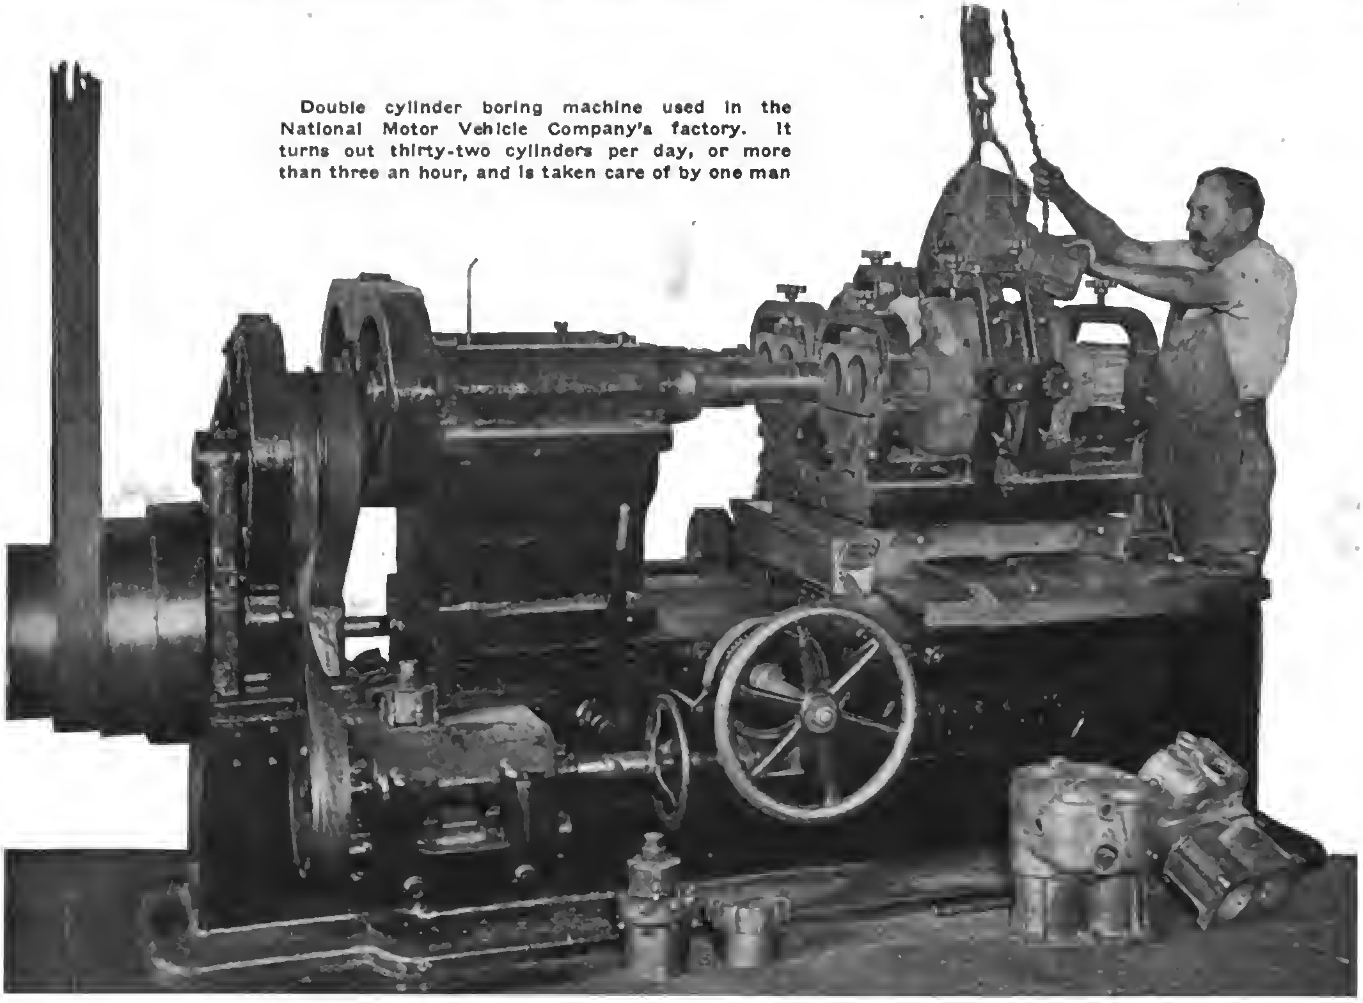
DETROIT, MICH., Dec. 30—In an effort to establish a *prima facie* case in the alleged patent infringement case of the North American Vehicle Company against the Detroit Taxicab & Transfer Company, in the federal court at Detroit, Attorney R. A. Parker, representing the complainants, took the deposition of Charles E. Wisner, mechanical designer and engineer, before E. P. Voorheis, United States Court Commissioner. The case involves the Emil Huber patent on three-point suspension of the motive mechanism to the main frame of an automobile and is being defended by the Kelly Motor Truck Company of Springfield, O., whose trucks the Detroit company is using. Engineer Wisner's testimony was to the effect that he considers the variation between the mechanism of certain portions of the truck and the Huber patent immaterial.

Hardie Takes Interest in Miller

DETROIT, MICH., Dec. 30—*Special Telegram*—James M. Hardie, who has been Chicago sales representative of the Miller Car Company of Detroit, has purchased stock in the company and has become secretary, treasurer and general manager. J. C. Hallock, whom he succeeds as secretary and treasurer, will confine more of his energies to the Detroit Excelsior Company, with which he is identified. According to Mr. Hardie the business of the Miller Company will be increased.

Factory Miscellany

Double cylinder boring machine used in the National Motor Vehicle Company's factory. It turns out thirty-two cylinders per day, or more than three an hour, and is taken care of by one man



CUTTING the time of a job in two without the use of extra men means the saving of money. The machine for boring cylinders shown in the above illustration does that very thing. It bores two cylinders at a time and requires the attention of one man. National cylinders are cast in pairs and are of the T-head type. The two cylinders in one block are too close together to work upon at the same time, therefore two blocks are placed in the machine and the outside cylinder in each block is bored. After this operation they are reversed by the aid of a chain fall and a device that looks like an ice tongs and the other two cylinders are bored. The T-head shape of the casting renders this possible on account of the symmetry. Sixteen pairs, or thirty-two cylinders are bored in one day of 10 hours, averaging 3.2 cylinders to the hour or about one cylinder every 19 minutes.

MOON Increased 65 Per Cent.—The Moon Motor Car Company, St. Louis, Mo., has increased its capacity about 65 per cent. in the last few months. This has been achieved by the addition of extra floor space in the building of an extra story and a building attached to the main building, all of which new space has been filled with machinery and is now in operation. The rear axle department recently added a number of new boring mills, and presses, one of 25-ton capacity. The testing department has been moved into a separate building, occupying much more floor space than formerly and now operated under its own power. The company is taking in new men daily and training them into the work.

Another Tractor Factory—The Canada Standard Automobile & Tractor Engine Company, Moose Jaw, Sask., is having plans prepared for a new factory.

Ravenna's Plant—The Ravenna Auto Truck Company, Ravenna, O., is erecting a plant 50 feet by 150 feet, for the manufacture of the Ravenna automobile truck.

Fedders Building—The Fedders Manufacturing Company, Buffalo, N. Y., automobile radiator maker, is building an addition to its plant at Tonawanda street and West avenue.

Chapin Autocycle Builds—The Chapin Autocycle Company, Brantford. Ont., recently incorporated with a capital of $200,000, will erect a factory, employing about 100 men.

Armitage Leather Company Builds—The Armitage Leather Company, Detroit, Mich., recently incorporated with a capital of $35,000, has established a plant at 87 West Congress street.

Louisville Concern Builds—Miller, White & Company, Louisville, Ky., recently incorporated with a capital of $5,000, has secured quarters at Third and Walnut streets, and is now buying machine tools.

Tractor Company Adding—The Killen-Walsh Manufacturing Company, Appleton, Wis., has leased the Double Power Wind Mill Company's plant at that city and is already engaged in the construction of additions.

New Bridgeport Factory—The Bridgeport Auto Company, Bridgeport, Conn., is starting work on its new factory, which is expected to be one of the largest automobile, motor boat and aeroplane factories in the world.

Miller Rubber Factory—Work will be started at once on erecting a four-story brick, steel and concrete factory building for the Miller Rubber Company, Akron, O., to cost $80,000.

Petrolea Planning Addition—The Petrolea Motor Car Company, Petrolea, Ont., plans an addition to its automobile factory in that city. A by-law will be submitted to the taxpayers to grant a $10,000 bonus for the extension.

Budd Building—The Budd Manufacturing Company, Philadelphia, Pa., is having plans prepared for a three-story factory building, 75 feet by 500 feet, to cost about $100,000. The company is manufacturing steel automobile bodies.

Anderson Gear Company Operating—The Anderson Rolled Gear Company, Cleveland, O., has taken over the new plant of the Cleveland Drop Forge Company, and is now operating a number of gear rolling machines on both spur and bevel gear work.

Prest-O-Lite Plant Explodes—The plant of the Prest-O-Lite Company, Indianapolis, Ind., exploded recently. The watchman was killed. The loss was $30,000. The explosion is believed to have come from the boiler, with the result that the plant ignited.

Plant Being Enlarged—The Craig-Center Auto Company, Pittsburgh, Pa., has secured additional vacant property on which it intends to erect additional buildings for show rooms and factory purposes. The new building will have a total floor space of 18,000 square feet.

Herring in New Quarters.—The Herring Motor Company, Des Moines, Ia., is moving into a four-story brick building. One entire floor of the building will be given over to the assembling plant where twenty Ford cars are assembled daily. Another floor will be used by the Herring Motor Supply Company.

Lee & Porter Building—The Lee & Porter Manufacturing Company, Buckhannan, Mich., makers of automobile axles, will at once proceed with the work of erecting a frame addition, with concrete foundations, to its plant, which will be 32 feet by 90 feet. About $8,000 worth of new machinery will be installed.

Club for Goodyear Employees—The Goodyear Tire & Rubber Company of Canada, Bowmanville, Ont., is taking care of its employees in a manner that tends to promote the best feeling between the company and the employee. It has purchased the Balmoral Hotel at Bowmanville and turned it into an up-to-date club for the benefit of the members of its staff.

Plans Another Addition—With two new buildings, aggregating 75,000 square feet of floor space, nearing completion, the Chalmers Motor Company, Detroit, Mich., now announces the erection of a third structure. This new building will be used for general manufacturing purposes and will have 24,000 square feet of floor space. It will be one story in height and 160 feet by 150 feet.

Alco Plant Splendidly Equipped—Among the noteworthy features of the American Locomotive Company's, Providence, R. I., plant is a heat-treating department, having twenty-one furnaces, all run by an automatic instrument, which prevents the metals from being burned. Then there is a chemical laboratory, also a physical laboratory to determine strains and shocks. Another feature of the plant's equipment is a 250,000-pound steam hammer, which cost $51,000 and is the largest in the country. It is used to drop forge the Alco axles and crankshafts. The plant includes twelve buildings on a ten-acre plot.

Factory of the Moon Motor Car Company, St. Louis, Mo.

One of the views along the Pacific Highway on the borderline between the States of Washington and Oregon

AMERICAN Cars in Majority—Practically all cars purchased in Bahia, Brazil, during 1912, were of American manufacture. Previously the sales had been confined to European cars. The change was due to the fact that two large hardware firms imported a number of American cars. That the Bahia public thought them superior to European cars was evidenced by the early sale of all cars on hand. Larger stocks of 1913 cars are being laid in.

Philadelphia Pullman Moves—The Pullman Automobile Company, Philadelphia, Pa., has moved to 1927 Market street.

Golde Top on Edwards—The Edwards car, manufactured by the Edwards Motor Car Company, New York City, is to be equipped with the Golde patent top.

Republic's St. Louis Branch—The Republic Rubber Company, Youngstown, O., will establish a branch at 2018 Locust street, St. Louis, Mo., with G. M. Hoffman as manager.

Chase Establishes Factory Branch—The Chase Motor Truck Company, Syracuse, N. Y., has established a factory branch in Philadelphia, Pa., with E. F. Howell as manager.

Building New Garage—The Garrison Garage Company, Baltimore, Md., has been formed and is building a handsome garage to accommodate the increased number of automobiles.

Baltimore Secures Show Building—Formal announcement is made that the Fifth Regiment Armory, Baltimore, Md., has been secured again for holding the automobile show from February 18 to February 22, inclusive.

Caten Vice-President—W. L. Caten has just assumed the office of vice-president and general manager of The Speedwell Motor Car Company, Dayton, O. This involves no change in any other officers of the company.

Stage Line in Wisconsin—The first stage line in Wisconsin since the days when horses were hitched to lumbering wagons, has been established between Kiel and Manitowoc, a 45-horsepower KisselKar forming the medium of transportation. The coach seats 32 persons and a driver, and has space for small luggage.

License Yellow and Black—The new automobile licenses for 1913, in Maryland, will be of yellow numbers on black background. These licenses are now being distributed at the office of Motor Vehicle Commissioner Roe.

Heinz Company Organized—The Heinz Motor Company, Baltimore, Md., has been organized and will be located at 533 North Howard street, where it will handle a full line of automobile tires and accessories, as well as automobiles.

Barger Rambler Representative—The Thomas B. Jeffery Company, Kenosha, Wis., makers of Rambler cars, has appointed W. H. Barger, Cleveland, O., as representative for the Cross Country model in that city and northeastern Ohio.

Barnes Promoted—W. R. Barnes has been promoted to district supervisor over the six factory branches of the Goodyear Company, located in Philadelphia, Pittsburgh, Scranton, Pa., Baltimore, Md., Washington, D. C., and Richmond, Va., with his headquarters in Philadelphia.

Colorado's Second Automobile Stage—The establishment of the second automobile stage in Pueblo County, Colorado, has just been reported. A high-powered automobile has taken the place of the old horse-drawn stage line between Pueblo and Beulah, a distance of 30 miles.

Biscuit Company Purchases Trucks—The Toledo Biscuit Company, Toledo, O., which has been experimenting with motor trucks for delivery purposes for some time, has decided to discard horses and has ordered a fleet of trucks from the Toledo Motor Truck Company.

Massachusetts State A. A. Banquet—The Massachusetts State A. A. has planned to have its annual banquet at the Hotel Somerset, Boston, Thursday evening, January 9, at which President Lewis R. Speare will preside and an address will be made by President Laurens Enos of the A. A. A.; George C. Diehl, chairman of the A. A. A. Good Roads Board; A. G. Batchelder, chairman of the A. A. A. executive committee; Colonel W. D. Sohier, chairman of the Massachusetts Highway Commission and President W. D. Parker of the Maine Automobile Association.

New Agencies Established During the Week

Move Salesrooms—Hess & Son will be located at 1031 Chestnut street, Philadelphia, Pa., after January 1.

Marble Purchases Company—W. H. Marble has purchased the personal property of the Leighton Auto Company, Brockton, Mass.

Gentry, Laplock Manager—H. C. Gentry has been appointed manager of the New York City branch of the Stein Laplock Tire Company.

Titus, Southern Alco Representative—F. J. Titus has been appointed southern representative of the American Locomotive Company, Providence, R. I.

Engler, Chief Engineer—W. B. Engler has been promoted to the post of chief engineer of the General Motors Truck Company, Pontiac, Mich. He will be in charge of the experimental and development work.

Cartercar's Atlanta Factory Branch—The Cartercar Company, Pontiac, Mich., has established an Atlanta, Ga., factory branch with W. C. Mahoney manager. The address of the new branch is 242 Peachtree street.

By Way of Correction—In the issue of THE AUTOMOBILE on December 19, 1912, a typographical error was made in describing the Marathon car. The Runner roadsters have three speeds forward, instead of two.

Moline Purchases Truck—Moline, Ill., is to purchase an additional fire truck, the city commission having decided to dispose of its remaining horse-drawn apparatus and increase the efficiency of the department with motor apparatus.

Pence Receives 150 Buicks—The Pence Automobile Company, Minneapolis, Minn., has received a train load of fifty freight cars of Buicks from the factory at Flint, Mich. The train left Flint December 24 and reached Minneapolis over the Milwaukee road December 27. The shipment was 150 automobiles.

United States Purchases Alcos—The United States Government has purchased from the American Locomotive Company, Providence, R. I., four trucks, two of which will be employed in army activities at the West Point post, and the others in salvage work in the fire department at Manila.

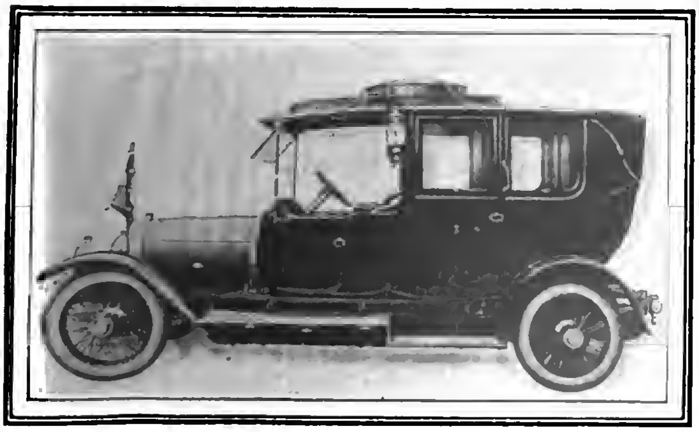
Want Ohio Assembly Aid—Extensive aid will be asked of the Ohio General Assembly this winter in the campaign of road building. The movement to have the General Assembly make direct levies for good roads has gained impetus since the defeat of the constitutional amendment to issue bonds.

Baltimore's Automobile Bank—The first automobile bank to be established in Baltimore, Md., went into service recently. This bank is used by the German-American Bank of Baltimore, and was put into service to enable the bank to accommodate its depositors in outlying sections of the city.

Milwaukee Company Bankrupt—The Bates-Odenbrett Automobile Company, Milwaukee, Wis., has been closed by involuntary bankruptcy proceedings. It is believed that a reorganization will be effected and the business, which apparently was one of the best in Milwaukee, continued.

Both Shaffers Add Agencies—R. M. Shaffer, of the Shaffer Manufacturing Company, Baltimore, Md., has become sales agent for the Pullman car, while Charles A. Shaffer, son of R. M. Shaffer, of the same company, has taken on the agency for the Selden car and will have offices and salesrooms with the company, which also handles the R. C. H. car here.

Want Ohio Assembly Aid—Extensive aid will be asked of the Ohio General Assembly this winter in the campaign of road building. The movement to have the General Assembly make direct levies for good roads has gained impetus since the defeat of the constitutional amendment to issue bonds. It is estimated that this would raise between $3,000,000 and $3,500,000 annually.



The Queen of the Netherlands' 30-horsepower Spyker automobile has been fitted with Rudge-Whitworth detachable wire wheels. The car, a torpedo-landaulet-limousine, carries a spare wheel on the right running board of the car and one on the roof of the body

The city of Baltimore now possesses an automobile bank, the Chalmers chassis and Zeil body here shown having been designed for the German-American Bank. The wooden body on the 30-horsepower chassis is finished as in steel and fully equipped for its purpose

Electric signs blazed at the Paris Salon and electroliers increased their magnificent impression

Marble Resigns—C. L. Marble, purchasing agent for the Abbott Motor Company, Detroit, Mich., has resigned.

Schott to Move—About January 1, S. W. Schott, Columbus, O., distributor for the Empire and Brush cars, will move his headquarters to 237 North Fourth street.

Frisco's Apparatus Complete.—San Francisco, Cal., has recently added a new high pressure Pope-Hartford hose wagon, which makes its fire fighting apparatus complete.

Coral for Surfacing Road—Coral is to be used in surfacing the new road which is to be built from New Orleans, La., to the Southern Yacht Club's properties on Lake Pontchartrain.

Washington Man Bankrupt—A voluntary petition in bankruptcy has been filed by Frederick K. Barbour, Washington, D. C., whose assets are listed at $4,438 and his liabilities at $9,021.

Erecting New Garage—The Yager Motor Car Company, Louisville, Ky., agent for the Hupmobile and Peerless cars, is erecting a new garage at Third avenue and the L. and N. railroad crossing.

Handles Walpole Tires—The Bracken Stanton Company, Columbus, Ohio, is the name of a new concern which has opened a tire business at Fourth and Gay streets and will handle the Walpole tires.

Tennant Resigns—C. A. Tennant, connected with the Sundry Department of the Franklin Automobile Company, Syracuse, N. Y., for the past five years, has resigned to accept a position with the Middlesex Bridge Company of New Brunswick, N. J.

Truck Proves Value—An automobile delivery truck furnished by the Post Office Department to the Selma, La., office has proven its worth. During the Christmas rush the use of the truck enabled the delivery of all mails on the usual schedules.

Adds Extra Garage—The T. C. Bradford Automobile Company, Wilmington, Del., has taken possession of the Postles garage, adjoining its garage, and is occupying both, additional room having been required since the Bradford Company inaugurated a taxicab service.

Wolverine Club to Move—The directors of the Wolverine Automobile Club have decided to move their headquarters not later than January 15. It is reported that the club will select the Tuller Hotel, where a dining room on the first floor will be converted into a clubroom 50 feet by 50 feet.

Shuman Cales Manager—C. S. Shuman, who has had charge of the Burn-Boston Battery Company's business in New York City, has ben made sales manager of the Automobile Supply & Manufacturing Company of Brooklyn, N. Y. This company makes the Newtone electric horn, also bulb horns.

Wilmington Company Adds—The Wilmington Automobile Company, Wilmington, Del., has opened an extension in the rear, with a frontage of about 100 feet. The rear section was a public stable until bought by the automobile company, which had it rebuilt. The main building and extension are of brick and concrete construction.

Studebaker to Move—The Studebaker Company, of Minneapolis, Minn., has made a lease for a three-story building, to be erected on a site 75 feet by 154 feet at Fourteenth street and Hennepin avenue in the heart of automobile row. Work will begin at once and the building will be ready by spring. The structure will cost about $75,000.

Des Moines Space Sold—All the space for the fourth annual Des Moines automobile show, to be held at the Coliseum March 3 to 14, has been sold and firms are still seeking admission. This in spite of the fact that the show has been lengthened to a two-weeks affair with pleasure cars only shown the first week. Arrangements are now being made for an overflow show.

Closes Garage—Following is the new policy of the Olds Motor Works to withdraw its wholesale branches in several cities and to handle the wholesale business through its factory at Lansing, Mich., the three-story garage at 728-730 South Fourth avenue, Louisville, Ky., the finest garage in Kentucky, has been sold. The consideration, it is understood, was close to $75,000.

Milwaukee's Two Cars—Milwaukee, Wis., has just placed in service two new motor police patrol and ambulance cars, built according to Milwaukee's specifications by the Kissel Motor Car Company, of Hartford, Wis. The cars cost $3,500 each and supplant three horse-drawn patrols now used by the

Automobile Incorporations

AUTOMOBILES AND PARTS

APPLETON, WIS.—Killen-Walsh Manufacturing Company; capital, $100,000; to manufacture an automobile tractor. Incorporators: W. H. Killen, W. L. Walsh, W. J. Walsh, William Strait.

BALTIMOAE, MD.—Maryland Motor Car Insurance Company; capital, $300,000; to insure automobiles. Incorporators: J. C. Fenhager, W. Whitridge, W. G. Bowdoin, J. P. Bonsal.

BOSTON, MASS.—R. B. Nettleton Company; capital, $1,000; to deal in automobiles. Incorporators: R. S. Barlow, S. G. Barker.

BOSTON, MASS.—Norwalk Motor Car Company; capital, $75,000; to deal in automobiles. Incorporators: C. C. Smith, J. W. Briggs, M. A. Beaudet.

CHICAGO, ILL.—Marmon Automobile Company; capital, $20,000; general automobile business. Incorporators: M. E. Horn, C. E. Worbstein, E. J. Ehlers.

CLEVELAND, O.—Praco Manufacturing Company; capital, $15,000; to manufacture automobile lamps. Incorporators: H. G. Smith, J. C. Hipp, T. J. Smith, Tony Laness, Dan Pfahl.

DETAOIT, MICH.—Detroit Armature & Motor Works; capital, $10,000; to manufacture automobile parts. Incorporators: W. J. Harting, J. S. Keightley, M. E. Reynolds.

JUNEAU, WIS.—Juno Motor Truck Company; capital, $125,000; to manufacture automobiles. Incorporators: L. C. Pautsch. H. A. Henning.

NEW YOAK CITY—Eureka Auto Dispatch; capital, $1,000; automobile express. Incorporators: R. C. Cuyler, J. C. Stewart, F. T. Lind.

MORAISTOWN, N. J.—Morristown Auto Company; capital, $25,000; general automobile business. Incorporators: J. J. Lyons, L. Van Gasbeek, A. Newkark.

NEW ORLEANS, LA.—J. A. Landry Motor Car Company; capital, $25,000; to deal in automobiles. Incorporators: J. A. Landry, J. B. Avegno, R. J. Monroes.

NEW YOAK CITY—Haverty's Taxicabs Incorporation; capital, $1,000; to carry on a taxicab trade. Incorporators: Charles O'Brien, Charles O'Brien, Jr., Margaretta V. Curran.

NEW YOAK CITY—Vaughn Car Company; capital, $1,000,000; to manufacture automobiles. Incorporators: R. C. Thompson, Julius Kahn, Paul Kammerer.

QUINCY, ILL.—Broadway Auto Sales Company; capital, $2,500; to deal in automobiles. Incorporators: Alex. Thompson, J. G. Stuart, J. G. Clough.

SAN ANTONIO, TEX.—Motor Car Supply Company; capital, $5,000; to deal in automobiles and accessories. Incorporators: C. P. Guthrie, H. B. Lyne, James Harrison, Will Harrison.

SOUTH BEND, IND.—Cadillac Motor Sales Company; capital, $10,000; to deal in automobiles. Incorporators: N. A. Otis, G. H. Grieger, E. W. Steinhart.

South, West and Bay View police stations. One horse patrol is abolished entirely.

Operated by Gasoline Motors—The Badger Electric Railway & Power Company, Jefferson, Wis., which is to build an interurban railway from Lake Geneva, Wis., to Watertown, Wis., via Jefferson, announces that it will operate its cars by gasoline motors instead of by electricity. It will be the first interurban or street railway line in Wisconsin to employ gasoline motors for this purpose.

Grossman Establishes English Branch—Upon his recent visit to London, Mr. Emil Grossman established an English company known as the Emil Grossman Company, under the management of Messrs. Krauss & Auerbach, at 144 Queen Victoria street, London, E. C. This branch will be the distributing depot and center of activity in Europe to support the invasion of Europe by the Red Head spark plug.

Smith-Hoppe Chalmers Agents—By taking on the Chalmers line, the Smith-Hoppe Auto Company, 215 Wisconsin street, now carries the two original lines of the Kopmeier Motor Car Company, of Milwaukee, Wis., the Detroit electric and Chalmers. The Kopmeier company now represents the Fiat and Flanders gas and electric cars, while Smith-Hoppe represents the R. C. H., Hupp-Yeats, Chalmers and Detroit.

Columbus Buys Automobile—The Columbus, O., postoffice has arranged for an automobile service for deliveries in the new parcel post system which becomes effective January 1. Postmaster Krumm has arranged for one automobile to take up the service at the beginning, but the number will be increased as occasion demands. It is believed a half dozen cars will be necessary to take care of the business within 6 months.

Spitzley and Bush Resign—B. C. Spitzley, general manager, and W. T. Bush, general sales manager, have resigned their connections with the Abbott Motor Company, Detroit, Mich., according to a report which has been confirmed. No statement has been given out by either of the officials and no inkling as to their plans for the future has been given to the public. Mr. Spitzler has just returned from a western trip for the company.

Concerning Franklin Conferences—A conference of the Franklin automobile dealers in the New England territory was held recently at the Franklin factory, Syracuse, N. Y., with Robert H. LaPorte, New England district sales manager, presiding. The Franklin dealers in the Pacific Coast territory will hold a conference at the Franklin factory on January 9, with John F. McLain, district sales manager of the coast territory, presiding.

Interior view of the Paris Salon at night, showing splendid scheme of illuminating the hall

Winter Sheboygan President—A. F. Winter has been elected president of the Sheboygan, Wis., Automobile Club, which recently was rejuvenated and now has a total of nearly 200 members. J. H. Optenberg was elected vice-president and Arthur F. Raab is the new secretary and treasurer. T. M. Bowler continues as counsel and will take an important part in the Wisconsin State A. A.'s work before the coming session of the Legislature.

Propose New Indianapolis Ordinance—The Hoosier Motor Club, Indianapolis, Ind., has asked the advisory commission to Mayor Shank, of that city, to indorse a proposed ordinance forbidding automobiles to go around street cars on the left-hand side. The club will submit such an ordinance to the city council at an early date and will use its influence to have it passed. The habit of going around street cars on the left side is regarded by the club as a dangerous one.

Indianapolis Has Successful Season—One of the best indications of the successful automobile business in Indianapolis, Ind., during 1912, was the large increase in the number of automobile licenses issued by the city, as compared with 1911. The number of licenses issued was 3466, as compared with 2600 in 1911. Licenses issued in 1912 were classified as follows: runabouts and roadsters, 1300; touring cars, 1802; light trucks, 172, and trucks of more than one thousand pounds, 192.

Galveston-Winnipeg Road—The final step was taken in logging the Meridian Winnipeg, Can., to Gulf automobile road, when J. C. Micholson, secretary of the Meridian Road Association arrived in Galveston, Tex., from Winnipeg, having covered a distance of 2,000 miles by automobile. There is a very important feature to this highway which should be borne in mind. Winnipeg, a city of 200,000 population, is so situated that Galveston, in point of actual distance, is the nearest deepwater port, with the exception of the Great Lakes outlets, which are closed to traffic several months out of the year on account of ice.

Automobile Incorporations

TORONTO, ONT.—McKinnon Motor Vebicle; capital, $100,000; to manufacture automobiles. Incorporators: T. S. Blues, G. B. Mansfield, D. J. McKinnon.

WORCESTER, MASS.—Maykel Automobile Company; capital, $12,500; to deal in automobiles. Incorporators: M. K. Maykel, M. L. Katz, A. Massad.

GARAGES AND ACCESSORIES

BIRMINGHAM, ALA.—Blacklock Tire & Rubber Company; capital, $3,000; to manufacture automobile tires. Incorporators: Kate Blacklock, Mary H. Bostick, H. Blacklock.

BRIDGEPORT, CONN.—Jones Pneumatic Tire Spring Companv; capital, $100,000; to manufacture automobile tires. Incorporators: Lyman D. Jones, E. E. Brandreau, Clarence R. Hall.

CHICAGO, ILL.—Aldine Auto Livery; capital, $2,500; automobile livery business. Incorporators: C. A. Dickinson, A. B. Lapbam, W. R. Scates.

DETROIT, MICH.—Armitage Leather Company; capital, $35,000; to manufacture leatber for automobile use. Incorporators: Edwin Armitage, W. S. Gurd, R. B. Gillespie.

JAMESTOWN, N. Y.—Eagle Garage Company; capital, $25,000; to engage in a garage business. Incorporators: S. B. Rubbins, Olive M. Spencer, George Rappole.

LOUISVILLE, KY.—Miller, Wbite & Company; capital, $5,000; to deal in automobiles. Incorporators: R. W. Miller, A. W. White, William Atix.

NEW YORK CITY—Favary Tire Company; capital, $300,000; to deal in tires and accessories. Incorporators: E. Favary, M. W. Brashears, C. S. Boyd.

NEW YORK CITY—Wholesale Automobile Tire Company; capital, $1,000; to deal in automobile tires. Incorporators: W. P. Cole, David Morris, Abraham Levy.

NEW YORK CITY—Macandaryba Tire Filler Company; capital, $25,000; to manufacture automobile tires. Incorporators: Moses Haas, Nathaniel Levy, G. A. Weingetz.

TOLEDO, O.—Rubber Nix Manufacturing Company; capital, $10,000; to mannfacture an insoluble compound containing no rubber invented by E. A. McLean. Incorporator: E. A. McLean.

WILLIAMSON, N. Y.—Williamson Garage Company; capital, $20,000; to carry on a general garage business. Incorporators: R. S. Carr, C. I. Dezutter, A. F. Raymor.

CHANGES OF CAPITAL AND NAME

COLUMBUS, O.—Peerless Motor Car Company; increase of capital from $3,000,000 to $10,000,000.

DETROIT, MICH.—Detroit Carriage Company; change of name to Detroit Body Company.

DETROIT, MICH.—Von Bloerck Motor Company; increase of capital from $10,000 to $100,000.

ANTI-Skidding Device—Comprising transverse members spanning the tire tread and being attached to their base so as to be capable of swiveling movement.

This patent refers to an anti-skidding device comprising anti-skid elements which are pivoted to the wheel and are provided with wear members, W, hinged at H. These wear members are so arranged that they overlap each other on the tire tread, as shown in Fig. 1. The anti-skid members are provided with resilient means, R, which yieldingly resist to the movement of the wear members W. This allows for a slight movement of the wear members on the tread surface, which is essential in preventing excessive wear of the latter.

No. 1,048,376—to Rudolph Thiesen and Campbell Thomas King, Jr., Atlanta, Ga. Granted December 24, 1912; filed December 23, 1911.

Baffle-Plate Muffler—In which liquid is used to guide the exhaust gases in their path.

Fig. 2 illustrates the subject matter of this patent, a muffler which has inlet and outlet ducts, the former, I, being connected to the exhaust pipe of the motor, and the latter, O1, to a body of liquid, whereby the gases escaping in this manner are silenced through their work of overcoming the resistance offered by a column of the liquid. A part of the muffler casing is formed as an expansion chamber, C, in which suitably constructed baffle plates, B and B1 are so arranged that the gases must pass through this chamber in a zigzag way, being afforded an opportunity for silent expansion while doing so. Means are provided for introducing a sheet or film of water across the path of the gas coming in through the inlet ducts, so as to cool the exhaust and somewhat reduce its volume.

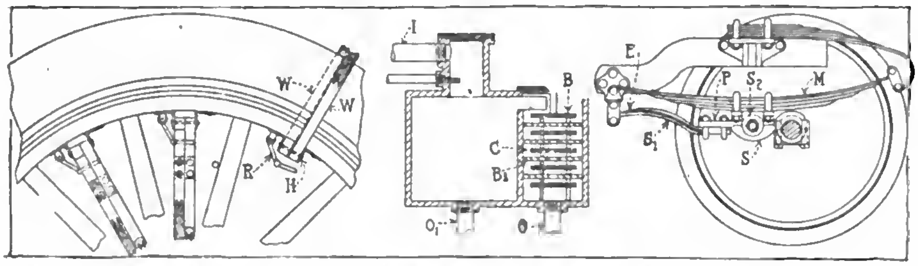


Fig. 1—Thiesen anti-skidding device. Fig. 2—Still muffler. Fig. 3—Neuberth spring suspension

No. 1,048,435—to Vernon B. Still, Patchogue, L. I., N. Y. Granted December 24, 1912; filed April 4, 1912.

Automobile Spring Suspension—Consisting of a small elliptical spring supplemental to the main spring in its action.

The spring described in this patent has the purpose of assisting the main elliptical suspension spring of the car in its work and also to serve as a rebound check, being adapted to compensate for excessive deformation of the main spring. It consists of a leaf spring, S1, attached to the end of a plate, P, which is formed by the free end of a saddle, S, the latter being secured to the axle of the car. The spring S1 projects beyond the plate P, and with the saddle S forms a lever having a gradual resiliency toward its outer end, E, which is secured to the body of the car. It may be noted in Fig. 3 that saddle S and spring S1 are of approximately the same length. A main spring, M, is secured at its ends to the car body and is supported at the center by a saddle, S2, which is arranged equidistantly between the axle and the supplemental leaf spring S1.

No. 1,048,336—to George E. Neuberth, Newark, N. J. Granted December 24, 1912; filed October 10, 1910.

Incandescent Headlight Lamp—Consisting of two filaments contained in the same bulb.

In Fig. 4 the headlight idea described in this patent is illustrated, the lamp consisting of a parabolic reflector and a bulb, B, mounted in its apex. In the bulb, which has two bases, B1 and B2, two filaments, F1 and F2, are contained, the former of which is located practically in the focal point of the parabolic reflector, while F2 is farther from the apex than this point. The rays of the filament F1 produce a beam of light parallel as it emanates from the reflector, while the shadow formed in this beam by the base B2 is dissolved by the intersecting rays of the filament F2, which is out of focus with respect to the parabolic reflector.

No. 1,048,017—to Theodore A. Willard, Cleveland, O. Granted December 24, 1912; filed February 9, 1910.

Tire-Patching Device—Consisting of bracing means for keeping a tire in place on a wheel-shaped carrier while it is being repaired.

This patent describes a tire-patching device, Fig. 5, comprising a flanged rim, R, on which a tire, T, is mounted, a flexible patching strap, P, extending across the tread portion of the tire. To one extremity of the strap a bar, B, is secured which rests on the outer extremity of the rim flange; a hook member, H, passes through the bar and engages one rim flange. The other end of the strap is secured at S to the rim.

No. 1,048,189—to Gustave J. Martel, Chicago, Ill. Granted December 24, 1912; filed July 21, 1911.

Internal-Combustion Engine—In which each working cylinder works in parallel with a pumping cylinder.

Fig. 6 shows the subject matter of this patent. The engine described in this patent consists in its simplest form of a working cylinder, C, and a pumping cylinder C1. A piston P is mounted in the working cylinder which compresses an explosive mixture at the end of each stroke, which mixture is exploded to impart reciprocating movement to the piston. The cylinder C has centrally disposed intake and outlet ports Q1. A pumping piston, P1, in the cylinder C1 is moved in the same sense and at the same speed as P. A carbureter is also mentioned in this patent, and a cylindrical casing, C2, is in place between it and the cylinder C1. A valve mechanism in this casing controls the admission of mixture to the two inlet ports located in the ends of the cylinder C1. Another casing between C1 and C regulates the passage of mixture from the former to the latter cylinder, the control mechanism consisting, in both cases, of a slightly tapered rotary valve having two oppositely disposed, superimposed ports making communication between proper passages in the casing to regulate admission and exhaust. This construction makes possible the working of the engine on the two-stroke cycle and without the use of poppet valves, insuring a plain and efficient combustion chamber.

No. 1,048,095—to Ralph Tagan, Atlanta, Ga. Granted December 24, 1912; filed July 24, 1911.

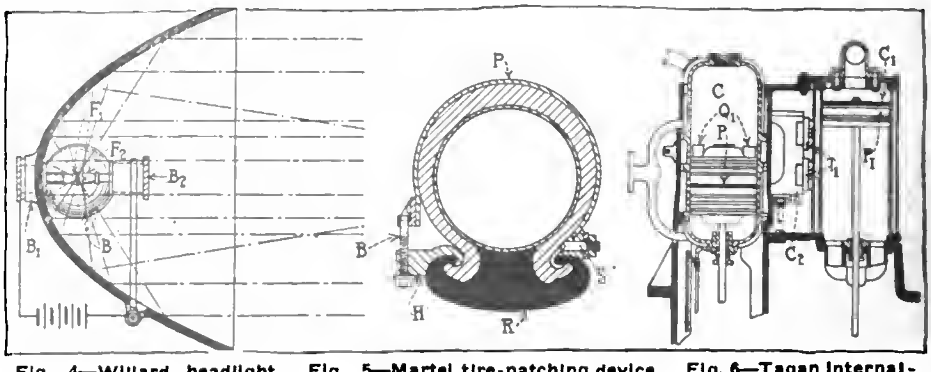

Fig. 4—Willard headlight. Fig. 5—Martel tire-patching device. Fig. 6—Tagan internal-combustion engine

VOL. XXVIII NEW YORK—THURSDAY, January 9, 1913—CHICAGO No. 2

The AUTOMOBILE

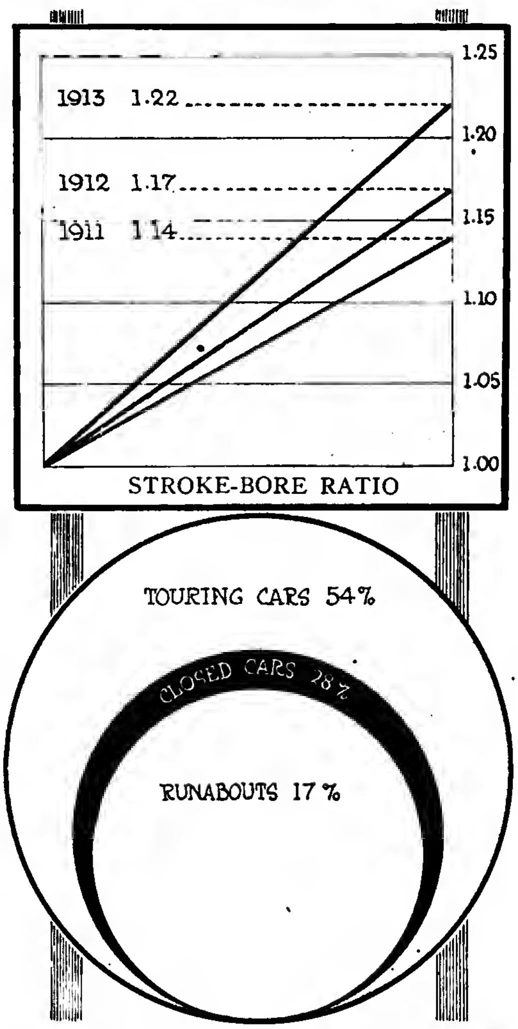
An Analysis of the 1913 Car

Survey of Entire American Automobile Industry Reveals Growth — Six-Cylinder Car Big Gainer—Horsepower Slightly Reduced and Stroke Lengthened—Engine Starters and Electric Lighting Are Features—Prices Are Higher

THE national automobile shows which open in Madison Square Garden and Grand Central Palace in this city on Saturday, January 11, will give the waiting public its first opportunity of viewing as a unit the 1913 models. In the Garden will be forty-three makes exhibited, in the Palace are forty-six, making a show total of eighty-nine. The buyer, in real earnest to survey the entire car field, can see ten other different makes along the Broadway salesrooms, thus having a field of 100 different makes to satiate his fastidious whims.

But though there is a round hundred laid at his feet, he then sees but a fraction of the enormous passenger car industry for there are sixty other makers of reputation who are neither at the shows nor represented along Broadway. Having the passenger vehicle shows held simultaneously in the two buildings for the first week and the commercial vehicle exhibits in the same arenas on the second week, with accessories present both weeks, affords a feast of showdom rarely if ever before afforded an American citizen.

Before in anywise endeavoring to analyze the broad field of automobile progress during the past year, look for a moment at what choice the purchaser has before him. The field is scarcely so broad as last year. At the start of 1912 there were 366 different chassis models to select from, and with the various bodies for each gave a possible field of 805 different body models. This year there are fewer chassis listed. To be exact, the number is 339, or a reduction of twenty-seven, due to the elimination of certain concerns by financial troubles followed by court action, and also to other concerns reducing the number of models they are marketing in order to cut down manufacturing cost and increase production. In the newcomer ranks are Edwards, Henderson and Touraine. Among those not now in existence, but familiar faces in the past are Elmore, Thomas,



Average stroke-bore ratio increases—Popular favor still turns to the touring car, with closed cars second

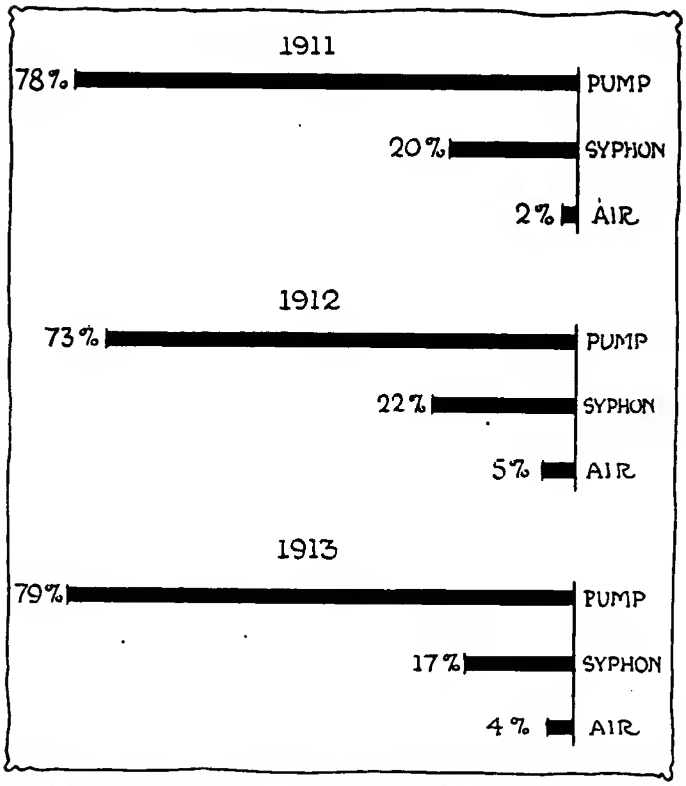
This chart tells the story of the growth of six-cylinder motors during 1911 and 1912 and the relative standing in 1913



Water pump circulation decreased slightly last year, but is now at its zenith

Marquette, Brush and a few others of less national reputation.

To the buyer who is interested in what he is going to get for the amount of money he has to spend, the question of price is paramount, and, in a nutshell, prices are higher than a year ago. Over half of the cars listed are higher priced than on January 1, 1912, due largely to more equipment in the way of engine starters, electric lights, tops, windshields, demountable rims, speedometers, anti-skid provisions, shock-absorbers and other equipment. The net result is more money's worth to the buyer, although his initial outlay is larger. The greater equipment is more noticeable among the cars listing at $2,500 and over, as generally those selling under this price were mostly sold with full equipment, the equipment being one of the inducements to the buyer.

The increase in price ranges from $50 to $500, but actual statistics, based on all of the listed models last year and those listed for this season, show the average price for 1912 at $2,508 and the average price for 1913 at $2,585, an increase of $77. This figure is based on the listed models and does not take the output into consideration. Were the average based on the actual cars sold it would be very much lower than this price mark.

But all have not raised the price. There are many examples of reduction, these ranging from $500 down. Where reductions are made they are largely attributed to reduced cost of production due to larger output, or to the reduction in the number of models, or to the redesigning of parts permitting of simpler manufacture and of using the parts in different models.

There are not a few cases where the prices of 1912 become the prices of 1913 and yet engine starters, electric lighting and more equipment are added. There are a few instances where the equipment has been added and the price cut from last year's figures.

Yet in spite of fewer models and higher prices, the buyer has a wide field to select from. If he desires a runabout there are 138 models listed to whet his appetite; if his tastes turn to five-passenger touring cars he has a selection field of 325; in the seven-passenger tourist field there are 100 models; the coupé division offers a latitude of 54; and in the limousines, landaulets and single-compartment vehicles there is a field of 174 to choose from. What more could be desired?

The following will be shown in their New York showrooms during the double exhibition: Apperson, Colby, Correja, Ford, G. J. G., Touraine, Palmer-Singer, Simplex, Staver and Warren.

Those that will not be seen in the show nor along Broadway include the following:

Ames, Amplex, Arbenz, Atlas, Austin, Burg, California, Cameron, Carhartt, Carroll, Chadwick, Cino, Coey, Corbitt, Crane, Crawford, Crow-Elkhart, Croxton, Day, Diamond T, Dispatch, Dorris, Duryea, Duquesne, Enger, Falcar, Great Eagle, Gleason, Glide, Great Southern, Great Western, Grout, Halladay, Holly, Indiana, Lambert, Lexington, Lion, Luverne, McFarlan, McIntyre, Mason, Motorette, Midland, Morse, Miller, Nyberg, Omaha, Pratt-Elkhart, Pilot, Pertex, Reeves, Richmond, Rayfield, Schlosser, Spaulding, Spoerer, Triumph and Zimmerman.

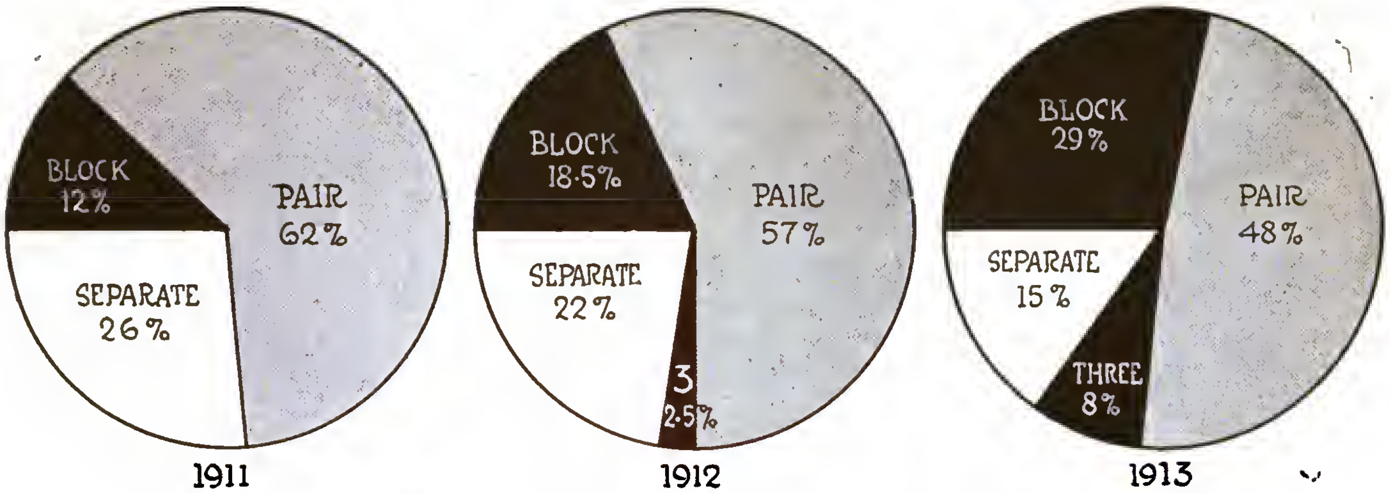
Coming to a consideration of the various chassis types for this year, and comparing them with previous years in order to note the direction of progress, many unmistakable currents of tendency are observed. Everybody is talking bore-stroke ratio, that is, the ratio of the piston stroke to the cylinder bore. In these days with a leaning towards long strokes this argument is perhaps more used by the salesman than any other. The bore-stroke ratio is 1.2 to 1, that is, on an average of all the American listed chassis the stroke exceeds the bore by 22 per cent. Last year the ratio was 1.16 to 1 and the year before 1.14 to 1.

Three Years of Stroke-Bore Ratio

1911, 1.14 to 1 1912, 1.16 to 1 1913, 1.22 to 1

These figures show an unmistakable movement, and while the stroke has been increasing, the bore has been diminishing. Figures covering these three years for motors with a stroke in excess of the bore, for motors with stroke equal to the bore, and for motors with a stroke less than the bore are:

	1911	1912	1913
Stroke greater than bore	219	306	314
Stroke equals bore	44	36	18
Stroke less than bore	17	24	7



The steady growth of block castings is one of the major characteristics of motor tendencies for the past two years

When reduced to percentage these figures show that in 1911 78.2 per cent. were of the longer-stroke type; in 1912 83.6 were of the longer-stroke type, and in 1913 93.1 are of the longer-stroke type. These figures are graphically charted on these pages.

Next of importance to stroke-bore ratio in motor design for this year is the strong leaning towards six-cylinder construction. There are not fewer than seventy-six concerns listing six-cylinder models, these companies having in all 120 different chassis models. Of this number there are thirty building nothing but sixes, some of them building one model, some two, and others three, four and five. Here are the names:

A. E. C.	2	Holly	1	Oldsmobile	2
Austin	3	Inter-State	1	Packard	5
Burg	2	Keeton	1	Palmer-Singer	2
Chadwick	2	Lexington	1	Pierce-Arrow	4
Chevrolet	1	Lozier	2	Premier	2
Coey	1	Luverne	1	Rayfield	1
Crane	1	Matheson	1	Speedwell	1
Flanders	2	McFarlan	3	Stevens-Duryea	2
Garford	2	McIntyre	2	Touraine	3
Havers	2	Norwalk	3	Winton	1

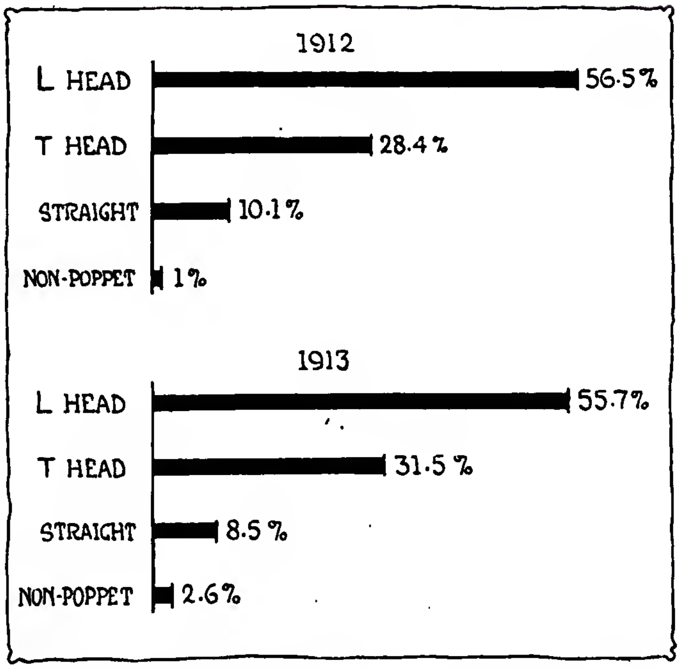
In this list are many new names which will be readily detected by those who are following the development of the art from year to year. Among these new six-cylinder faces are Stearns-Knight, Marmon, Stutz, Auburn, Moon, Norwalk, Touraine, Oakland, Speedwell, Studebaker, Staver, Warren, Westcott, Herreshoff, Hudson, Inter-State, Jackson, Cole, Colby, Chevrolet, McIntyre, Nyberg, Republic, Zimmerman, Croxton, Firestone-Columbus, Lenox, Lexington, Keeton, Holly, Duquesne, Crow-Elkhart, Correja, Crane, Burg, Alpena, Carroll, A. E. B., Luverne and Motza.

While these concerns have made their début into the field, the older concerns in the six-cylinder ranks have been adding to its numbers by introducing more models. For example, Packard, Locomobile, Lozier, Premier, Knox and others have added small sixes. There will be undoubtedly more of these additions announced before the show circuit is closed.

The growth of the six-cylinder field is largely an outcome of the public demand for sixes, which has been created by the able pioneering work done by a half dozen of our concerns which placed their entire confidence in six-cylinder types 3 and 4 years ago, and have been building them in many cases exclusively ever since. In this connection must be mentioned such concerns as Winton, Stevens-Duryea, Pierce-Arrow, Peerless, Franklin, Knox, etc.

The growth of the six-cylinder car during the last two seasons is well shown by the following figures, which show the number of two-cylinder, four-cylinder and six-cylinder chassis listed. Here they are, with percentages:

	1911	1912	1913
Six-cylinder chassis	32—11.4	60—16.4	120—35.4
Four-cylinder chassis	239—85.3	293—80	211—62.7
Two-cylinder chassis	9— 3.2	9— 2.4	7— 2



L-type cylinder casting is gradually losing ground and T-head type making slow gains

When viewed on a percentage basis, it will be seen how the six has gradually risen in regular steps from 11.4 per cent. in 1911 to 16.4 last year, and then with one broad leap to 35.4 this season. While this progress upward has been on hand, the percentage of four-cylinder models has gradually dropped in these three seasons, as the following figures show: 85.3 per cent., 80 per cent., 62 per cent.

The horsepower of the six-cylinder model in America averages higher than that for Europe, as might be expected, but there is a gradual reduction taking place from year to year, so that soon the American six-cylinder will be as low in horsepower as the foreign type, or nearly so. The poorer American roads and the heavier bodies call for additional horsepower, but with road improvements, increased motor efficiency and eliminating needless body weight, there is no reason why the next few years will not witness gradual steps downward in power.

Last year the average horsepower of the listed six-cylinder chassis was 45.77; this year it is 41.24, a reduction of 11 per cent. This is not all accounted for by longer stroke and reduced bore, because the piston displacement averages lower. Last year it was 474.4 cubic inches; this year it is 435.3. But yet with this reduction we are larger than the English six, which in

1912 averaged 34.7 horsepower and this year has risen to 36.8. In France, where the small motor is the giant of the day so far as activity is concerned, the average horsepower was 30.7 last year and it is cut to 26.6 this year.

In considering the style of casting used on four and six-cylinder motors, the T-head design is gaining. Last year its following numbered 28.4 per cent. of the total; this year it is 31.5, and during the same time L-head construction has fallen from 56.5 to 55.7. The valve-in-the-head type is diminishing. Last year thirty-seven models were listed; this year there are but twenty-nine. Last year saw four non-poppet models; this year there are nine, this increase being due to Stearns adding another Knight type, the Edwards company bringing out new Knight models. Speedwell adopting the Mead design, etc. The tabulation of cylinder types used and the percentage standing of each for this year and last is as follows:

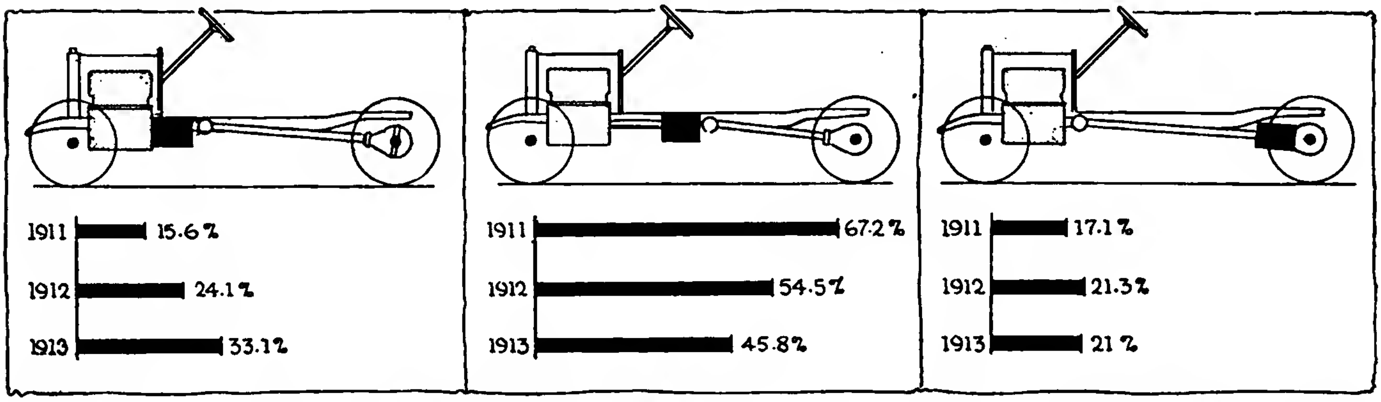
	1913 Per Cent.	1912 Per Cent.
T-head cylinder design	104—28.4	107—31.8
L-head cylinder design	207—56.5	189—55.7
Valve-in-head design	37—10.1	29— 8.5
Non-poppet design	4—1	9— 2.6

ferences in this respect. Fiat, for example, has a four-cylinder block with 557 cubic inches displacement, and a six with 556 cubic inches. These are the largest block types listed. The White six has 489.4 cubic inches displacement, the Staver six 452.4, the McFarlan the same, the Case measures 420.9. Others over the 400 mark are Only, 446.8; Pilot, 452.4; Cino, 452.4, and Westcott, 452.4.

The baby block is the new Studebaker, 154.8 cubic inches, with bore of 3.8 to 6.2 and stroke of 3.75 inches. Others in this low-capacity displacement class are Herreshoff, 161; Ford, 176; Krit, 176; Detroiter, 170; S. G. V., 193; R. C. H., 165.9; Paige, 170.7; Oakland, 192, and Metz, 176. The others range between the 200 and 400 marks.

Thermo-syphon cooling has dropped very considerably as compared with last year. In 1911 it was increasing, 1912 marked a gain and this year a slight drop. Here are the figures:

	1911	1912	1913
Water pump circulation	217—77.5	266—73	266—78.9
Thermo-syphon circulation	57—20.3	80—22	58—17.2
Air-cooling	6— 2.1	19— 5	13— 3.8



Mounting gearbox as unit with motor has gained 15 per cent. in last two years; mounting amidship has lost; and rear axle units remain stationary

Last year saw twelve different models of two-cycle engines listed, and for this year there are but five, due to the discontinuance of the Elmore and the Amplex being changed to four-cycle type.

With this trend in the matter of cylinder design there moves hand in hand the amazing landslide towards monobloc castings. This type of casting for four and six-cylinders has grown in leaps and bounds. There are sixteen concerns manufacturing six-cylinder block types of motors. They are: White, Fiat, Flanders, Garford, Studebaker, Warren, Inter-State, Herreshoff, Staver, McFarlan, McIntyre, Pilot, Keeton, Cino, Duquesne and N. E. C.

Statistics show that the block type of casting has grown from thirty-four in 1911 to sixty-seven in 1912 and to ninety-six this year. Here are the figures on the different methods of casting:

	1911	1912	1913
Cylinders cast in block	34	67	96
Cylinders cast in pairs	171	207	163
Cylinders cast in threes	...	9	27
Cylinders cast separately	72	82	51

When these figures are reduced to percentages, they show a steady reduction in the casting in pairs, the downward steps being 61.7 per cent., 56 per cent. and 48.3 per cent. There has been a steady reduction in casting separately as follows: 26 per cent., 22.4 per cent. and 15.1 per cent. The increase in block castings has been regular, namely, 12.2 per cent., 18.35 per cent. and 28.4 per cent. When block-motor castings were first introduced it was generally rumored that cylinder sizes would have to be kept especially low. Figures show, however, that there are wide dif-

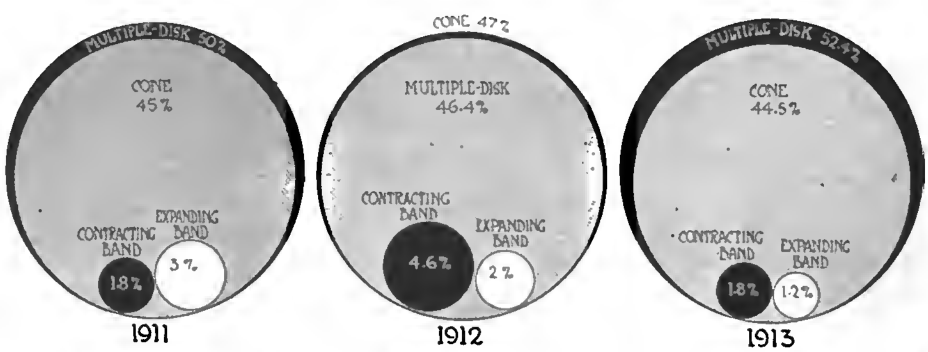
Dual ignition is still the popular hero, with a following of 234 models as compared with fifty-one using single ignition and fifty using double.

Much interest has been created of late in the method of mounting the gearbox so far as location is concerned. There are three divisions, those locating it as a unit with the motor, those mounting it as a separate unit, in the middle of the chassis, and those making it as a part of the rear axle. The rear-axle method is holding its own, mounting it as a unit with the motor is steadily increasing, and mounting it separately under the chassis is constantly falling off. The figures show:

	1911	1912	1913
Gearbox unit with motor	42—15.6	88—24.1	107—33.1
Gearbox separate amidships	181—67.2	199—54.5	148—45.8
Gearbox unit with rear axle	46—17.1	78—21.3	68—21

In these tables the actual number of models employing the different styles of gearset, as well as percentages of the total, are given. The trend is better shown by the per cent.

The four-speed gearbox is increasing in use; the three-speed



Multiple-disk clutches have gained in popularity and are now leading the pioneer cone type by a slight margin

set is holding its own; the two-speed set is decreasing; the friction set is decreasing. Statistics show as follows:

	1911	1912	1913
Four-speed gearset	50—17.8	66—18.2	76—22.4
Three-speed gearset	200—71.4	267—72.9	245—72.2
Two-speed gearset	18— 6.4	19— 5.1	9— 2.6
Friction transmission	12— 4.2	14— 3.8	9— 2.6

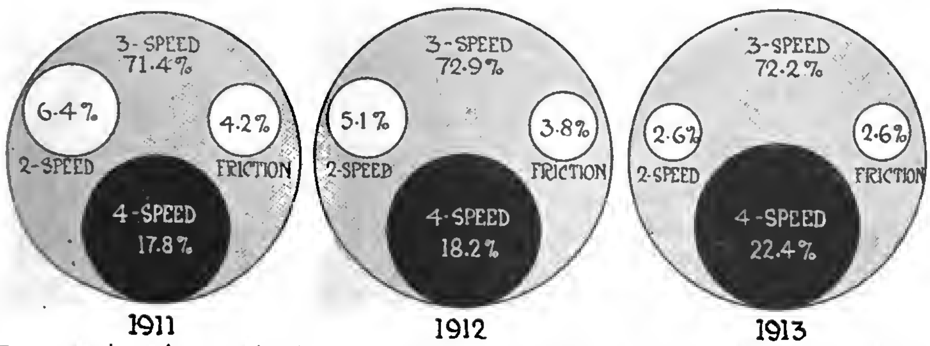
Space does not permit to go into detail in the question of clutches, which is a close contest between the multiple disk and the cone, with the disk a leader at 52 per cent. compared with 44 per cent. of the cone. Contracting band types and also expanding types have a following of less than 2 per cent. each.

It is all shaft drive when the question of final transmission is considered, so far as proportions are concerned, yet there are six companies listing worm reduction in the rear axle, three of which furnish it as an option. Those regularly listing worm drive are Edwards-Knight, Keeton and Holly. Firestone-Columbus, Pathfinder and Cino give it as an option.

The use of chain drive for camshafts, magneto shafts and pump shafts has grown. True, the growth has not been anything like what was anticipated, which, as one maker has put it, has been largely due to questions of manufacture. The American maker is favorable to fitting American-made chains for this work, and now that domestic products giving entire satisfaction are on the market it is certain that a rapid growth will be made. Thirteen companies fit silent chains, there being in all twenty-two models manufactured by these concerns. The companies and the number of models are:

Stearns, five; Velie, three; Kissel, four, and the following one each: Cadillac, Jackson, Oakland, Hupmobile, Edwards, Columbia, Stoddard-Dayton, Paige, Rayfield and Atlas.

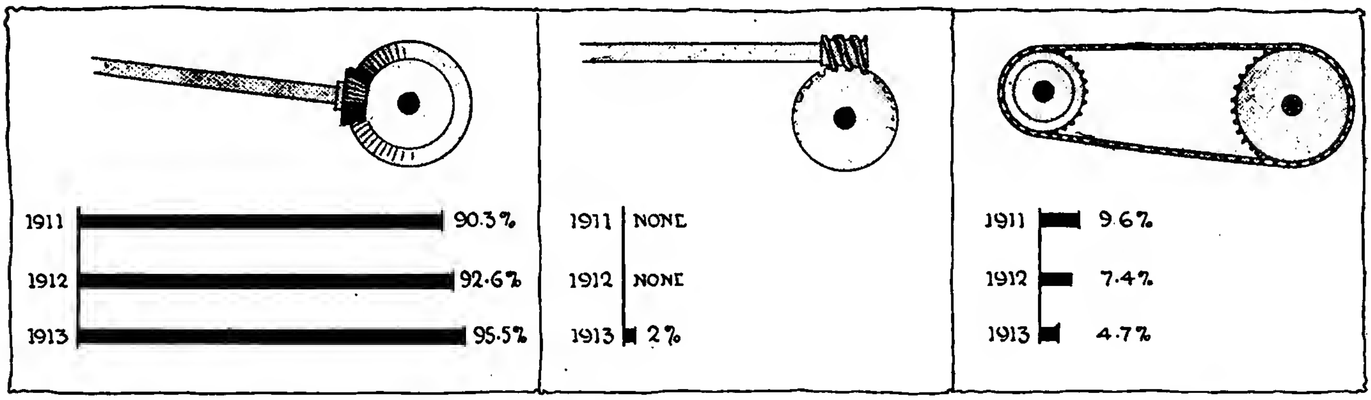
Fitting the steering column on the left side has made more than anticipated gains. At one time the feeling was that there would be a landslide towards this construction. The progress has been slower than looked for. Today eighty-five companies list left-hand control, 238 list right-hand control, twelve give an option, and four list center. It is easier to remember these in percentages: Right hand, 70; left hand, 25; optional, 3; center, 1.



Four-speed gearboxes make steady gains, while three-speed sets, which lead, remain stationary; friction sets decreasing

A wide change has come over the engine starter field within the last year in that the explosive gas type, which was a leader last season, is now in second place, and the premier position is held by the electric type, which controls 69 per cent. of the field. The explosive gas type is second with a following of 15 per cent., the air type is third with 11 per cent, and last comes the mechanical or spring type with 3 per cent following.

The advent of electric lights has greatly aided in the introduction of the electric starter, and from the avidity with which it has been taken it would seem that the public had been patiently waiting, and when the moment arrived received the electric type with open arms. The electric starter is present in a variety of forms, which for convenience may be designated single-unit systems and double-unit ones. There are types which act in unison with the electric lighting and also the ignition system, such an outfit really being a triple-service one. There are others in which one unit serves for starting and lighting; there are those where there is a single motor for starting; then, again, some systems are on the market in which two units are needed for starting, one a motor to crank the gasoline engine and the other a generator to charge the battery.



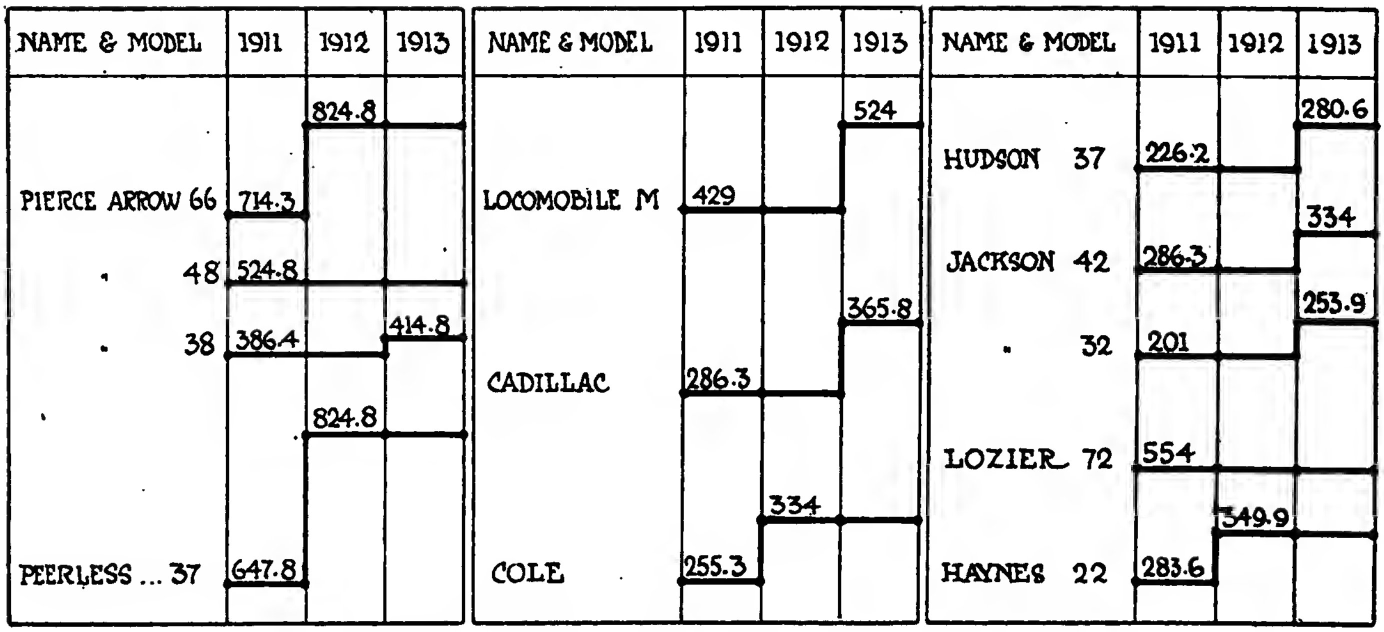
Bevel drive, which predominates the field, is gaining steadily; chain is losing slowly; worm makes its appearance

The flywheel type, that is the one in which the starting motor is incorporated in the flywheel, has made considerable progress. With this type as well as with others in which the motor or motor-generator are located alongside of the gasoline motor the one great aim is the reduction of weight and a keen business rivalry has developed on this line alone.

Many of the engine starters look the part of appurtenances, rather than forming an integral portion of the motor, a condition to be expected due to the rapid advent of the electric type, but which abuse, if it may be so termed, will be corrected before another year, so that the starting units will look as much a part of the gasoline motor as the carbureter or magneto.

Air starters have a good following. There has been a tendency, where they are used, to fit air pumps on the motor for generating the necessary air pressure, which has added to the expense to the extent of the pump, which is not mounted on the motor in every case, but often is grouped with the gearbox and driven from one of its shafts. Where air pumps are used they are more carefully made than last year.

The year has been an active one in the carbureter field, and while the vast majority of the carbureter business is carried on by car building companies, rather than by car building companies, it is nevertheless a fact that car makers are vitally interested in it. As the carbureter field is covered at some length in other pages of this issue, it is unnecessary to comment at length at this



Showing changes made in the piston displacement in some models in the last 2 years

time further than to state that the movement towards multiple-jet construction is gradually developing and there has been wide effort to add easy-starting devices whereby gasoline can be by-passed direct from the float chamber to the manifold above the throttle in order to get the necessary richness. Added to such arrangements are hot water or air jackets and hot-air horns connecting with the exhaust manifold. Those using auxiliary air valves have added improvements to secure more ready and accurate adjustment and more steady action.

The strong movement towards placing the steering wheel on the left side of the car, which was begun a year ago, has shown a marked increase and while right-side control still is a big leader, the left-hand argument has a 25 per cent. following, leaving right-hand with 70 and the remaining 5 per cent. divided between those giving an option and those placing it in the center. By count of 339 chassis listed in the tabulations in other pages of this issue, 238 fit the steering wheel on the right-hand side, eighty-five place it on the left side, twelve give an option and four mount it in the center.

The one-time argument that only low and medium-priced cars would have the wheel mounted on the left is quite exploded by the fact that some of the highest-priced makers have placed the wheel on the left side on new and smaller models that they have recently added to their lines. In this respect attention is directed to the new Packard six, White six and fours, Lozier, Marmon, Premier, National, etc. Among the concerns listing left-side steering are: Maxwell, Michigan, Midland, Mitchell, Moon, Metz, National, Nyberg, Packard, Paige, Peerless, Premier, R. C. H., Reo, Republic, Schacht, Spaulding, Speedwell, Staver, Stoddard, Velie, White, Ames, Atlas, Austin, Chevrolet, Correja, Croxton, Cunningham, Day, Detroiter, Duquesne, Edwards, Firestone-Columbus, Ford, Garford, Glide, Great Southern, Henderson, Herreshoff, Holly, Inter-State, Keeton, King, Krit, Lenox, Lexington, Lion, Lozier, Luverne and Marmon. Of these some list all with left-side wheel, others with one, some with two and some with three models.

There is little new in frame construction, the conventional dropped frame being in the ascendency. The double-drop has gained in following but not to the extent that might be anticipated. The underslinging of springs, that is, clipping them under the axle instead of above the axle, has worked against the double-dropped frame in that it allows of a considerable lower body support, without the added expense of the double-dropped side members. The three-quarter elliptic spring has gained during the year, in spite of the fact that some of its old followers in Europe have discarded it and returned to the semi-elliptic type in order to eliminate side sway of the body.

More concerns than ever before are equipping their cars with shock-absorbers as stock. This suggests the more abundant equipment that nearly all of the cars are being listed with for this season. Concerns that heretofore scoffed at selling with equipment have gone through the entire gamut in adding such necessaries as top, windshield, speedometer, demountable rims, self-starter, etc., and often without adding to the price and in one case the price has been reduced. The movement of the full-equipped car of a few years ago has had a strong influence on the buyer and has virtually forced the higher-priced maker to deliver his car ready for the roads and any kind of weather.

There is no doubt that the question of prices of the 1913 models will at first present to the average layman the idea that there has been an increase in prices generally, due to the higher list prices than were quoted on 1912 models. This is not the case, however. An arbitrary comparison of the list prices of 2 years is no criterion to go by. The question resolves itself down to this: What did the equipment of the car consist of last year as compared with this? The problem of equipment has been taken care of, by including the equipment at an inclusive price. One of the prime movers, in the price increase, is traced to the self-starter and lighting dynamo. In other cases, the model, although of approximately the same rated horsepower in both years, may have an entirely new rear axle and many other improvements such as increased wheelbase or larger tires. It will be found that after adding what it would actually cost to include the extras, and then place the total alongside the price of the 1913 model, that the 1913 model is really cheaper.

There are other cases where the prices have actually been reduced. Where this practice prevails, it will invariably be found that large quantity production is the direct cause. This is true of the three Ford types, where a drop of $90 has been made in the case of the touring car, $100 on the town car and $65 on the runabout. The Overland 71 is another example in which there is an actual drop of $25. But this does not represent by any means the actual saving to the buyer. The new model includes top, windshield, speedometer, acetylene gas tank, tire irons and crankless starter, besides an elongation of the wheelbase. The Cole model 50 was marketed last year without equipment at $1,885, and when the equipment that is included in this year's models was added, the price was increased to $2,060. The price of this year's model is $1,985 showing a *prima-facie* saving of $75. In addition to the equipment a stronger axle has been incorporated as well as a new radiator. The Delco lighting, starting and combined ignition system has also been added, which materially increases the price value of the car.

Due to an increased output, the Chalmers six-cylinder car has been reduced from $3,250 to $2,400 for the two, four and five-passenger cars and to $2,600 for the seven-seater. The other Chalmers model, while showing an actual increase in price from $1,900 to $1,950, has had a Gray & Davis lighting dynamo added, thereby virtually reducing the selling price.

Two further examples of actual price reduction are to be found in the Fiat and Packard models for next year. The Fiat company has made a clean-cut of $500 on the four-cylinder 35 and six-cylinder 50 models, besides including about $300 worth of equipment in the reduced price that was charged for extra last year. The reduction in price in this instance is due to the better and larger manufacturing facilities of the American factory. The Packard Company has reduced the price of the six-cylinder, 48-horsepower touring car from $5,000 to $4,850.

The accompanying table shows clearly that the majority of makers have a higher selling price this year than last. As has already been explained, this increase must not be regarded as such without further investigation into the cause. An excellent example of this is to be found in the 1913 Cadillac. Last year's model sold for $1,800 and the 1913 model is listed at $1,975, showing an increase of $175. Last year's model did not include a top, windshield or demountable rims which, when ordered extra as they usually are, would cost the purchaser $185, in itself alone more than the extra cost of the new 1913 model in which these extras are included. In addition the motor has been given 1.25 inches more bore, adding materially to the power, the wheelbase has been lengthened from 116 to 120 inches, the 4-inch tires have been increased to 4.5-inches, and a more expensive speedometer and a cocoanut mat have been added. It is only by analyzing the car in this manner that the buyer can form a correct idea and commensurate their values.

It would be manifestly unfair to compare the price of the last year's Hudson, for instance, with this year's model 37, the price of last year's being $1,600 against $1,870 this year. In the first place, the motor has been entirely changed, as well as several other structural features. Besides, a Delco starter and lighting outfit have been added including electric lights.

The tabulation given herewith has been compiled rather to show the tendency for next year than to attempt to set forth a complete list of the price changes that have been made. Consequently the figures cannot be taken as a means of striking a general average of increase in list price.

Quite a large number of the cars that list over $3,000 have remained at the same price, despite the fact that many have added equipment. Among those who have reduced their prices in this class may be mentioned the Haynes, Palmer-Singer and Premier. The Franklin prices have advanced $100, the extra price including an Entz self-starter and lighting system as well as a speedometer. The Kissel models have advanced $150, due to the addition of a self-starter and electric lighting system. The same remarks apply to the Matheson who have added a Westinghouse self-starter and electric lighting system, leaving the chassis materially the same as last year. The two larger models of the Pierce-Arrow have not been altered in price, while the smallest, namely, the six-cylinder 38 horsepower, has been increased by $300. This is due to the change in the size of the motor and the addition of an electric-lighting system and self-starter.

Both the White models that sell for more than $3,000, namely, the GE and GF, the latter being the six-cylinder, have not changed as far as price is concerned, but in addition to last year's equipment, an electric self-starter and lighting system have been incorporated besides the addition of a Klaxon horn.

In the $2,000-to-$3,000 class, the general advance seems to be between $100 to $200 to take care of the self-starters and electric lighting outfits that have been added. The National company has increased its list price on this account by $150. This also applies to the Haynes, Kissel, Marmon, Mercer. There are some, however, that have increased the price $250; but when the added equipment is taken into consideration, it is seen that there is no increase in price, without some compensating reason.

Table Showing Changes of Price on Some 1913 Models Giving the Amount of Increase or Decrease

CARS SELLING FOR $3000 AND UPWARDS

Make	Model	1912	1913	Increase or Decrease
Abbott-Detroit	Limousine	$3050	$3000	—$50
Alco	Touring	6000	6000	Same

Stroke vs Bore

America - 1.22
France - - 1.65
Gt. Britain - 1.43

Installment I

¶ American motors show a tremendous majority of long stroke designs, 96.5 per cent. of all power plants being of this type. This article limits itself to a statistical review of this most important situation.

¶ In this installment American and French motors are dealt with, and a concluding installment to appear soon will contain a review of the British situation.

OUT of 280 American motors for this year, 272 have strokes which are longer than the bores; four are square, with bores and strokes the same; and four have shorter strokes than bores. The average stroke-bore ratio is .22:1, as compared with 1.16:1 last year and 1.14:1 in 1911. The long bore-stroke ratio for 1913 varies from 1.02 to 1.85, the various ratios being distributed as shown in the tabulation further down in this column. The latter indicates that 159.3 per cent., have a ratio between 1.10 and 1.30:1.

Stroke-bore ratios of American motors

From 1.00:1 to 1.10:1	31
From 1.11:1 to 1.20:1	84
From 1.21:1 to 1.30:1	82
From 1.31:1 to 1.40:1	36
From 1.41:1 to 1.50:1	23
From 1.51:1 to 1.60:1	6
From 1.61:1 to 1.85:1	3
Square Motors (1:1)	10
Short-stroke (1:>1)	5

Before considering American long-stroke motors individually it is proposed to draw a parallel between the long-stroke tendency as evidenced in this country and on the other side of the Atlantic. The triple chart shown on the bottom of this page illustrates the average stroke-bore ratios as they have obtained during the past 3 years in the manufacture of automobiles in the United States and Great Britain, that of France being given only for the past 2 years, but being sufficient to illustrate

Average stroke-bore ratios of American, English and French automobile motors, illustrating the increase of the ratio during the past 3 years and showing the remarkable start established by French engineers in their productions the trend in that country. These illustrations show that France is the leader of the long-stroke idea. While in 1912 the average stroke-bore ratio of French motors was 1.60:1, the ratio for 1913 is 1.65:1. The significance of this high figure is that while French engineers were among the first to realize the advantages of a long-stroke motor they have had no reason to change their opinion during the past 2 years; but, rather, the experiences obtained with early long-stroke motors have been of such a nature to induce them to further increase the ratio of the cylinder dimensions. If France was the pioneer in this movement, England was the first follower, perhaps due to the proximity of the two countries. England in 1911 produced motors with an average stroke-bore ratio of 1.33:1, in 1912 the ratio advanced to 1.37:1 and in 1913 to 1.43:1, perhaps on account of greater conservatism of the English engineers as compared with their French colleagues. The dotted lines on the chart illustrate the rate at which the stroke-bore ratio has been growing during the past years and if any conclusion may be drawn from this information, the tendency has rather gained and may be expected to gain still during the next few years.

To illustrate in detail the trend in American design THE AUTOMOBILE has compiled the accompanying tabulation giving bore, stroke and ratios for the past 3 years, but including only such motors as are still on the market. While this tabulation is not claimed to be absolutely complete, it is so within a very narrow margin, so that the averages from it are practically exact.

The greatest increase in stroke-bore ratio during 1912 was made by the Oakland 35 and the Westcott 50, both cars having a ratio exceeding their last year's by 43 per cent. The Oakland car, which had a square motor in 1912, has now a long-stroke type with a ratio of 1.43:1, and the Westcott had 1.05:1 stroke-bore ratio for 1912 and uses a ratio of 1.5:1 for this year. The leadership of these two makes in long-stroke progress illustrates in the best manner possible the alertness of manufacturers of medium-priced American cars. Directly after Oakland and Westcott comes the Mitchell 7-6 with a bore-stroke ratio of 1.65 which had a ratio of 1.11:1 in 1912. Next is the Auburn 33, formerly a square motor, but now having a stroke-bore ratio of 1.40:1. The Mitchell 5-4 is next with a ratio increase of 31 per cent., the 1913 ratio being 1.54:1 as against 1.18:1 in the 2 preceding years. The Staver 35, which had a ratio of 1.11:1 in 1912, is now 1.50:1, an increase of 35 per cent. Two cars show a ratio increase of exactly 30 per cent. These are the Moon 39, which had a ratio of 1.11:1 last year and

the year before and which now is 1.44:1. The other motor is the Garford G 15; last year its stroke was only 23 per cent. longer than the bore, but for 1913 the ratio has been increased to 1.60, which gives the motor one of the highest ratios used in American practice today. An increase of 28 per cent. has taken place in the case of the Knox 46, which has been changed from a short-stroke to a long-stroke design during the year 1912. Instead of .95:1 the motor is now 1.20:1. A stroke-bore ratio increase of 27 per cent. is the record of the Cadillac, which was a square motor, but which now has a ratio of 1.27:1. The Speedwell car has undergone the same change.

An examination of the tabulation brings out many other increases ranging from 25 per cent. down to 10 and less. Among the motors included in this group are the White GEB and White GF, the Maxwell 4, Crawford, Crow-Elkhart, Flanders 40, Atlas 12, Lambert 40, and many others.

On the other hand a few companies have reduced the stroke-bore ratios of their product, and the most notable instance in this group is the Oldsmobile, which has now a ratio of 1.15:1 as compared with last year's of 1.50:1. The decrease in this case is equivalent to 23 per cent. The Motorette is now a square design, while last year it had a ratio of 1.16:1. The Auburn 37 has continued its development toward a low stroke-bore ratio by using the proportion 1.12:1 this year, after the 1912 ratio of 1.27:1, which in turn was considerably below that of the preceding year, namely, 1.54:1. Mason, Krit and Imperial are other examples of the same practice.

Coming to the stroke-bore ratios themselves, the highest value in this respect is that by the Only car, which continues its ratio of 1.85:1 from last year. The second greatest ratio is that of the Mitchell 7-6, namely, 1.65:1. The Lambert cars with a ratio of 1.62:1 is next, being followed by the Mitchell 5-6 and the Garford G15, both of which have strokes 60 per cent. greater than their respective bores.

The stroke-bore ratio which ranks next after these is 1.56:1, in the Austin 66 and 67. Then follow several motors with the ratio of 1.54:1, as the R. C. H. and the Mitchell 5-4. Five makes of cars use motors with a stroke-bore ratio of 1.50:1; these are the Cino 560, the Correja R and S, Pilot 60, Staver 65 and Westcott 50. The motors with ratios between 1.40 and 1.50:1 number about a score, while the majority of cars use ratios from 1.10 to 1.33:1.

The tabulations of French bores, strokes and ratios appearing on pages 72 and 76 afford an opportunity to compare the continental practice to that current in America. Out of 229 motors listed in this tabulation all but forty have stroke-bore ratios of more than 1.30:1 and of these forty twenty-seven ratios are higher than 1.20:1 Not a single short-stroke motor appears in the table, the minimum ratio being 1.07:1, this being the Germain motor. A Sizaire-Naudin motor with a ratio of 2.48:1 represents the most advanced step of the French designer in the direction of the long stroke. Next to it ranks the Gobron motor, which has a ratio of 2.19:1, the La Buire with a ratio of 2.18:1 and the Rossel, 2.12:1. There are fully thirteen motors with a ratio of 2.04:1, bringing the number of power plants in which the stroke is more than twice the bore beyond a score. Remembering that the American Only car with a ratio of 1.85 stands practically in a class by itself and that the next ratio is 1.65:1, it appears that the French school of automobile engineering, which has this year produced dozens of motors with ratios higher than 1.65:1, is far ahead of American practice in this point of design. The reason is probably that the advantages of long-stroke motors were reasoned out theoretically some time before practice verified the assumptions of their designers, and the French being so much greater theorists than Americans, gained an appreciable advantage over the latter, due to their energetic start in this contest of designs. The practical effect of this development is that the French average ratio of 1.65:1 is 35 per cent. higher than the American average of 1.22:1 and on a level with the ratio 1.65, which in a way may be considered as the American high-water mark in stroke-bore ratios.

Of the 229 French motors here tabulated, 201 are four-cylinder types and twenty-eight six-cylinder designs. The average stroke-bore ratio of the four-cylinder motors is 1.64:1 and that of the six-cylinder power plants 1.80, which is responsible for the general average being slightly higher than that of the four-cylinder motors.

The list of English cars for 1913 is much smaller in number than either that of American or French products, but nevertheless the progressive spirit of British designers has created in 1913 product with an average ratio, as mentioned above, of 1.43:1. In an early issue of THE AUTOMOBILE a list of English motors giving their bores, strokes and ratios will be published.

One of the chief differences between French and British designers is the favoring attitude of the latter toward six-cylinder designs. In France, twenty-eight out of 201 motors are six-cylinder types, or 12.2 per cent., as compared with 18.6 per cent. of the 113 English motors. The list of English motors not being published this week, only specific instances will be cited at present.

Cylinder Sizes and Ratios of Bores and Strokes of American Four and Six-Cylinder Automobile Motors for 1911, 1912, 1913

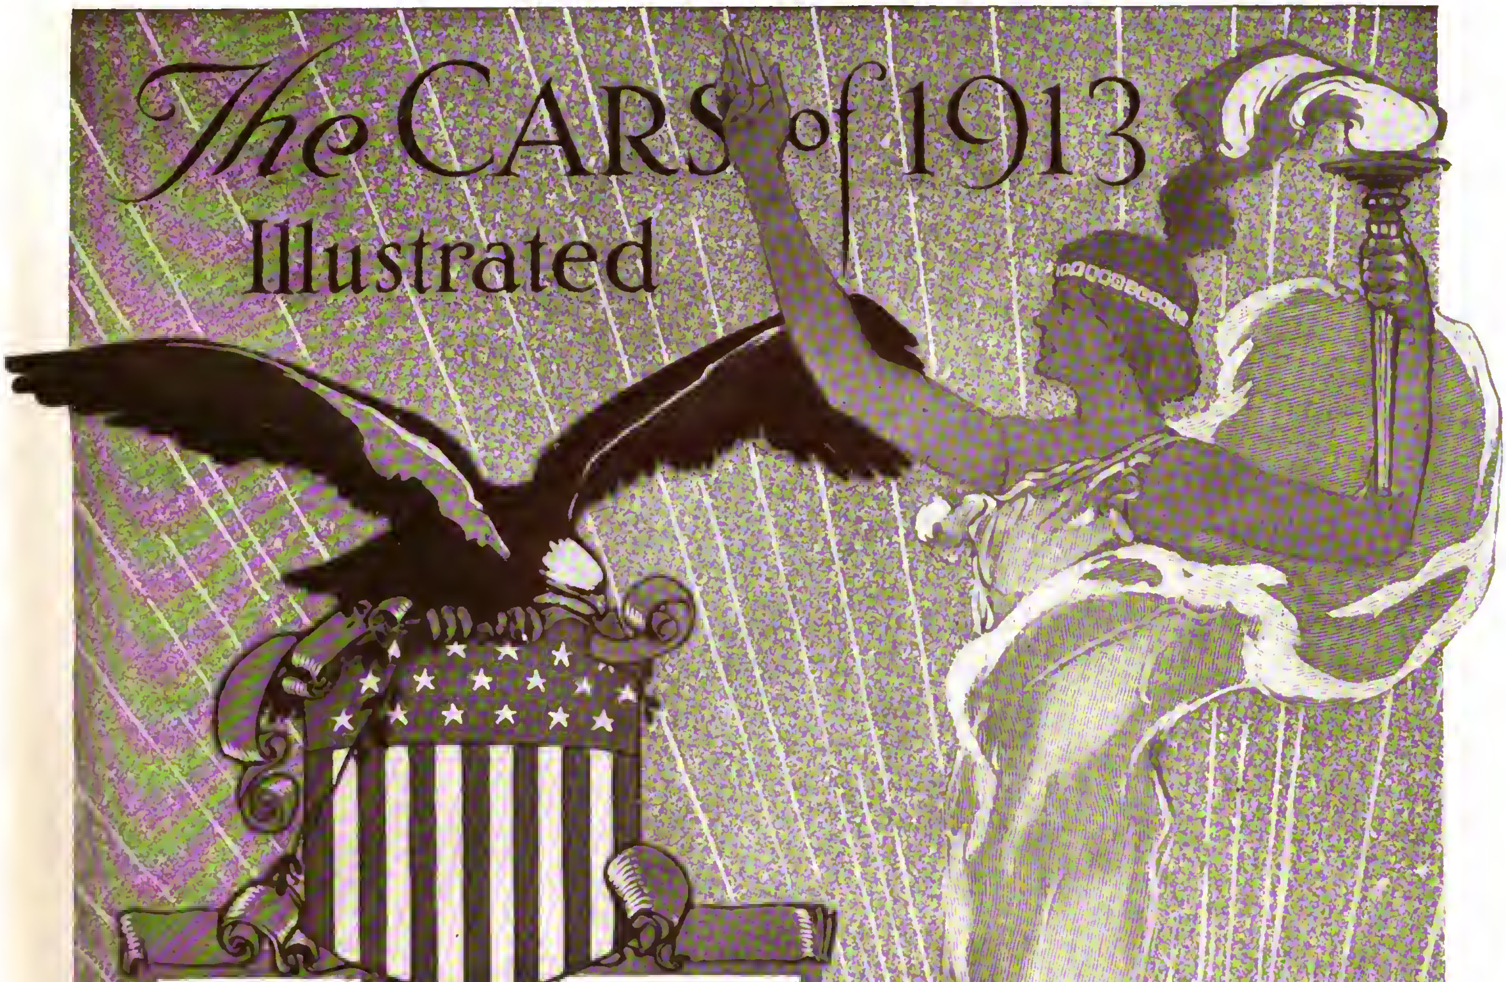
The CARS of 1913 Illustrated



CARS for 1913 are illustrative of a number of tendencies which have been growing for several years and have become sufficiently crystallized in this year's products to make them very noticeable. The first thing that strikes the casual observer of the cars as a whole is the increased beauty of line combined with utility of design which is exhibited. Long, flowing lines, easy curves, and smooth, clean-cut appearance are the rule this year instead of the exception among the open bodies, while in the closed cars two opposing tendencies which have been gaining for years have resulted in two distinct types of design, diametrically opposite in intent. One of these is the colonial style, which this year has been carried to a point almost of exaggeration, while the other is the stream-line effect, with its sweeping curves and subdued corners.

¶ Electric lighting and electric starting are the feature of the year in all classes of cars. Except in the very cheapest, electricity is relied upon to furnish not only the power for lighting the car but at the same time is utilized to take the place of the laborious hand cranking. This is only the latest evidence of the effort toward ease of operation and riding which is the aim of the engineers. The effort has resulted also in longer and more flexible springs, longer wheelbase and deeper upholstering.

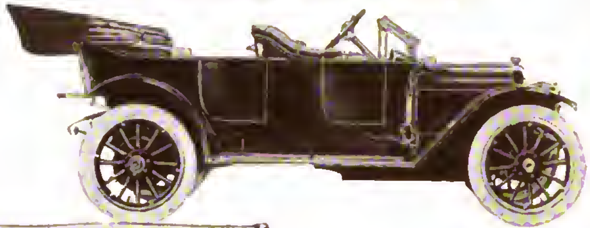
KISSELKAR 4-40 $2250

CASE N $2500



PULLMAN 4-44 $2250

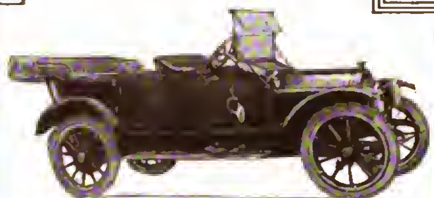
Five-Seated Touring Cars

THE losses in numbers are not evenly distributed. They are more pronounced in the high and low-priced classes and a distinct gain is shown in the division listing at $1,250-$2,000.

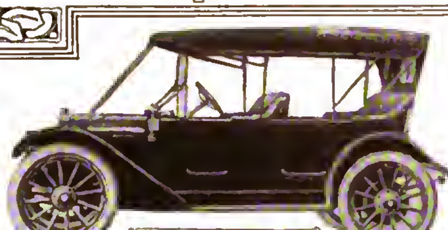
In the $1,000 division thirty-one models are made. This compares with fifty-two in 1912.

In the $1,500 class there has been a striking increase in touring car manufacture.

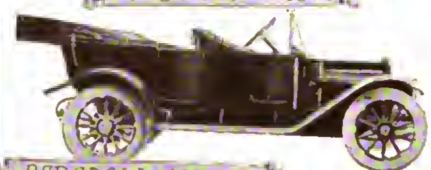
In 1913 there are 232 models, embracing 134 touring cars.



HUDSON 37 $1875



ARBENZ $1875



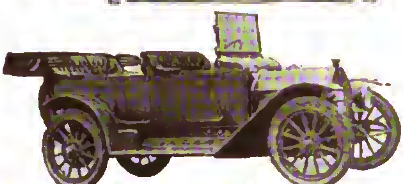
BERGDOLL 40 $2000

CRAWFORD 40 $2100

MOLINE M 40 $1950

WESTCOTT 30 $2475

PATHFINDER SERIES 13 $1875



LENOX 40 $2000

NYBERG 6-60 $2000

PALMER-SINGER SIX $2000

Staver 55. $2,250. 32.4 H.P., 120 W.B., 36 x 4 tires.
Pope 31. $2,250. 30.1 H.P., 118½ W.B., 36 x 4½.
Case N. $2,500. 27.25 H.P., 115 W.B., 34 x 4 tires.
Havers 55. $2,250. 38.4 H.P., 128 W.B., 36 x 4 tires.
Kisselkar 4-40. $2,250. 32.4 H.P., 121 W.B., 35 x 4½ and 35 x 4 tires.
Pullman 4-44. $2,250. 32.4 H.P., 122 W.B., 36 x 4 tires.
Hudson 37. $1,875. 27.25 H.P., 118 W.B., 36 x 4 tires.
Arbenz. $1,875. 27.3 H.P., 120 W.B., 36 x 4 tires.
Bergdoll 40, $2,000. 25.5 H.P., 121 W.B., 36 x 4 tires.
Crawford 40. $2,100. 32.4 H.P., 125 W.B., 36 x 4 tires.
Moline M-40. $1,950. 27.25 H.P., 124 W.B., 36 x 4 tires.
Westcott 30, $2,475. 38.4 H.P., 127 W.B., 37 x 4½ tires.
Pathfinder 13. $1,875. 27.25 H.P., 120 W.B., 36 x 4 tires.
Lenox 40, $2,000. 28.9 H.P., 118 W.B., 36 x 4 tires.
Nyberg 6-60, $2,000. 43.8 H.P., 128 W.B., 36 x 4 tires.
Palmer-Singer, $2,000. 38.4 H.P., 127 W.B., 36 x 4 tires.

Tourists of Medium Price

IN the $2,500 class there are 234 models and 143 touring cars against 288 models and 176 touring cars last year.

In the $4,000 class there are 322 models and 137 touring cars against 408 models and 173 touring cars in 1912.

Prices are steady to strong throughout the industry for the reason pointed out.

The tables show that the division listing between $1,250 and $2,000 has increased in number of manufacturers, number of models, and, of course, in volume of production.

Jackson Majestic, $1,850. 32.4 H.P., 124 W.B., 36 x 4 tires.
Schacht N. S., $1,775. 28.9 H.P., 120 W.B., 36 x 4 tires.
Rambler, $1,700. 32.4 H.P., 120 W.B., 36 x 4 tires.
Enger P. $1,750. 32.4 H.P., 120 W.B., 36 x 4 tires.
Marion 48A. $1,850. 27.25 H.P., 120 W.B., 36 x 4 tires.
Herreshoff 6. $1,700. 27.25 H.P., 124 W.B., 34 x 4 tires.
Richmond P., $1,750. 32.4 H.P., 120 W.B., 36 x 4 tires.
Stoddard-Dayton 30. $1,450. 25 H.P., 112 W.B., 34 x 4 tires.
Abbott-Detroit D. $1,750. 27.3 H.P., 116 W.B., 34 x 4 tires.
Cartercar 5A. $1.700. 27.25 H.P., 116 W.B., 36 x 4 tires.
Pratt 50. $1,850. 32.4 H.P., 120 W.B., 36 x 4 tires.
Imperial 34. $1,650. 32.4 H.P., 118 W.B., 36 x 4 tires.
Ames 40. $1,635. 27.3 H.P., 118 W.B., 36 x 4 tires.
Glide 36-42, $1,600. 27.25 H.P. 118 W.B., 34 x 4 tires.
Michigan 40R. $1,585. 28.9 H.P., 118 W.B., 35 x 4½ tires.
Great Western. $1.585. 28.9 H.P., 118 W.B., 26 x 4 tires

JACKSON MAJESTIC $1850

SCHACHT N S $1775

RAMBLER $1700

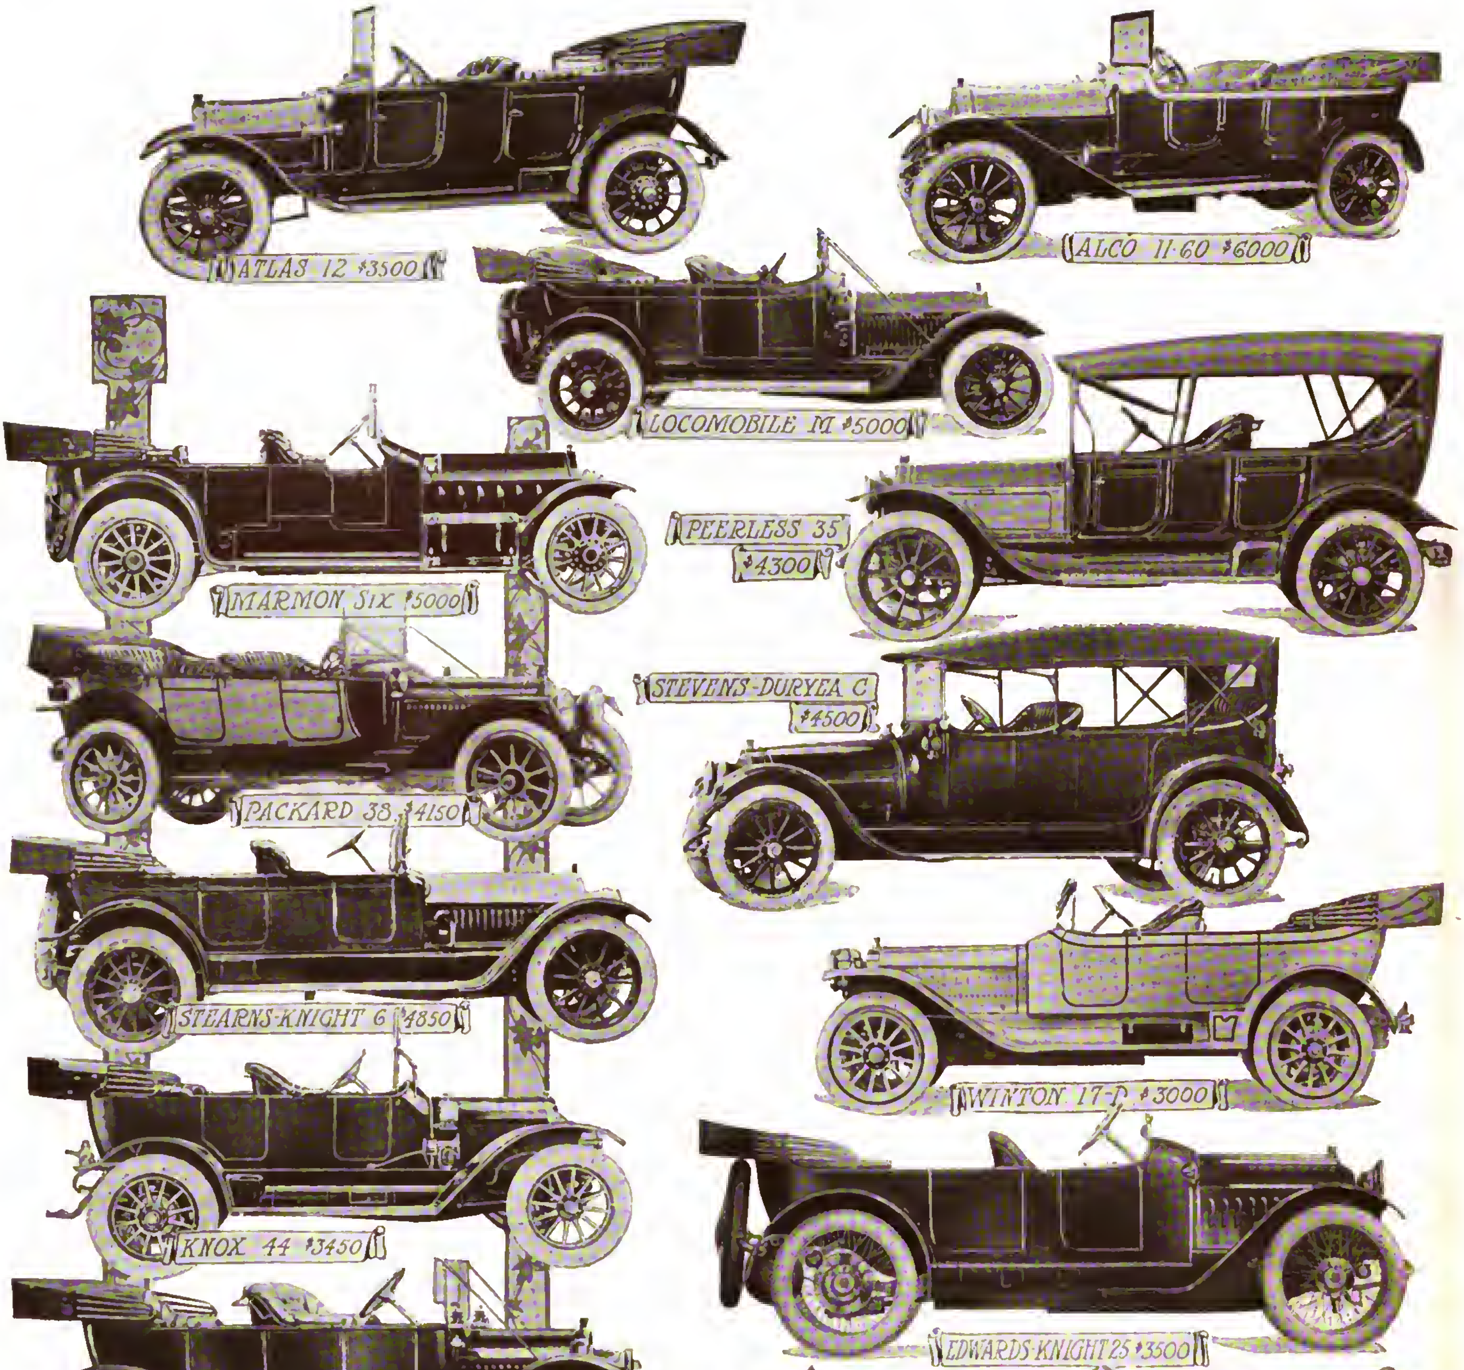
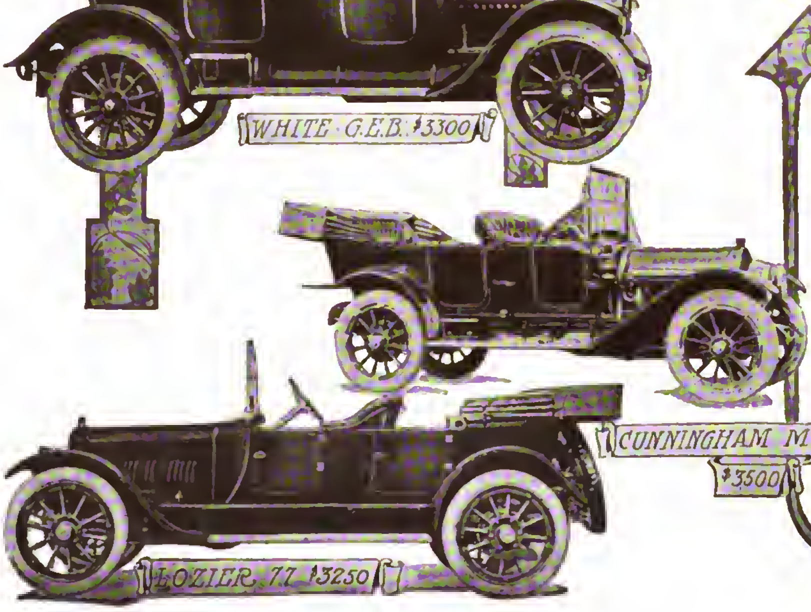
MICHIGAN 40 $1585

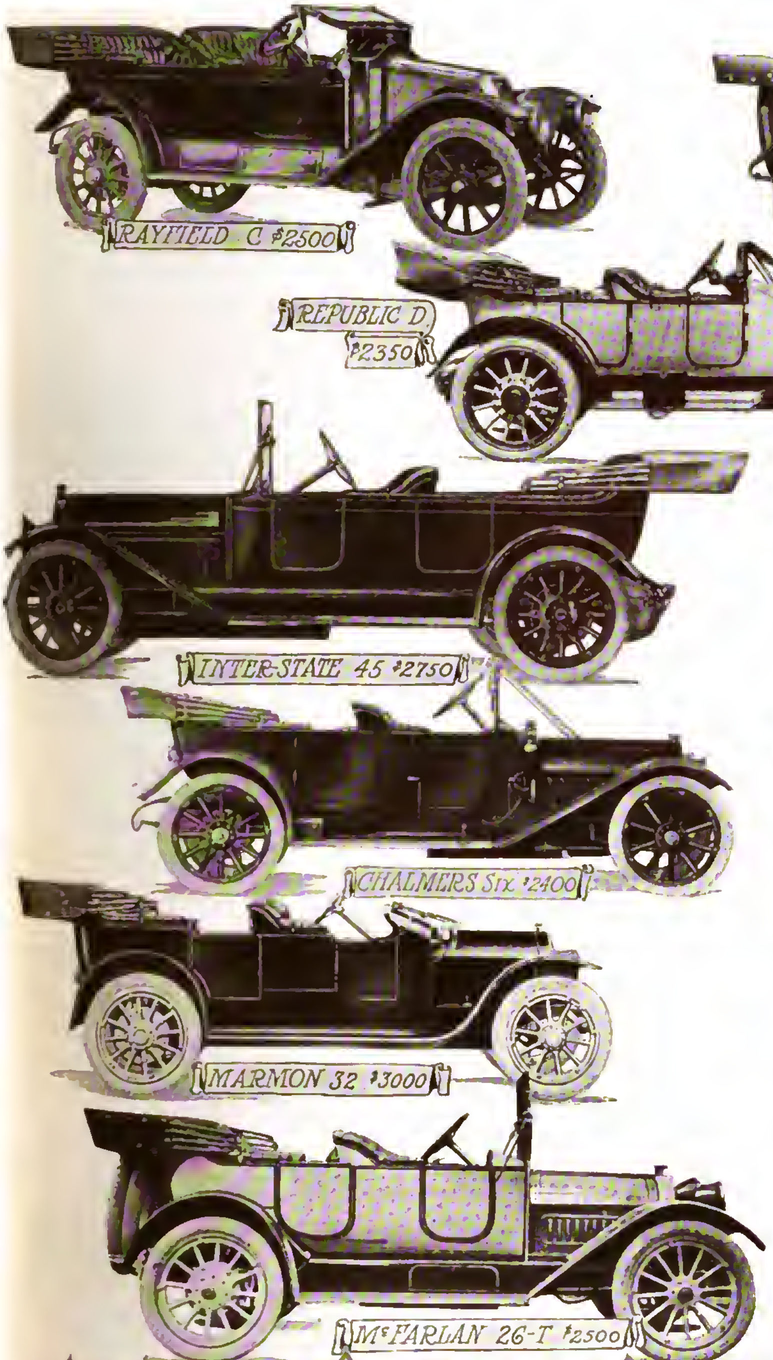
GREAT WESTERN $1585

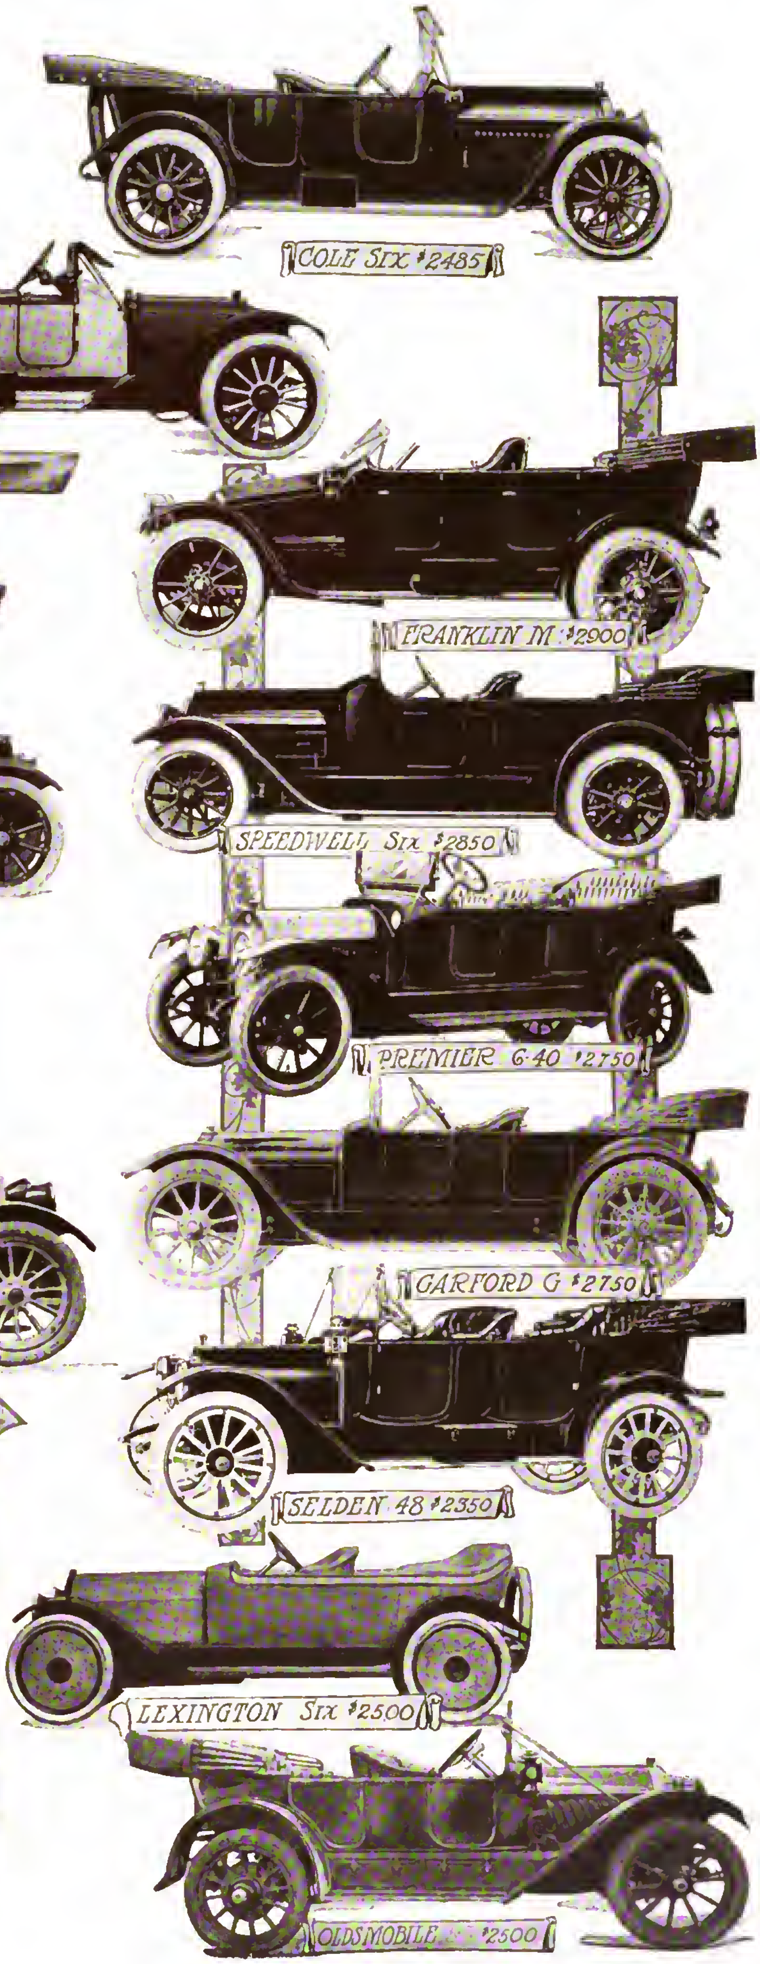




Five-Passenger Touring Cars at $3000 to $6000

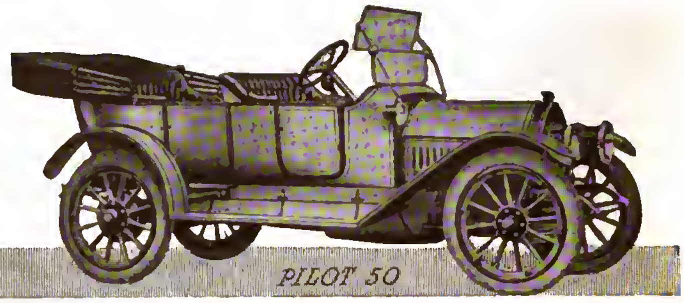
Atlas 12, $3,500. 32.4 H.P., 130 W.B., 37 by 5 tires.
Alco 11-60, $6,000. 54.1 H.P., 133½ W.B., 36 by 4½ and 37 x 5 tires.
Locomobile M, $5,000. 48.6 H.P., 136 W.B., 36 x 4½ and 37 x 5 tires.
Marmon Six, $5,000. 48.6 H.P., 145 W.B., 36 x 4½ and 37 x 5 tires.
Peerless 35, $4,300. 38.4 H.P., 125 W.B., 36 x 4½ tires.
Packard 38, $4,150. 38.4 H.P., 134 W.B., 36 x 4½ and 37 x 5 tires.
Stevens-Duryea C, $4,500. 46.1 H.P., 131 W.B., 37 x 4½ tires.
Stearns-Knight Six, $4,850. 43.8 H.P., 134 W.B., 37 x 5 tires.
Winton 17D, $3,000. 48-6 H.P., 130 W.B., 36 x 4½ tires.
Knox 44, $3,450. 40 H.P., 122 W.B., 36 x 4½ tires.
Edwards-Knight 25, $3,500. 25.6 H.P., 120 W.B., 36 x 4½ tires.
White GEB, $3,300. 28.9 H.P., 120 W.B., 36 x 4½ tires.
Cunningham M, $3,500. 36.1 H.P., 124 W.B., 36 x 4½ tires.
Lozier 77, $3,250. 31.6 H. P., 127½ W.B., 36 x 4½ tires.

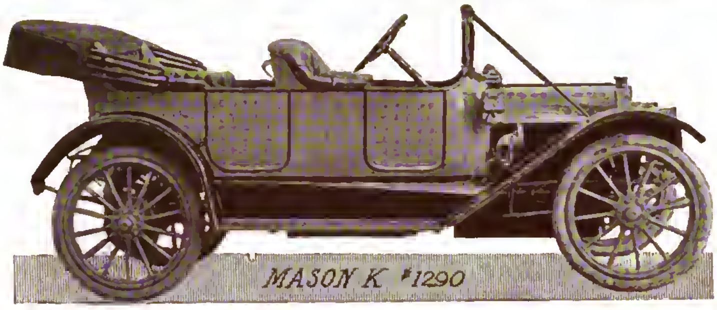


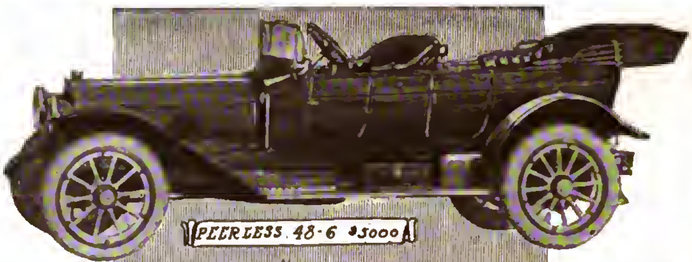


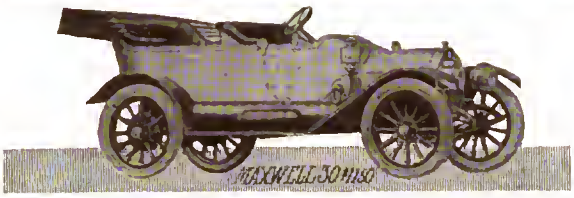
Open Cars for Five Passengers at $2400 to $3000

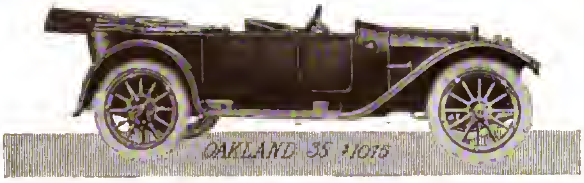
Rayfield C, $2,500. 29.4 H.P., 117 W.B., 34 x 4 tires.
Cole 60, $2,485. 40.9 H.P., 132 W.B., 37 x 4½ tires.
Republic D. $2,350. 28.9 H.P., 120 W.B., 36 x 4 tires.
Inter-State 45, $2,750. 38.4 H.P., 132 WB., 36 x 4½ tires.
Franklin M. $2,900. 31.6 H.P., 116 W.B., 34 x 4½ tires.
Chalmers 18, $2,400. 43.8 H.P., 130 W.B., 36 x 4½ tires.
Speedwell Six, G. $2,850. 40.9 H.P., 134 W.B., 36 x 4½ tires.
Marmon 32, $3,000. 32.4 H.P., 120 W.B., 35 x 4½ tires.
Premier 6-40, $2,750. 38.4 H.P., 132 W.B., 36 x 4½ tires.
McFarlan T, $2,500. 38.4 H.P., 124 W.B., 37 x 4½ tires.
Garford G, $2,750. 33.75 H.P., 128 W.B., 36 x 4½ tires.
Selden 48, $2,350. 36.1 H.P., 125 W.B., 36 x 4 tires.
Lexington 13-6, $2,500. 40.9 H.P., 129 W.B., 36 by 4½ tires.
Oldsmobile, $2,500.

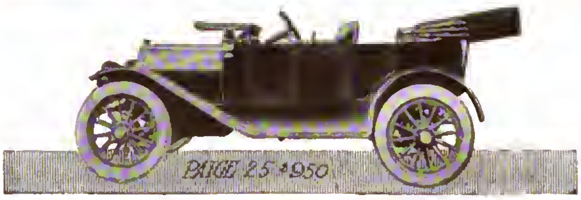


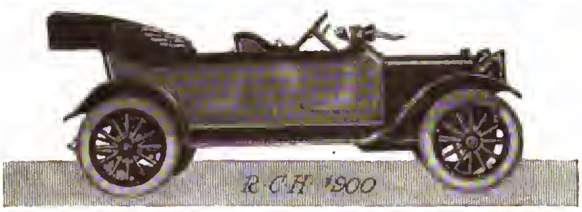


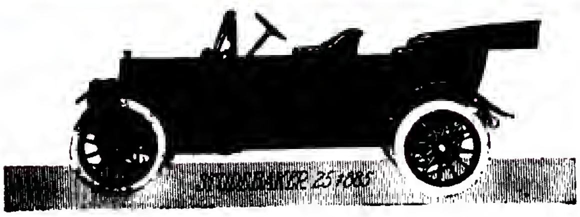








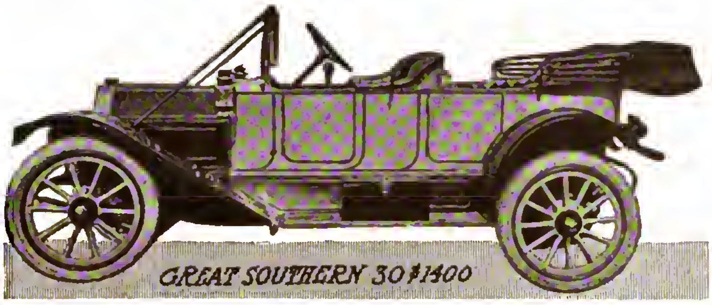


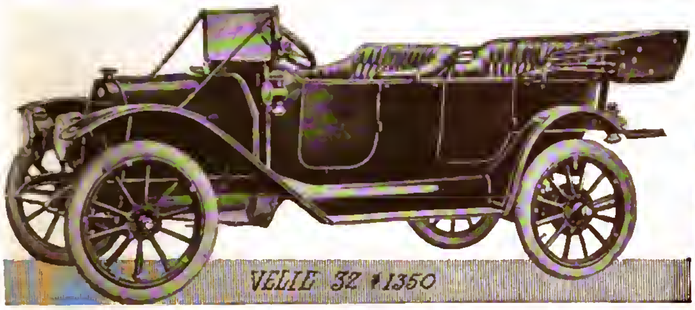


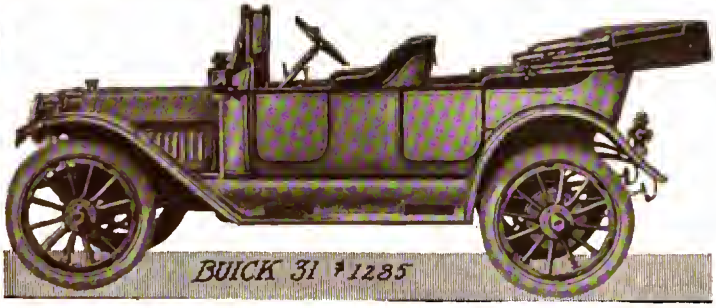
Six Seaters and Low Priced Touring Cars

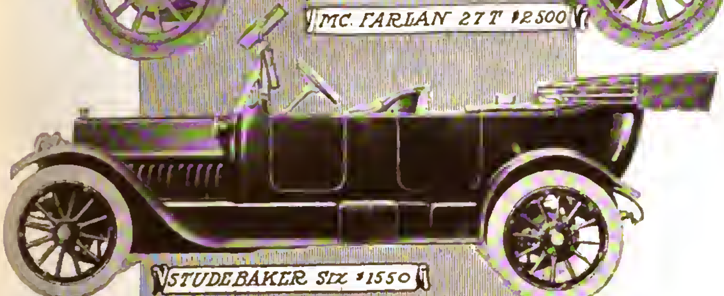
STRAIGHT, clean side lines, rounded lower rear sections of the body with more grace in the outward sweep of the rear seat, all of which are designed to prevent dust annoyance and to minimize wind-resistance, are the actual practical advances and betterments of the season.

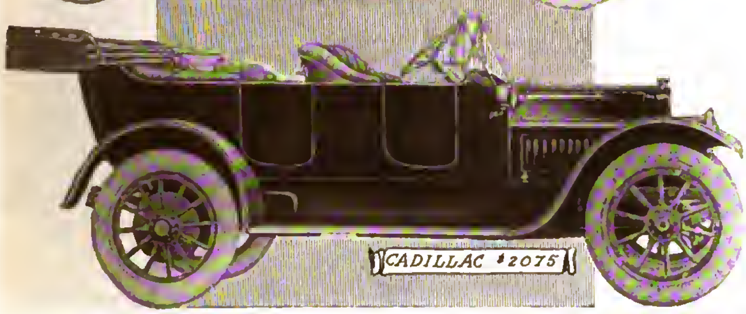
Henderson 47, six passengers, $1,485. 27.25 H.P., 116 W.B., 34 x 4 tires.
Pilot 50, $2.250. 32.4 H.P., 126 W.B., 36 x 4 tires.
Mason K, $1,290. 25.6 H.P., 116 W.B., 36 x 3½ tires.
Marathon Winner, $1,375. 28.9 H.P., 116 W.B., 34 x 4 tires.
Regal C, $1,250. 25.6 H.P., 116 W.B., 34 x 4 tires.
Peerless, six passengers, $5,000. 48.6 H.P., 137 W.B., 36 x 4½ and 37 x 5 tires.
Maxwell 50, $1,150. 25.6 H.P., 106 W.B., 32 x 3½ tires.
Oakland 35, $1,075. 19.6 H.P., 112 W.B., 32 x 3½ tires.
Paige 25, $950. 22.5 H.P., 110 W.B., 32 x 3½ tires.
R.C.H., $900. 16.9 H.P., 110 W.B., 32 x 3½ tires.
Studebaker 25, $885. 19.6 H.P., 101 W.B., 30 x 3½ tires.
Knox 46, six passengers, $4,350. 45.96 H.P., 134 W.B., 38 x 5 tires.
Schacht, N. S., six passengers, $2,500. 28.9 H.P., 120 W.B., 36 x 4 tires.

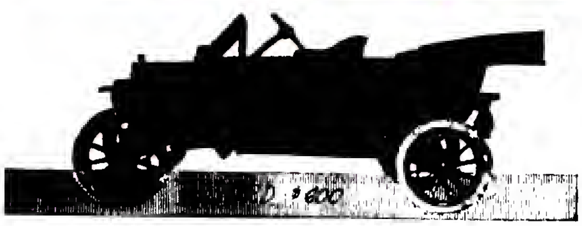








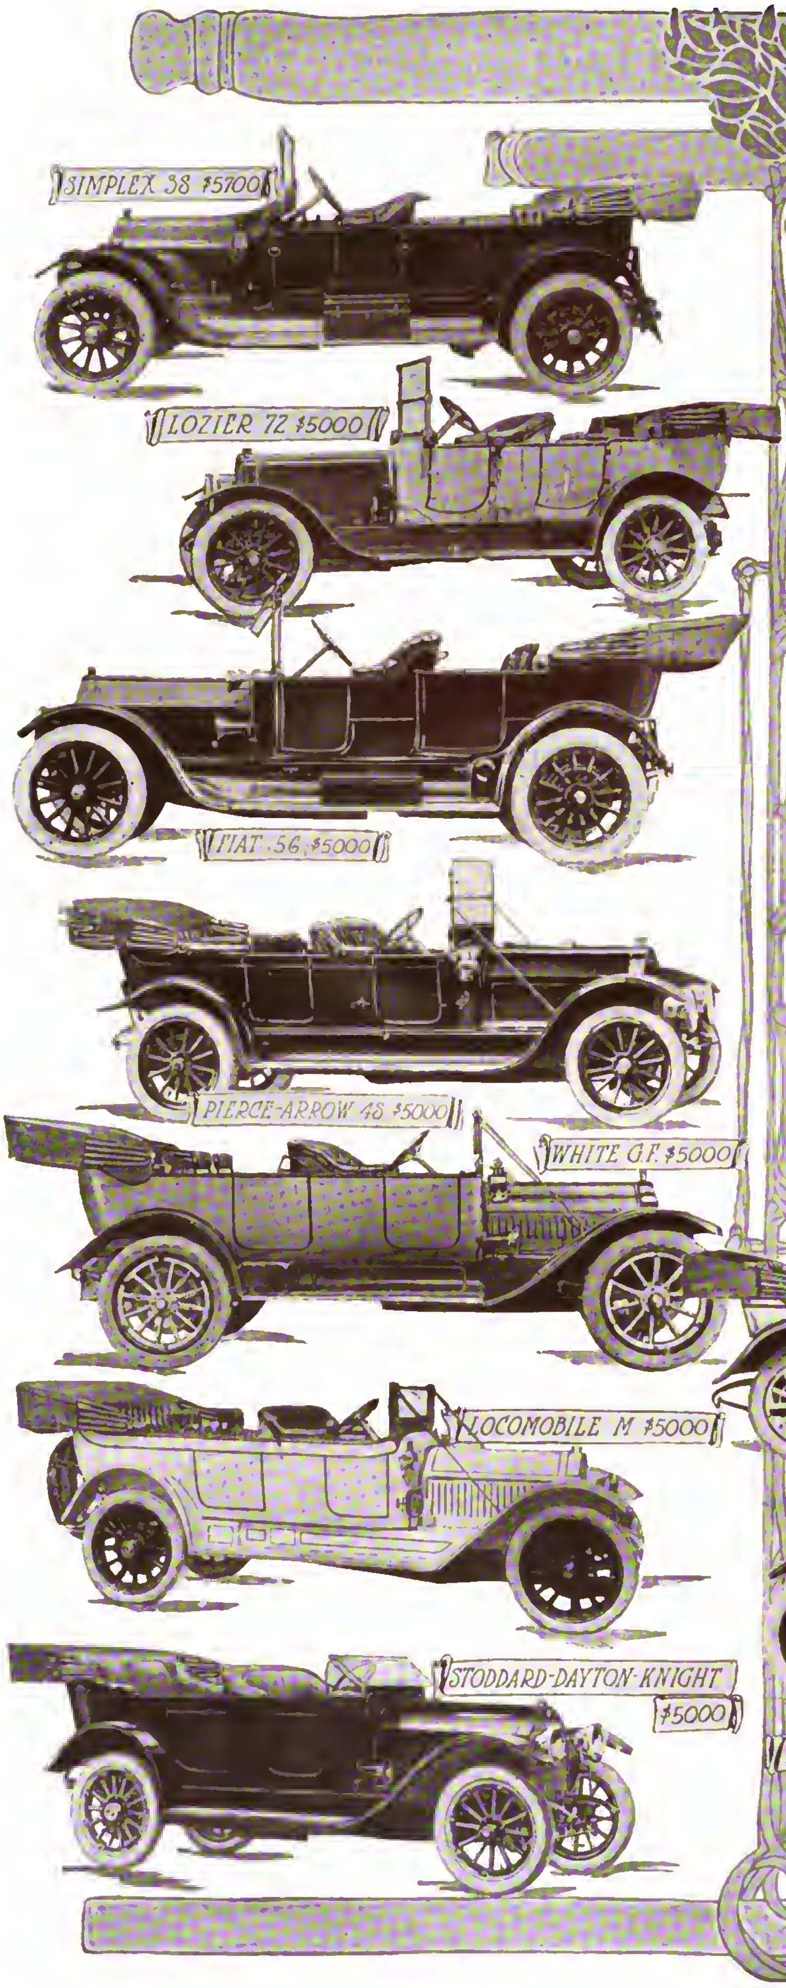


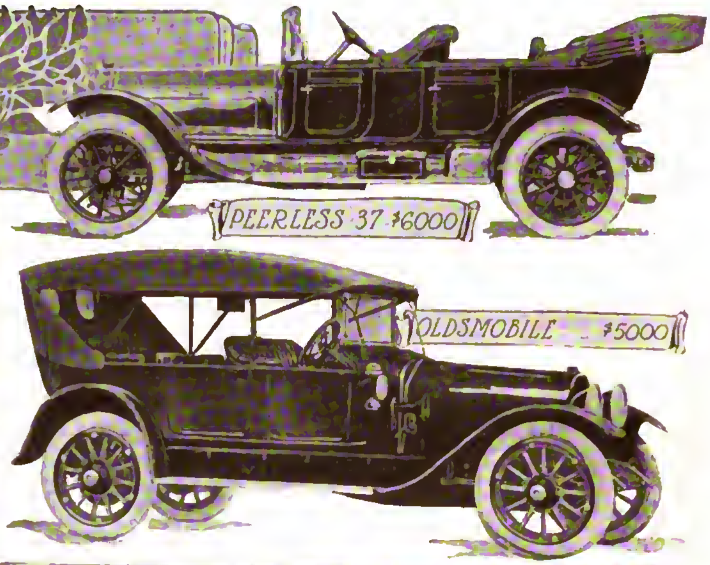


Five and Six Passenger Cars of Low Price

IMPROVEMENTS in touring bodies are generally developments of ideas thoroughly outlined in 1912. The most striking thing about the current touring car is its cleanness of outline. Throughout the offerings of 1913 the running boards are free from incumbrance.

Cutting B-40, $1,475. 25.6 H.P., 120 W.B., 36 x 4 tires.
Great Southern 30, $1,400. 25.6 H.P., 118 W.B., 34 x 4 tires.
Velie 32, $1,350. 22.5 H.P., 110 W.B., 34 x 3½ tires.
Buick 31, $1,285. 25.6 H.P., 108 W.B., 34 x 4 tires.
McFarland 27T, $2,500. 38.4 H.P., 124 W.B., 37 x 4½ tires.
Lambert 99, $1,250. 28.9 H.P., 117 W.B., 34 x 3½ tires.
Studebaker Six, six passengers, $2,550. 29.4 H.P., 121 W.B., 34 x 4 tires.
Reo 5, $1,095. 25.6 H.P., 112 W.B., 34 x 4 tires.
Cadillac, six passengers, $2,075. 32.4 H.P., 120 W.B., 36 x 4½ tires.
Overland, $985. 25.6 H.P., 110 W.B., 32 x 3½ tires.
Empire, $950. 19.6 H.P., 104 W.B., 32 x 3½ tires.
Detroiter, $900. 18.25 H.P., 104 W.B., 32 x 3½ tires.
Ford, $525. 22.5 H.P., 100 W.B., 30 x 3 tires.

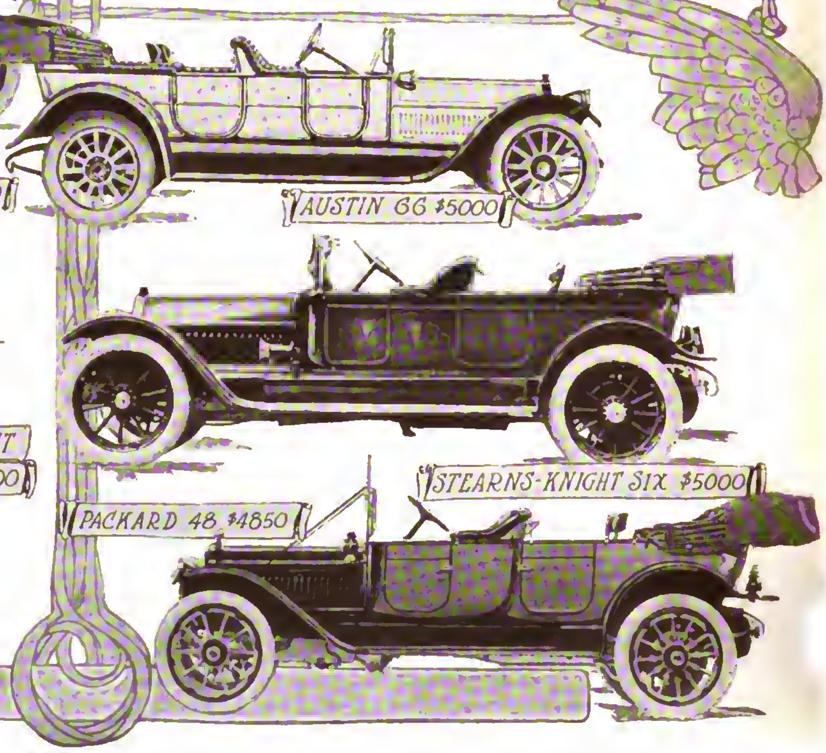


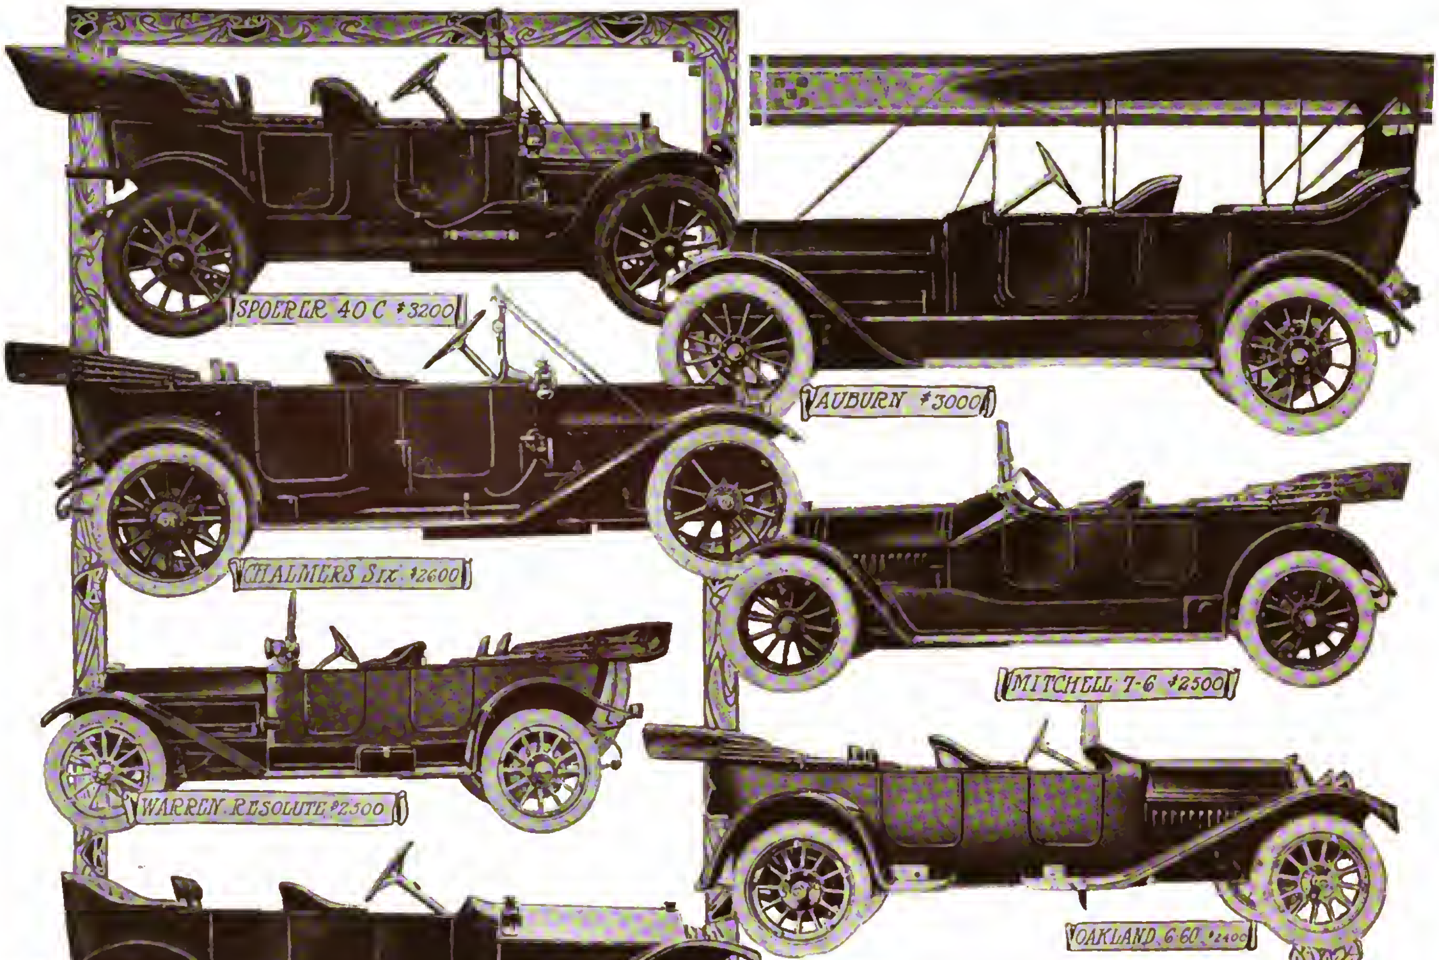


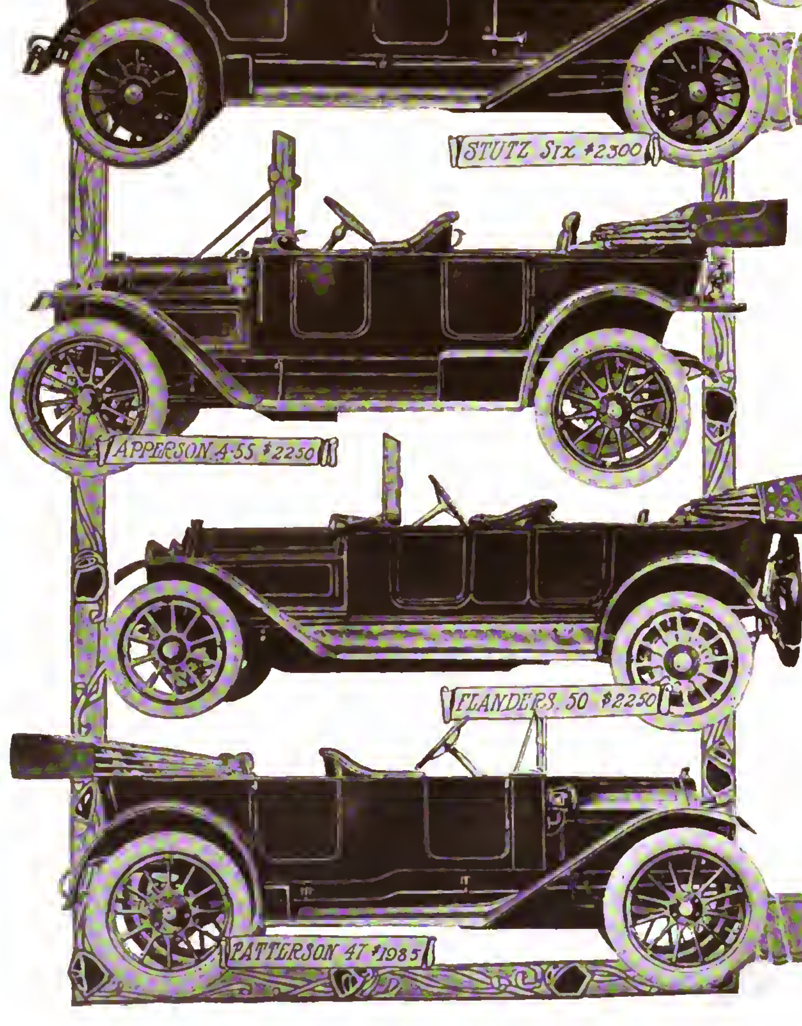
Seven-Passenger Touring Cars at $5000 to $6000

A VIEW of the seven-passenger touring car offerings of the year will explain some vital truths about the industry itself. There are ninety-one current models, against ninety last year. On the face of the tables it would seem as if only a slight increase had been scored for the seven-passenger car, while the truth is that the increase has been very large. In 1912 almost every manufacturer of large cars put out a foredoor model and a model without foredoors and the total appeared in the summaries. As an example, the Simplex put out five models of seven-passenger touring cars in 1912 and in 1913 the number listed is two.

Peerless, $6,000. 60 H.P., 140 W.B., 38 x 5½ tires.
Oldsmobile, $5,000. 40.9 H.P., 13 W.B., 36 x 4½ tires.
Simplex, $5,700. 38 H.P., 137 W.B., 35 x 5 tires.
Lozier 72, $5,000. 51.6 H.P., 131 W.B., 36 x 4½ and 27 x 5 tires.
Fiat 56, $5,000. 46.65 H.P., 135 W.B., 36 x 4½ and 37 x 5 tires.
Pierce-Arrow 48D, $5,000. 48.6 H.P., 134½ W.B., 37 x 5 tires.
White G. F., $5,000. 43.8 H.P., 132 W.B., 37 x 5 tires.
Austin 66, $5,000.
Locomobile M, $5,000. 48.6 H.P., 136 W.B., 36 x 4½ and 37 x 5 tires.
Stoddard-Dayton-Knight, $5,000. 48.6 H.P., 133 W.B., 30 x 5 tires.
Stearns-Knight Six, $5,000. 43.8 H.P., 140 W.B., 37 x 5 tires.
Packard 48, $4,850. 48.6 H.P., 139 W.B., 30 x 4½ and 37 x 5 tires.



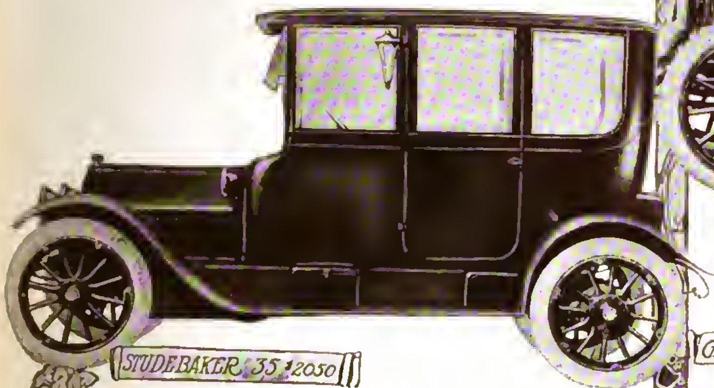


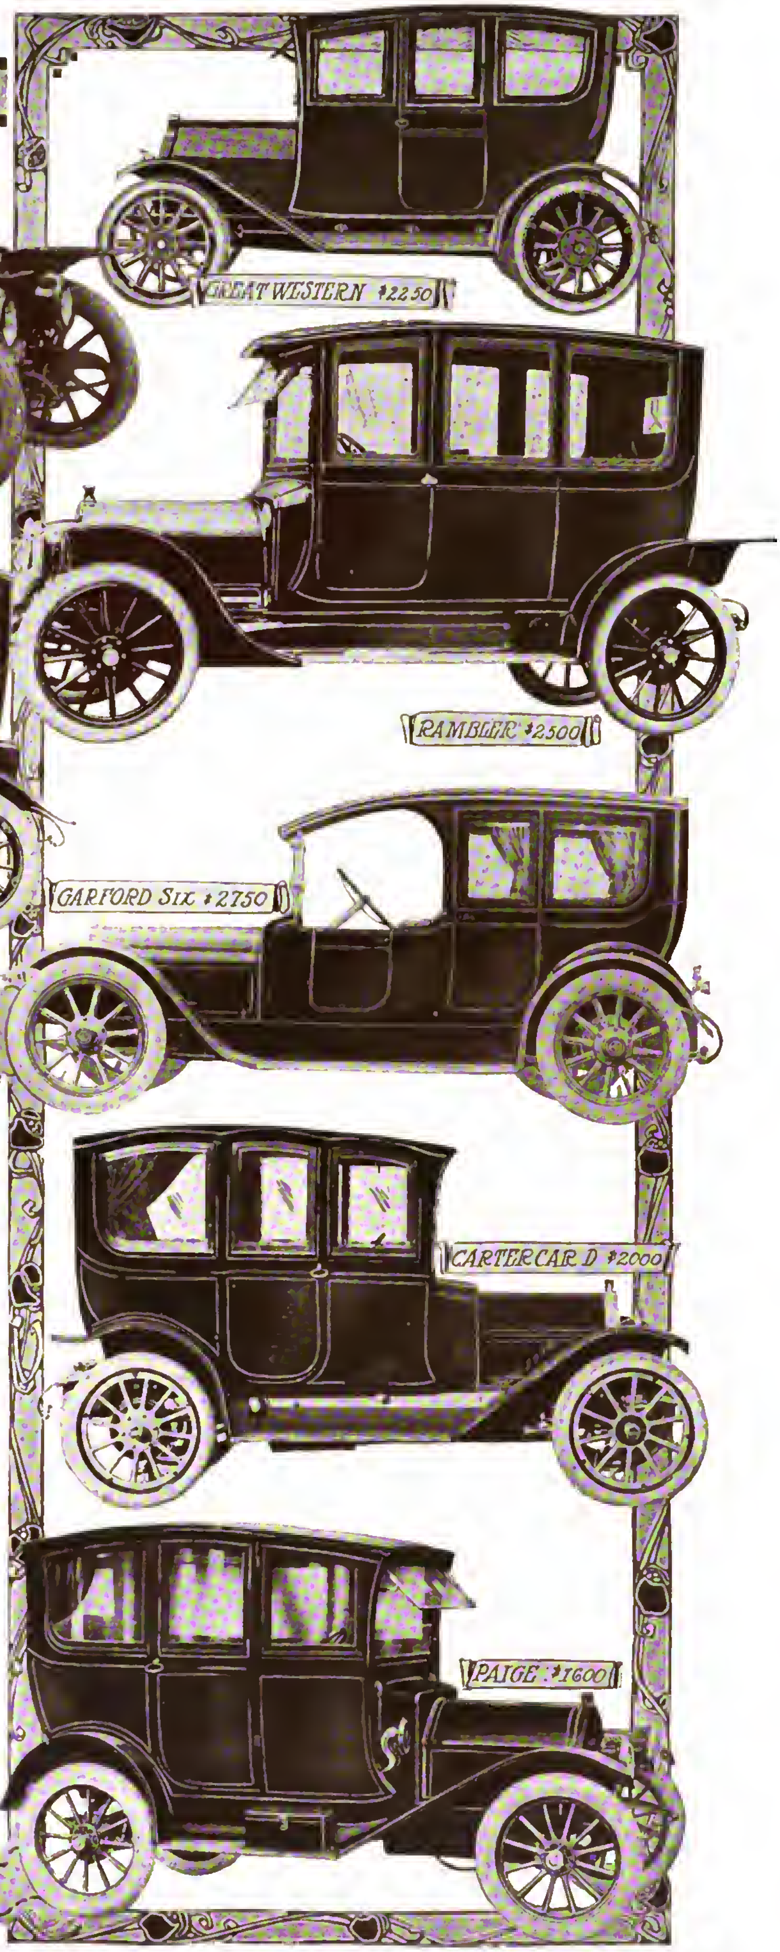


Low Priced Touring Cars

EVEN with full consideration of the multiplicity of models put out last year on account of duplications due to the introduction of foredoors, a view of the $2,500 class shows the immense advance that has been made. There are thirty-one models in the 1913 collection against twenty-five in 1912. The accessions to the class number the A. E. C., Alpena, Auburn, Burg, Carroll, Chevrolet, Croxton, Duquesne, Garford, Great Western, Holly, Hudson, Keeton, Moyer, Norwalk, Nyberg, Pilot, Pope-Hartford, Premier, Schacht, Studebaker, Touraine and Warren. Several of these companies are just entering business.

Spoerer, 40C, $3,200. 38 H.P., 120 W.B., 37 x 4½ tires.
Auburn 6-50, $3,000. 40.9 H.P., 135 W.B., 37 x 4½ tires.
Chalmers Six, $2,600. 43.8 H.P., 130 W.B., 36 x 4½ tires.
Mitchell 7-6, $2,500. 43.8 H.P., 144 W.B., 36 x 4½ tires.
Warren Resolute, five passengers, $2,500. 38.4 H.P., 130 W.B., 36 x 4½ tires.
Oakland 6-60, five passengers, $2,400. 40.9 H.P., 130 W.B., 34 x 4½ tires.
Stutz 6, six passengers, $2,300. 43.8 H.P., 130 W.B., 34 x 4½ tires.
Apperson 4-55, seven passengers, $2,250. 36.1 H.P., 122 W.B., 36 x 4½ tires.
Flanders 50, seven passengers, $2,250. 38.4 H.P., 130 W.B., 36 x 4½ tires.
Patterson 47, $1,985. 32.4 H.P., 122 W.B., 36 x 4 tires.

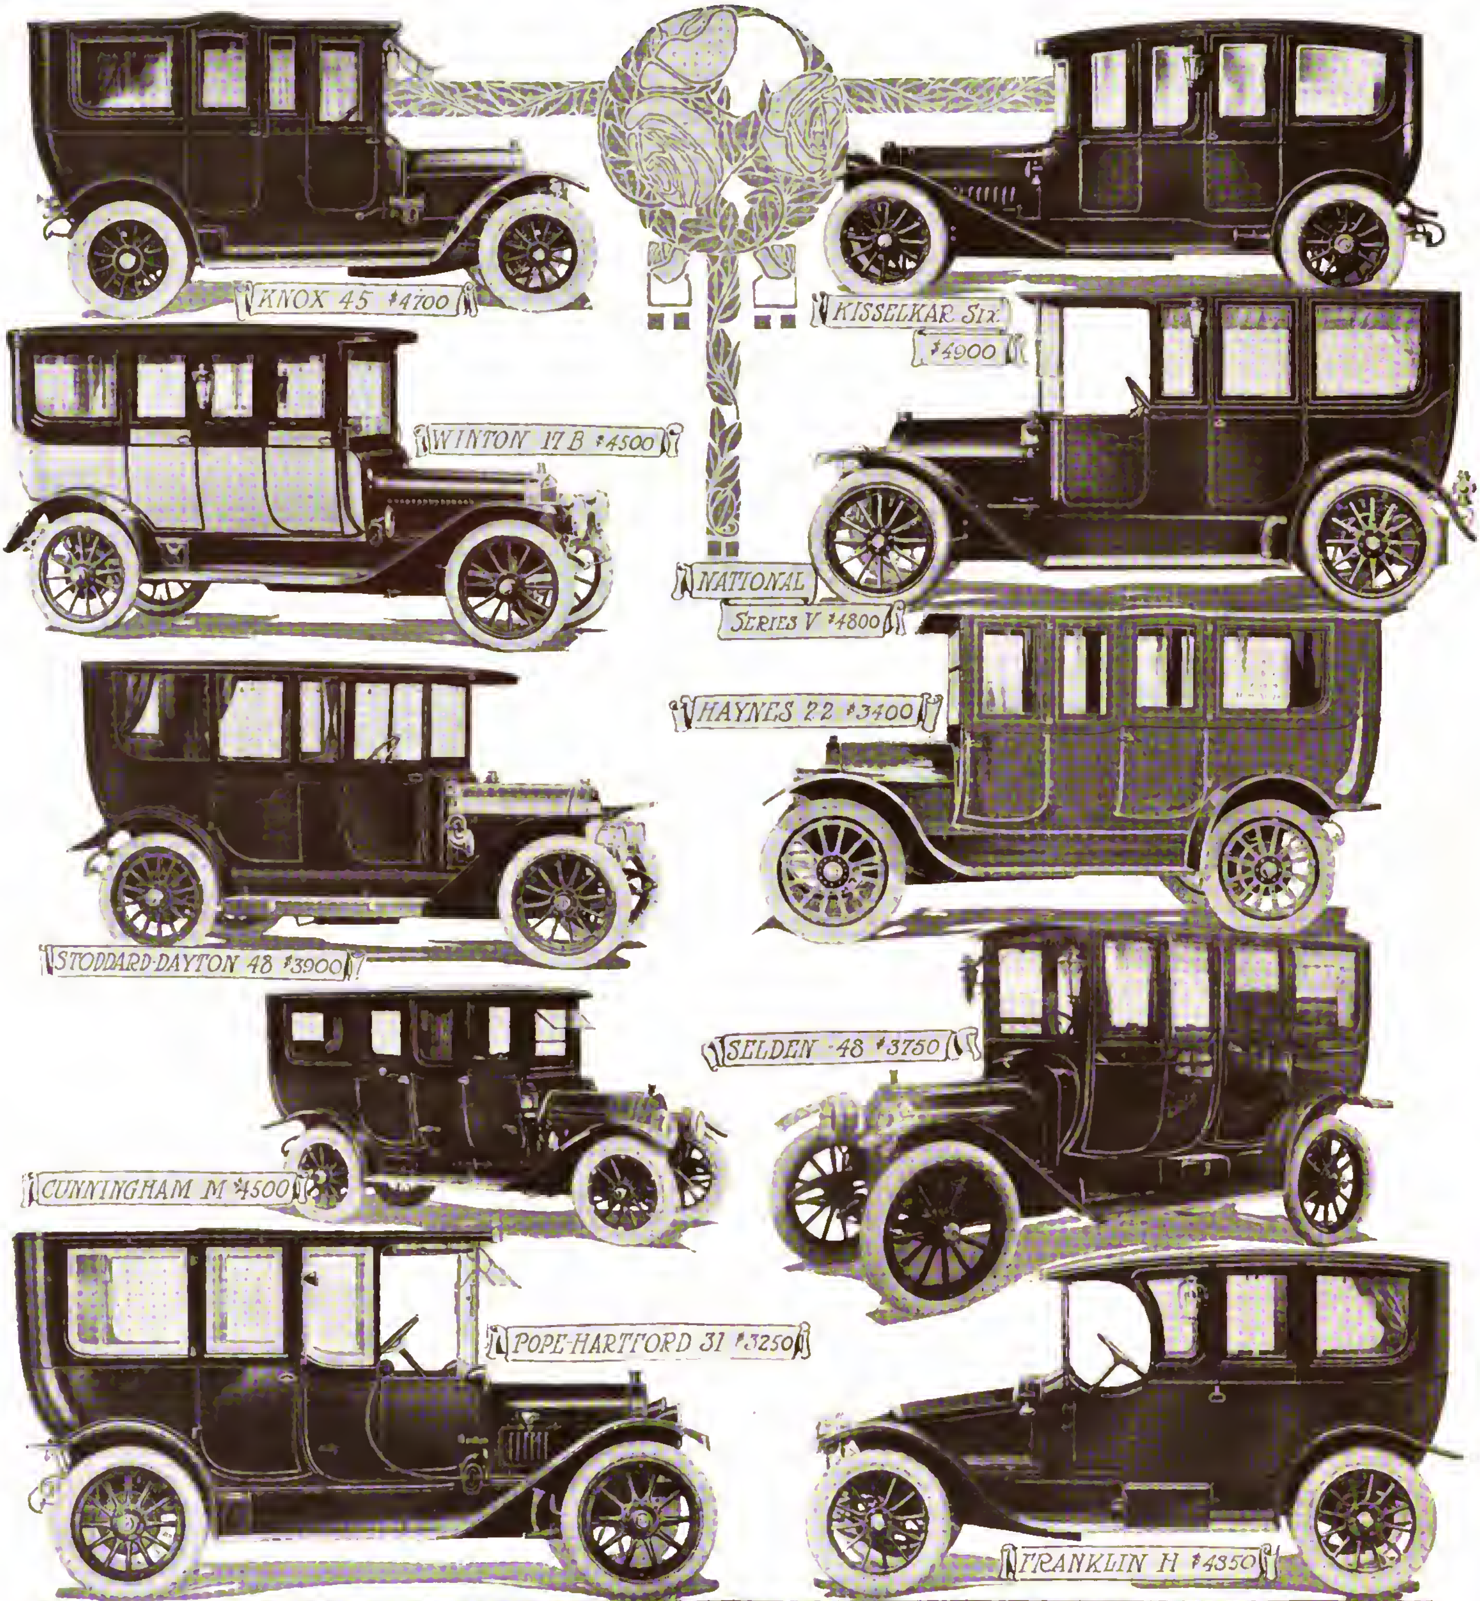




New Compartment Bodies

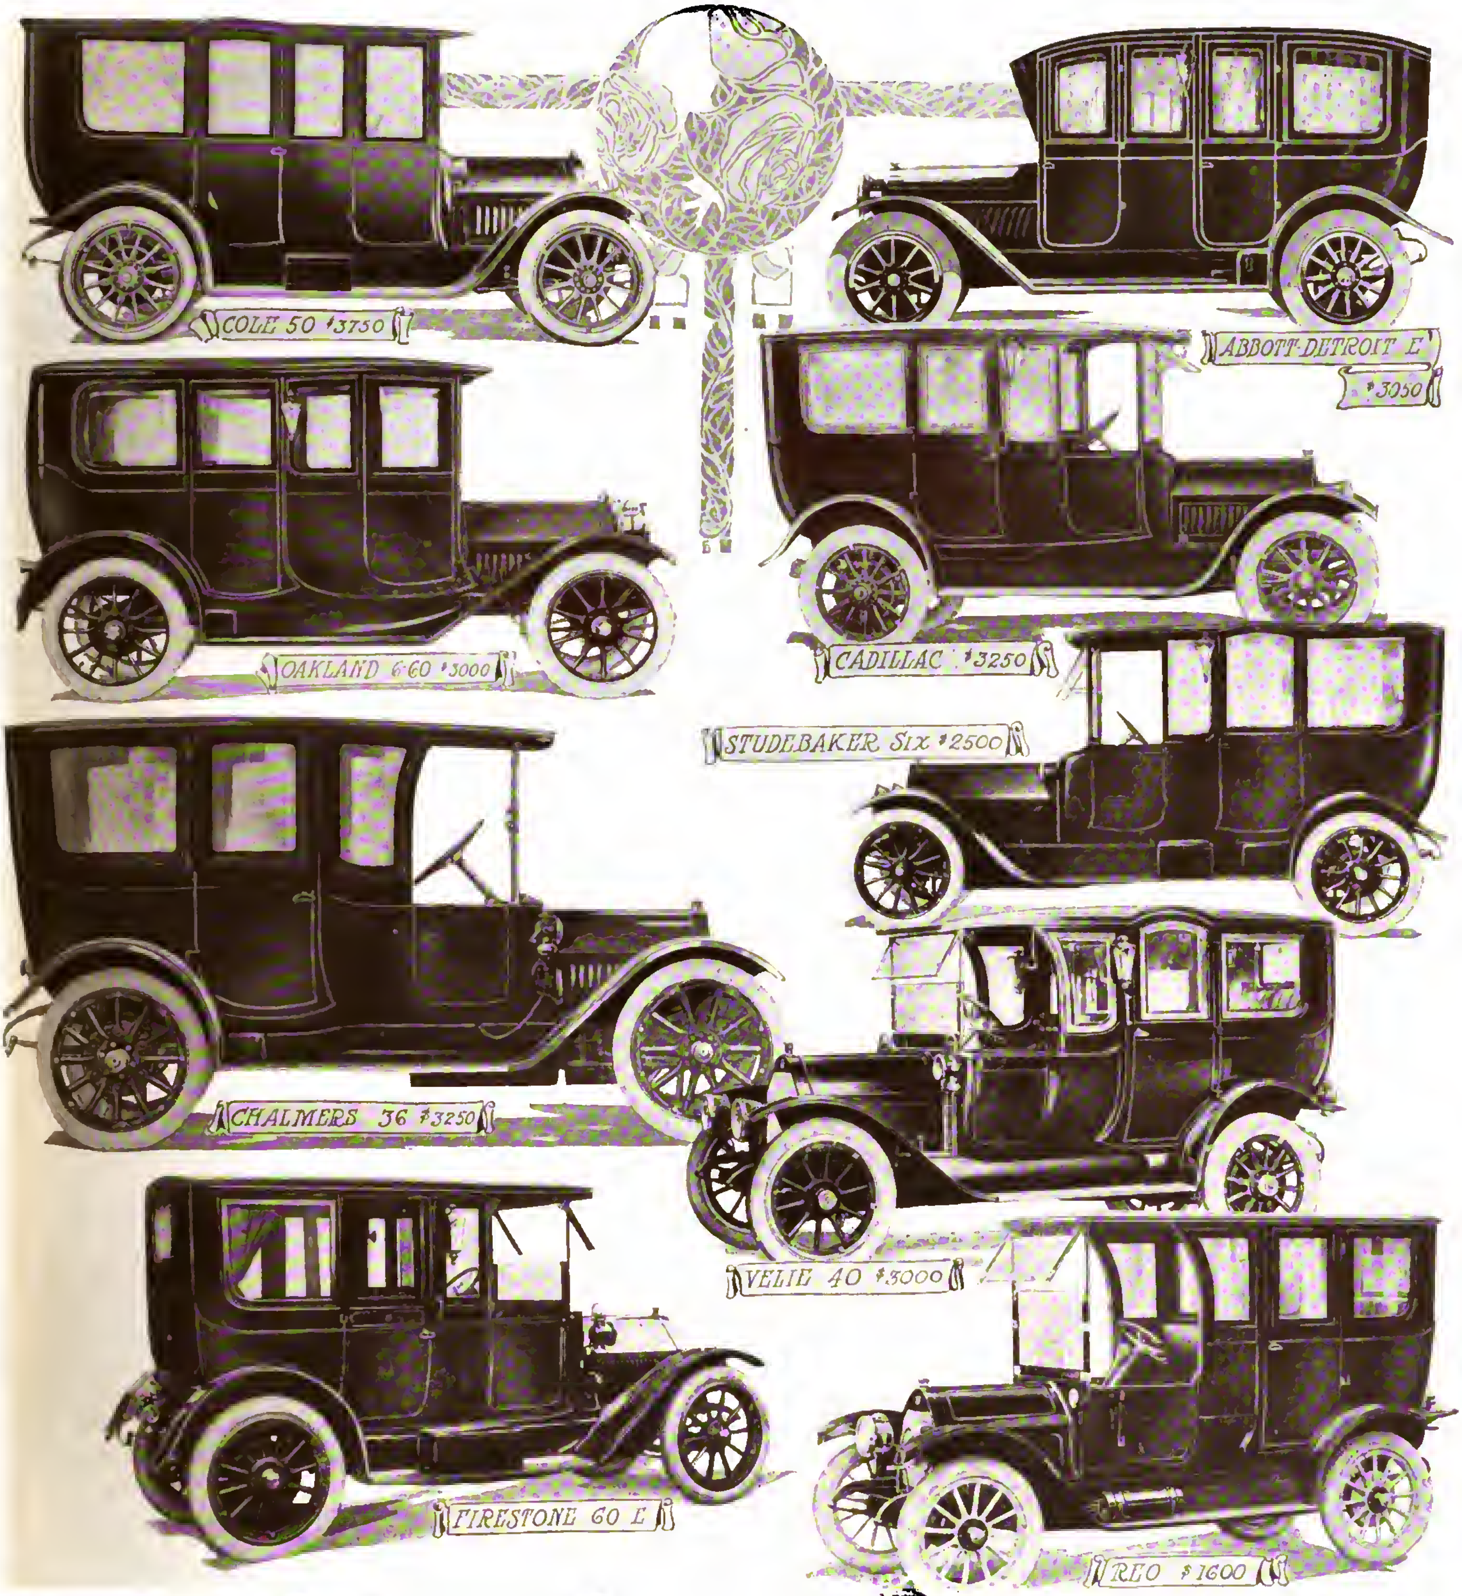
SINGLE-compartment cars constitute one of the main variations from the formal types of inclosed bodies. These cars are so arranged that the driver is not separated from the other passengers. On some there is but a single door at one side, whereas others have a door on each side in staggered relation to each other. The driver's seat is generally an arm-chair type, and that of the passenger at his side usually a revolving or folding-chair type. The cars differ little in other respects from the established types. The idea involved in this style of body is to reduce the distinction between driver and passengers to such an extent that the owner of the car may figure as driver if it should be desirable for him to do so or the chauffeur may be used as in other inclosed types by simply raising a glass partition. In the high-priced class the equipment is fuller than ever before. Electric cigar lighters, special fittings for flower vases and other refinements have become very frequent.

S.G.V., seven-passenger landaulet, $4,000, 25.6 H.P., 118 W.B., 35 x 4½ tires.
Great Western, Sedan, four passengers, $2,250, 28.9 H.P., 118 W.B., 36 x 4 tires.
Studebaker 35, five-passenger sedan, $2,050, 27.25 H.P., 115½ W.B., 34 x 4 tires.
Rambler, five-passenger limousine, $2,500, 32.4 H.P., 120 W.B., 37 x 4½ tires.
Garford G, four-passenger compartment, $2,750, 33.75 H.P., 128 W.B., 36 x 4½ tires.
Cartercar D, five-passenger sedan, $2,000, 27.25 H.P., 116 W.B., 36 x 4 tires.
Paige, five-passenger compartment, $1,600, 25.6 H.P., 116 W.B., 34 x 4 tires.



Enclosed Cars Seating Five or More Passengers

Knox 45, seven passenger, price $4,700. 40 H.P., 126 W.B., 37 x 5 tires.
Kisselkar 60, seven passenger, $4,900. 48.6 H.P., 140 W.B., 37 x 5 tires.
Winton 17D, seven passenger, $4,500. 48.6 H.P., 130 W.B., 36 x 4½ tires.
National V, seven passenger, $4,800. 38 H.P., 128 W.B., 36 x 5 tires.
Stoddard-Dayton 48, seven passenger, $3,900. 36.1 H.P., 122½ W.B., 36 x 4½ tires.
Haynes 22, seven passenger, $3,400. 32.4 H.P., 120 W.B., 36 x 4½ tires.
Cunningham M, seven passenger, $4,500. 36.1 H.P., 124 W.B., 36 x 4½ tires.
Selden 48, seven passenger, $3,750. 36.1 H.P., 125 W.B., 37 x 4½ tires.
Pope-Hartford 31, five passenger, $3,250. 30.25 H.P., 118½ W.B., 36 x 4½ tires.
Franklin H, seven passenger, $4,850. 38.4 H.P., 126 W.B., 37 x 5 tires.



Lower Priced Limousines, Landaulets and Berlines

Cole 50, seven passenger, $3,750. 40.9 H.P., 132 W.B., 37 x 4¼ tires.

Abbott-Detroit E, seven passenger, $3050. 32.4 H.P., 121 W.B., 36 by 4¼ tires.

Oakland 6-60, seven passenger, $3,000. 40.9 H.P., 130 W.B., 34 x 4¼ tires.

Cadillac, seven passenger, $3,250. 32.4 H.P., 120 W.B., 36 x 4½ tires

Studebaker, seven passenger, $2,500. 20.4 H.P., 121 W.B., 34 x 4 tires.

Chalmers 17, seven passenger, $3,250. 28.9 H.P., 118 W.B., 37 x 4½ tires.

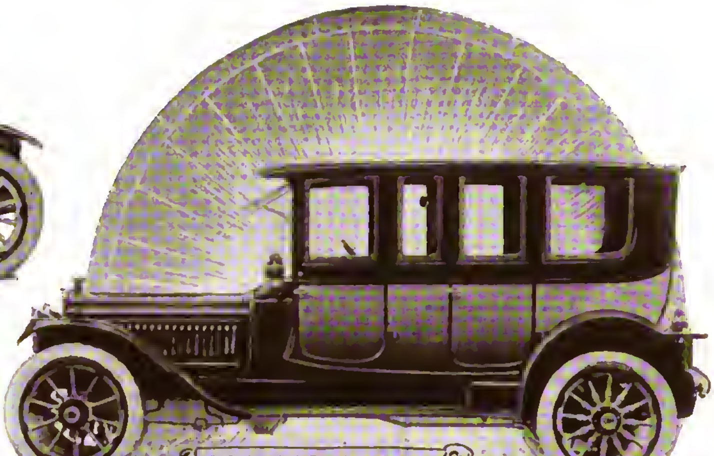
Velie 40, five passenger, $3,000. 32.4 H.P., 118 W.B., 36 x 4 tires.

Firestone-Columbus, 60-E, seven passenger, 32.4 H.P., 122 W.B., 32 x 4 and 36 x 4 tires.

Reo 5, seven passenger, $1,600. 25.6 H. P., 112 W.B., 34 x 4 tires.

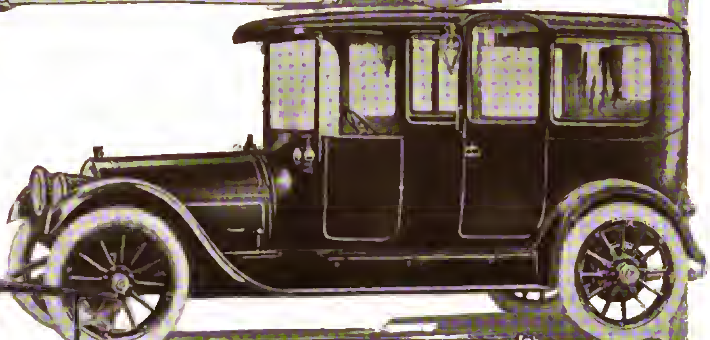
SIMPLEX 38 $6500

LOCOMOBILE R $5350

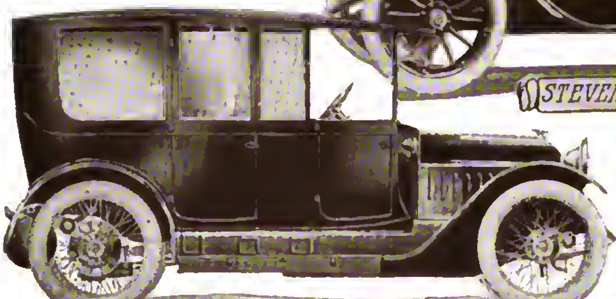


PACKARD 48 $5200

STEARNS-KNIGHT 4 $5000



STEVENS-DURYEA C $5500



EDWARDS-KNIGHT 25 $4600

WHITE SIX G.F. $6300

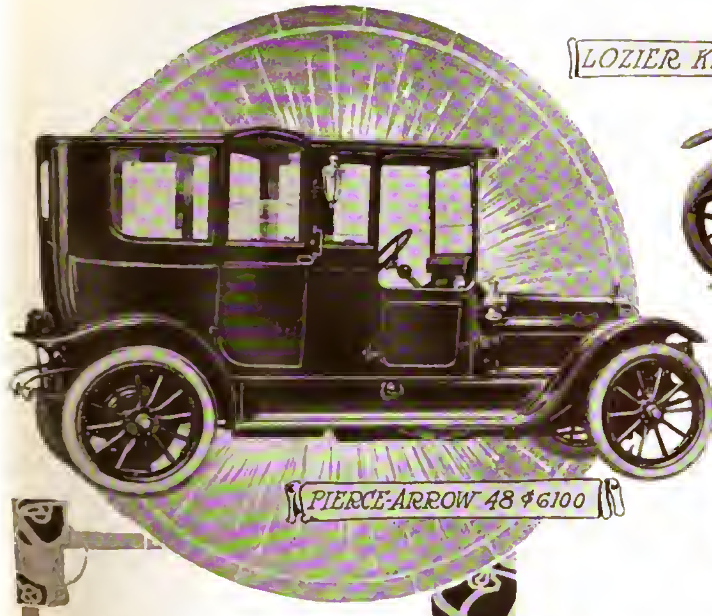
Enclosed Cars of Larger Capacity

THE entire field of the closed car has been subjected to the same changes and improvements that have been noted with regard to other current automobiles.

Much has been said in favor of the curved roof, bending down in front and having a tendency to limit the perpendicular range of vision. This idea has been adopted in modified form and has been incorporated pretty generally throughout the industry in conjunction with larger side windows. Extreme types embodying the idea of colonial coach-building are to be seen, but the straight-topped car, with enough flare and curved outlines in the lower portion of the body to get away from the freight car appearance of earlier years, is still a popular standard type.

There is a marked tendency to shorten the projecting roof over the driver's seat in broughams and towncars, but in the limousine and landaulet models the projection is carried out beyond the windshield. Electric lamps built into the bodies the surface being flush with the lines of the car are widely used.

Simplex 38, seven passengers, $6,500. 38 H.P., 137 W.B., 35 x 5 tires.
Packard 48, seven passengers, $5,200. 48.6 H.P., 139 W.B., 36 x 4½ and 37 x 5 tires.
Locomobile R, seven passengers, $5,350. 43.8 H.P., 128 W.B., 36 x 4½ tires.
Stearns-Knight 4, five passengers, $5,000. 28.9 H.P., 121 W.B., 36 x 4½ tires.
Stevens-Duryea C, seven passengers, $5,500. 46.1 H.P., 131 W.B., 37 x 4½ and 37 x 5 tires.
Edwards-Knight 25, seven passengers, $4,600. 25.6 H.P., 120 W.B., 36 x 4½ tires.
White GF, seven passengers, $6,300. 43.8 H.P., 132 W.B., 37 x 5 tires.



Limousines and Landaulets

IN the closed-car types, having passenger capacity of from five to ten persons many models have been eliminated in the class selling for over $3,000. Statistics show that the market affords a choice of only 154 models, while last year there were thirty more. Four more models have been added to the $2,000-$3,000 class, making a total of fourteen, and the net loss in the high-priced line is thirty-five. The addition of the single offering in the $1,250-$2,000 class makes the total count 154 for 1913 against 184 for 1912.

The sedan, an enlargement of the coupé idea but seating five or six passengers, is the distinctive feature of the year. Limousines, landaulets, berlines, broughams and towncars are included in the classification generally and are continued in somewhat reduced numbers by all the manufacturers in active manufacturing who made them last year.

Passenger compartments are larger, lower and better balanced than heretofore. The softening of angles is a well-nigh universal tendency. One concern puts out two limousine models with a carrying capacity of ten persons each.

Pierce-Arrow 48D, seven passengers, $6,100. 48.6 H.P., 134½ W.B., 37 x 5 tires.
Lozier Knickerbocker, seven passengers, $6,500. 51.6 H.P., 131 W.B., 36 x 4½ and 37 x 5 tires.
Stevens-Duryea C, seven passengers, $5,750. 46.1 H.P., 138 W.B., 37 x 4½ and 37 x 5 tires.
Simplex 137, seven passengers, $6,500. 38 H.P., 137 W.B., 35 x 5 tires.
Packard 38, seven passengers, $5,400. 38.4 H.P., 134 W.B., 36 x 4½ and 37 x 5 tires.
Columbia Knight 88, seven passengers, $5,800. 38 H.P., 129 W.B., 36 x 4½ tires.
Peerless 36, seven passenger, $6,200. 48.6 H.P., 137 W.B., 36 x 4½ and 37 x 5 tires.

ARBENZ H $1825

Runabouts Listed at $1500 to $2000

As indicated so strongly last year, the tendency toward storing the spare tires at the rear, either upon the flat or sloping deck or in holders at the extreme end, has been developed and adopted by almost every maker.

In appearance the 1913 runabout is more graceful. Its running boards are clear from one end of the division to the other. Tool boxes are built flush with the sides; tire-carriers have been eliminated from the boards; gas tanks are no longer omnipresent, quite the contrary in fact, although some are still to be seen.

In facilities for distance work the runabout is far in advance of other years. In almost all of the models, except a few of the smallest variety, special facilities have been supplied for touring. Comfortable seating is one of the elements; larger gasoline storage is another; adequate baggage capacity is still another essential that has been worked out in the current line. The seating and gasoline tanks are details but the baggage carrying is an improvement. In a considerable majority of the cars listed at and above $1,250, provision is made for carrying baggage on the rear deck. This idea is worked out in a variety of ways but the favorite seems to be the compartment, which may be utilized for tire carrying or for the accommodation of a small trunk or suit cases.

The idea of touring in a high-powered runabout is one that is growing steadily.

Mechanically the changes of 1913 are of small importance although rather large in number. The general adoption of electric lighting and the large installation of electric starting devices have resulted in the elimination of battery boxes on the running board and led to their suspension on the frame beneath the body. This has caused a number of rearrangements in the mechanical parts of the automobile. The same may be said for the adoption of central control with its tendency to shorten the leftward reach of the levers.

Cole 50, two passengers, $1,985. 32.4 H.P., 122 WB., 36 x 4 tires.
Cadillac, two passengers, $1,975. 32.4 H.P., 120 WB., 36 x 4½ tires.
Moline M, two passengers, $1,950. 27.25 H.P., 115 WB., 34 x 4 tires.
Pathfinder 13, two passengers, $1,875. 27.25 H.P., 120 WB., 36 x 4 tires.
Hudson 37, two passengers, $1,875. 27.25 H.P., 118 WB., 36 x 4 tires.
Mitchell 2-6, two passengers, $1,850. 33 H.P., 132 WB., 36 x 4 tires.
Schacht KL, two passengers, $1,775. 28.9 H.P., 120 WB., 36 x 4 tires.
Havers 44, two passengers, $1,850. 33.75 H.P., 122 WB., 36 x 4 tires.
Arbenz H, two passengers, $1,825. 27.3 H.P., 120 WB., 36 by 4 tires.
Crawford 30, two passengers, $1,750. 27.25 H.P., 115 WB., 34 x 4 tires.
Abbott-Detroit D, two passengers, $1,700. 27.3 H.P., 116 WB., 34 x 4 tires.
Marathon Champion, two passengers, $1,675. 32.4 H.P., 123 WB., 36 x 4 tires.
Maxwell 40, two passengers, $1,675. 28.9 H.P., 115 WB., 36 x 4 tires.
Rambler, two passengers, $1,650. 32.4 H.P., 120 WB., 36 x 4 tires.

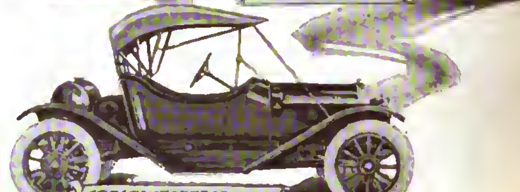
APPERSON 4-45 $1600

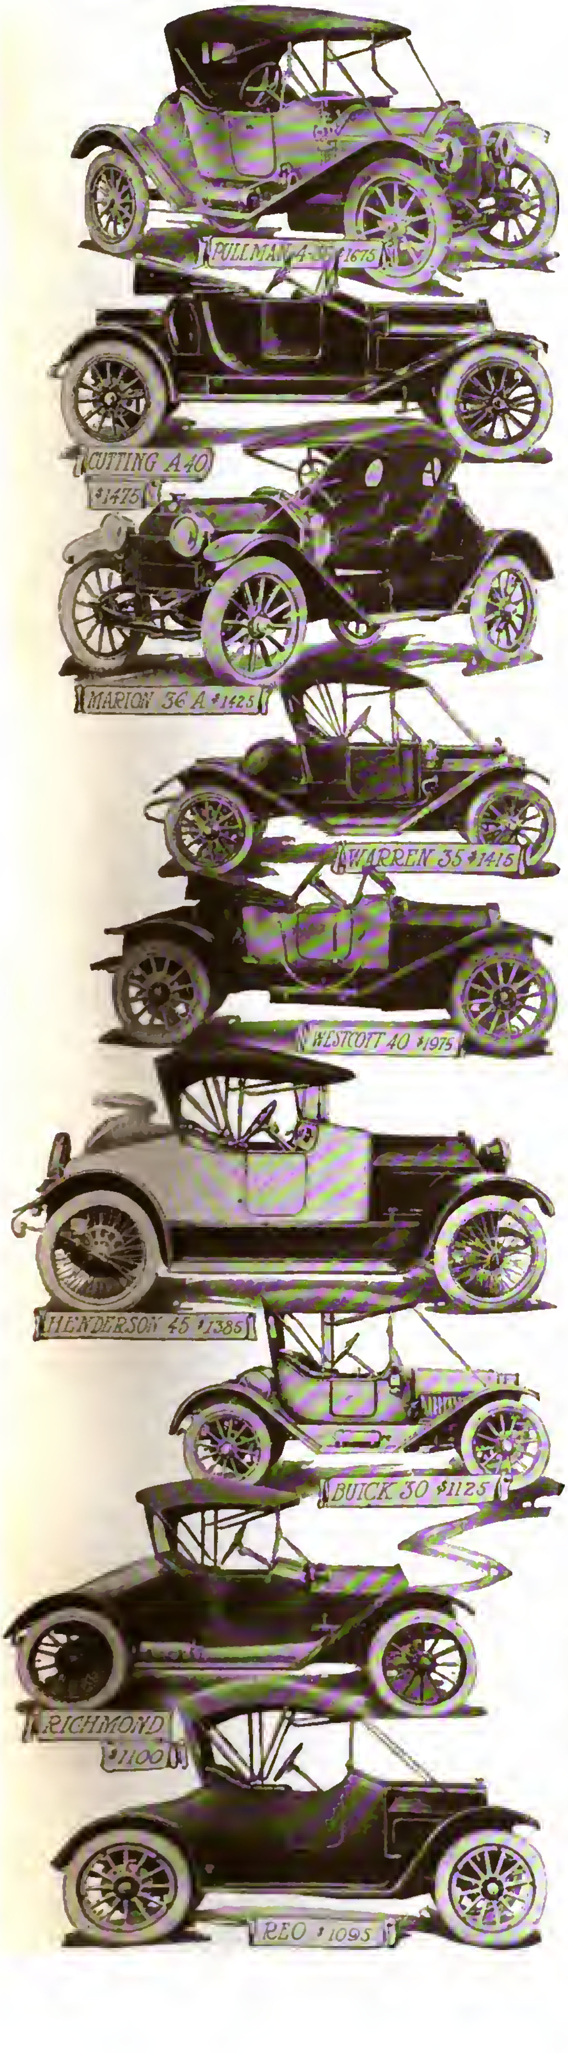
OAKLAND 42 $1600

AMES 44 $1595



GREAT WESTERN $1585

Low Priced Roadsters and Runabouts



DESPITE the fact that wheelbases in the high-priced class are generally longer than last year, the tendency noted hitherto to bring back the motor and place the radiator nearly on a line with the front axle has made little progress.

In average price there has been an advance. While the list price of most of the models is little higher than last year the marked decrease in the number of cheaper cars, the transfer of a few makers of their runabout models from lower to higher-priced classes and the steady price trend noted in the high-priced class, account for the difference.

More equipment is furnished all around than last year and as a general proposition it may be said that the buyer receives more for the same money than he did last year and that in such a view of the industry, prices have actually declined.

In the line of three-passenger, open-bodied cars, 1913 and 1912 stand on the same basis so far as the number of models presented are concerned. There are twenty-three in the 1913 offering and the same number were presented last year. The standard companies in the high-priced class are continuing their models of this type, except that the new cars contain the various detail developments noted elsewhere in the industry as typical of 1913.

In the medium classes much the same condition obtains, but in the low priced class there have been numerous changes. Four companies that included a three-passenger model in 1912 are not presenting one this year, while four new companies have taken their place in the ranks of this class.

The withdrawals and additions in the higher classes about counterbalance.

The three-passenger idea is worked out in several ways. These include the addition of a rumble seat, side seat and the widening of the body to accommodate three sitting abreast.

To a greater extent than applies to any other class of automobile building, the three-passenger type appeals to newcomers, but continued patronage is shown distinctly by the fact that the standard companies retain these models practically unchanged from year to year.

Pullman, two passengers, $1,675. 26.4 H.P., 118 W.B., 34 x 4 tires.
Cutting A-40, two passengers, $1,475. 25.6 H.P., 120 W.B., 36 x 4 tires.

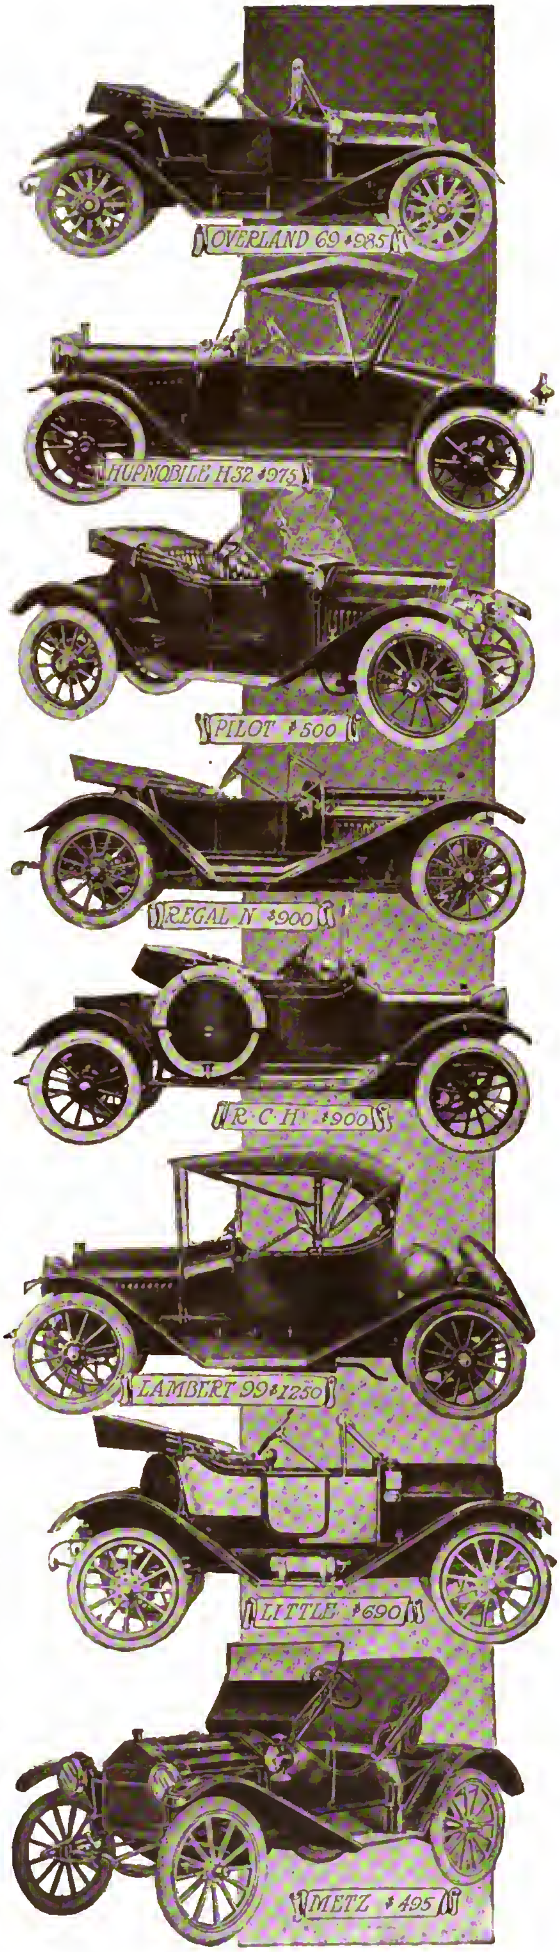
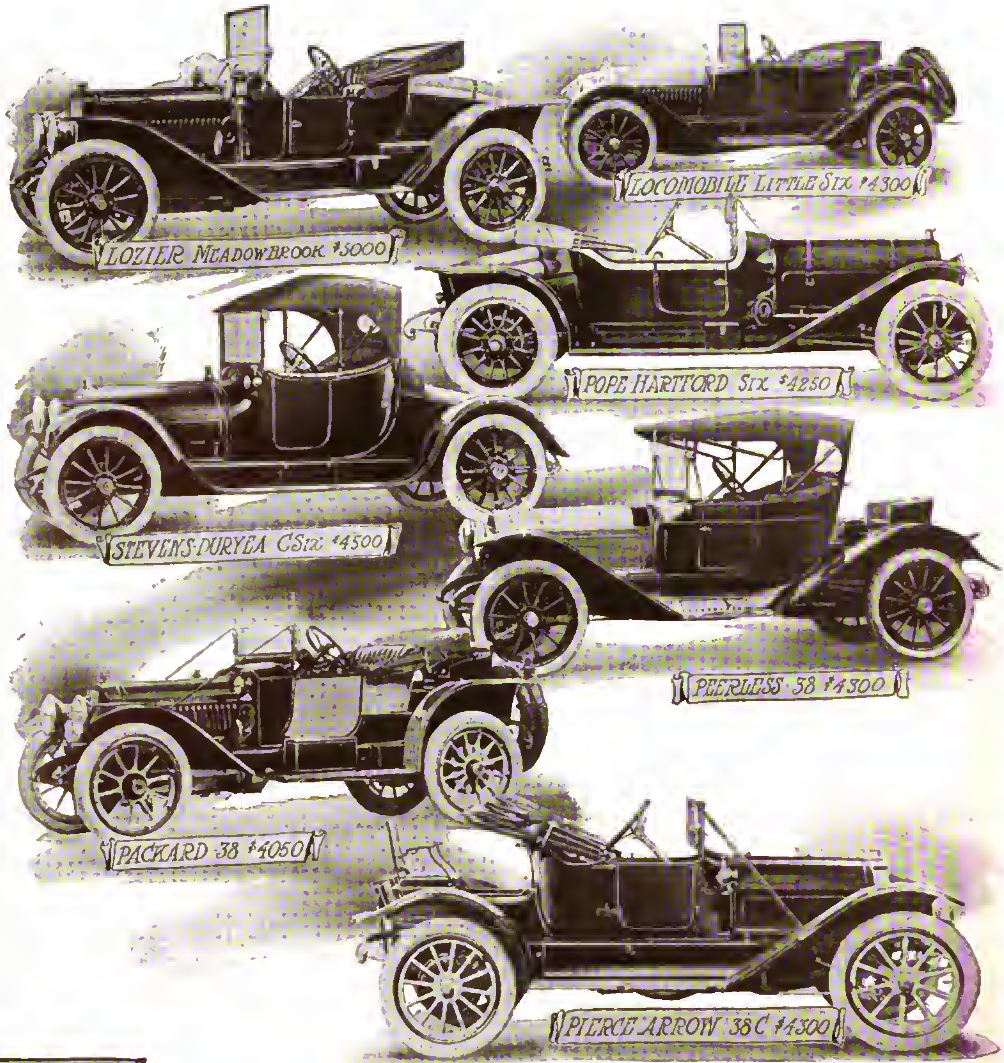
Little, two passengers, $690. 19.6 H.P., 90 W.B., 30 x 3½ tires.
Metz, two passengers, $495. 22.5 H.P., 90 W.B., 30 x 3 tires.



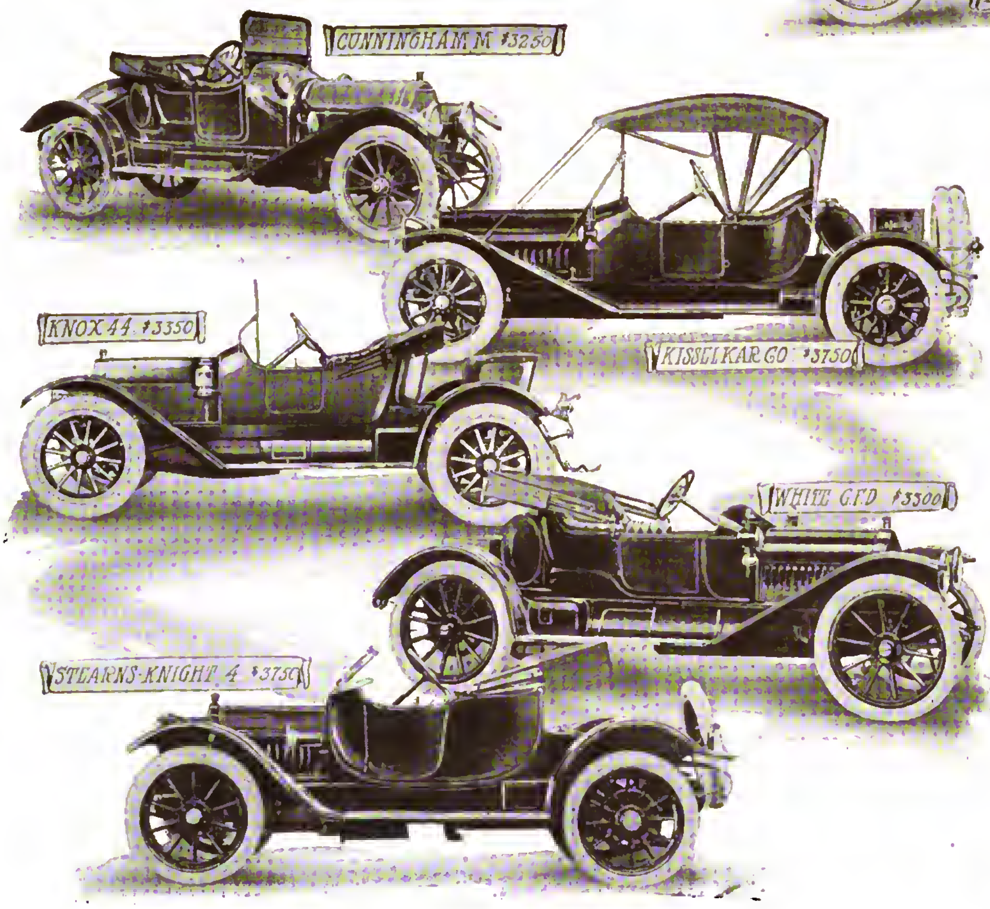
Two Passenger Cars - $3000 and over -



MUSHROOM companies that at an earlier period of the industry sprang up in a night, almost invariably put out two or more runabouts and when the financial blight overtook them for any one of a dozen excellent reasons, the subsequent tabulations of the industry showed the absence of their models. In the 1912 season twenty-six companies retired, accounting for a gross loss of seventy-eight models in the runabout class. At the same time thirteen new makers entered the lists with twenty-three models. On the face of the reports this shows a net loss of fifty-five models but the difference is made up by the weeding and adjustment of the list.

Almost all of the losses in the runabout class were scored in the highest and lowest price divisions. In the low class the losses were caused largely by retirements from business; in the upper class by the elimination of models. In the two middle classes, namely: from $1,251 to $2,000 and from $2,001 to $3,000 the net loss was only eight models. This indicates on even broader lines the tendency toward centralization.

The differences between the runabout of 1913 and its predecessors are mostly developments of innovations introduced in 1912 and earlier in the industry. Inside control is all but universal, although there is still a wide difference in design as to the location of the control levers. A central position for the levers has advanced in favor and is to be seen in a very large percentage of the cars offered. Many models are made with



control at the right side and in a few cases the control is at the left side of the car. Left side drive has been adopted quite generally.

Electric lights are practically universal. Some sort of an engine starter has been installed in nearly all the medium and high-priced cars. The starters are generally electric but there are also gas and pneumatic types.

The cowl is deeper in most models and the streamline effect, so much sought after in body design, is emphasized by the improvement of the cowl this year. Two practical purposes are served, in the first place it protects the instruments on the dash and second, it affords opportunity to install forward gasoline storage which has been accepted by a number of manufacturers.

Cunningham M, three passengers, $3,250. 36.1 H.P., 124 W.B., 36 x 4½ tires.
Kisselkar 60, two passengers, $3,750. 48.6 H.P., 140 W.B., 37 x 5 tires.
Knox 44, four passengers, $3,350. 50 H.P. 122 W.B., 36 x 4½ tires.
White G.F.D., two passengers, $3,300. 28.9 H.P., 120 W.B., 36 x 4½ tires.
Stearns-Knight 4, three passengers, $3,750. 28.9 H.P., 116 W.B., 36 x 4½ tires.
Lozier Meadowbrook, two passengers, $5,000. 51.6 H.P., 131 W.B., 36 x 4½ and 37 x 5 tires.
Locomobile R, two passengers, $4,300. 43.8 H.P., 128 W.B., 36 x 4½ tires.
Stevens-Duryea C, two passengers, $4,500. 46.1 H.P., 131 W.B., 37 x 4½ tires.
Pope-Hartford 29, two passengers, $4,250. 46.1 H.P., 133 W.B., 37 x 5 tires.
Peerless 38, three passengers, $4,300. 38.4 H.P., 125 W.B., 36 x 4½ tires.
Packard 38, three passengers, $4,050. 38.4 H.P., 115½ W.B., 36 x 4½ and 37 x 5 tires.
Pierce-Arrow 38C, three passengers, $4,300. 38.4 H.P., 132 W.B., 36 x 4½ tires.

Runabouts and Roadsters - from $2000 to $3000 -

ROADSTERS or runabouts with seating capacity for two passengers are not presented in such large numbers this year as they were in 1912. The current offerings of the American automobile industry consist of 224 models while last year 276 were on the market.

The reasons for this decline in the roadster type are mainly, the universal tendency toward centralizing manufacturing and selling effort upon a single chassis size, and the retirement from the field of a number of makers whose product consisted largely of two-passenger open-bodied cars.

Dividing the industry into four groups or sections marked out by the selling prices of the runabouts, it will be found that in the class listing at $1,250 and under there are only thirty-three models presented, against sixty-three last year.

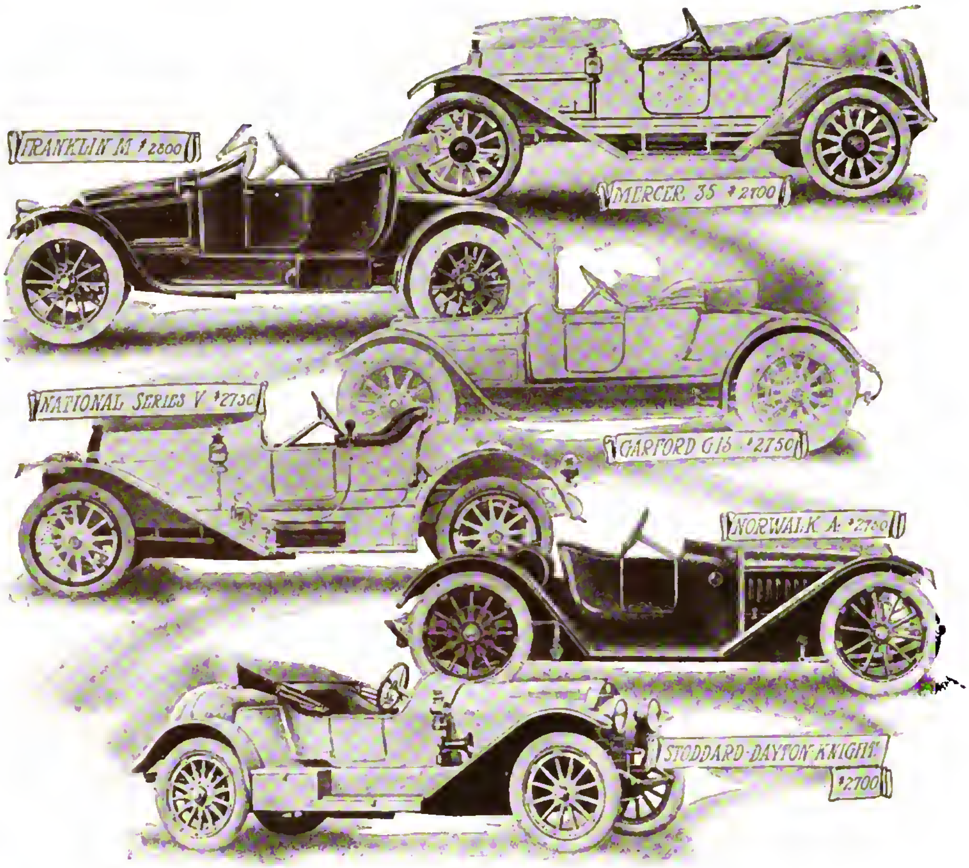
In the class selling from $1,251 to $2,000, there is a net gain of one model, the tables showing seventy-four for 1913 and seventy-three for 1912.

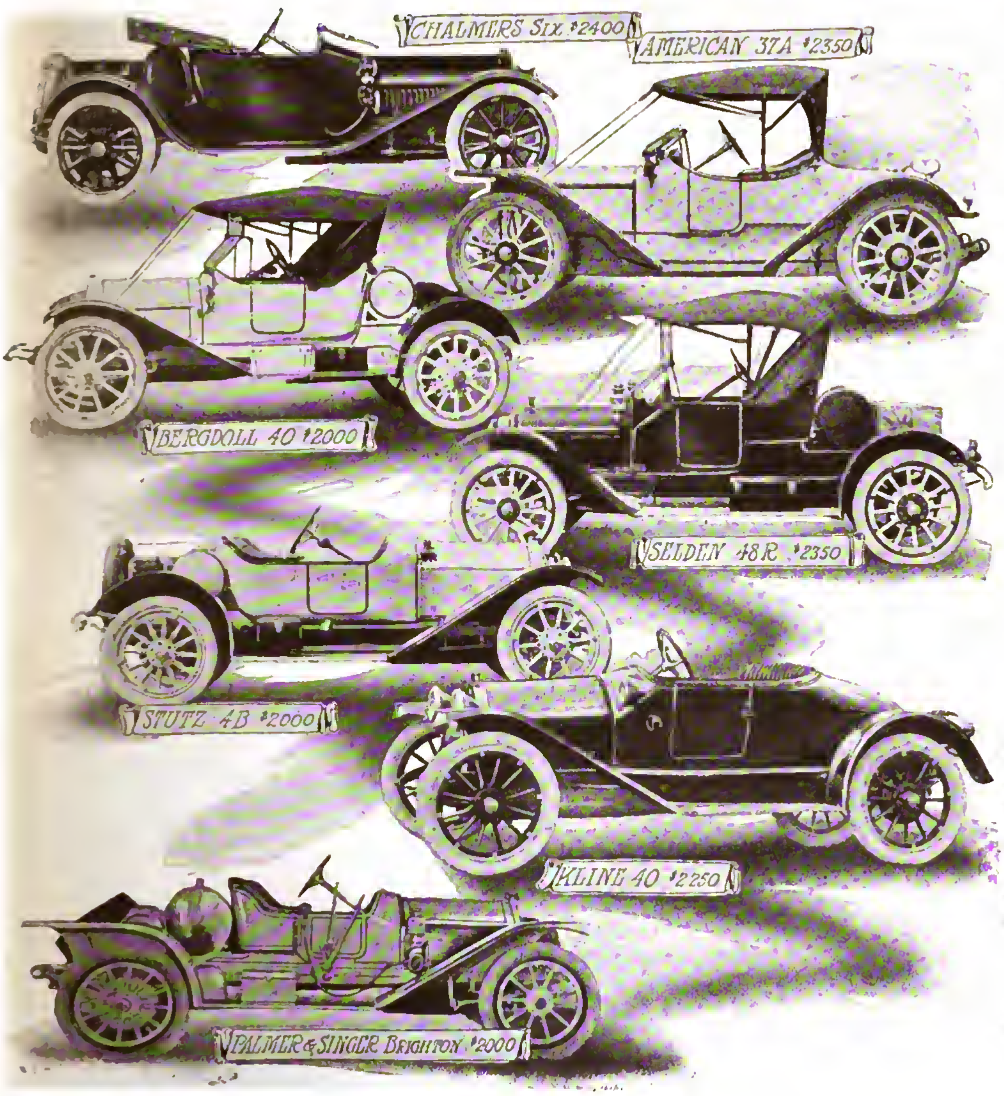
In the $2,001-$3,000 class there are eighty-seven this year and there were ninety-six last year.

Above $3,000 there are thirty models of roadsters listed for 1913 while in 1912 the number was forty-four.

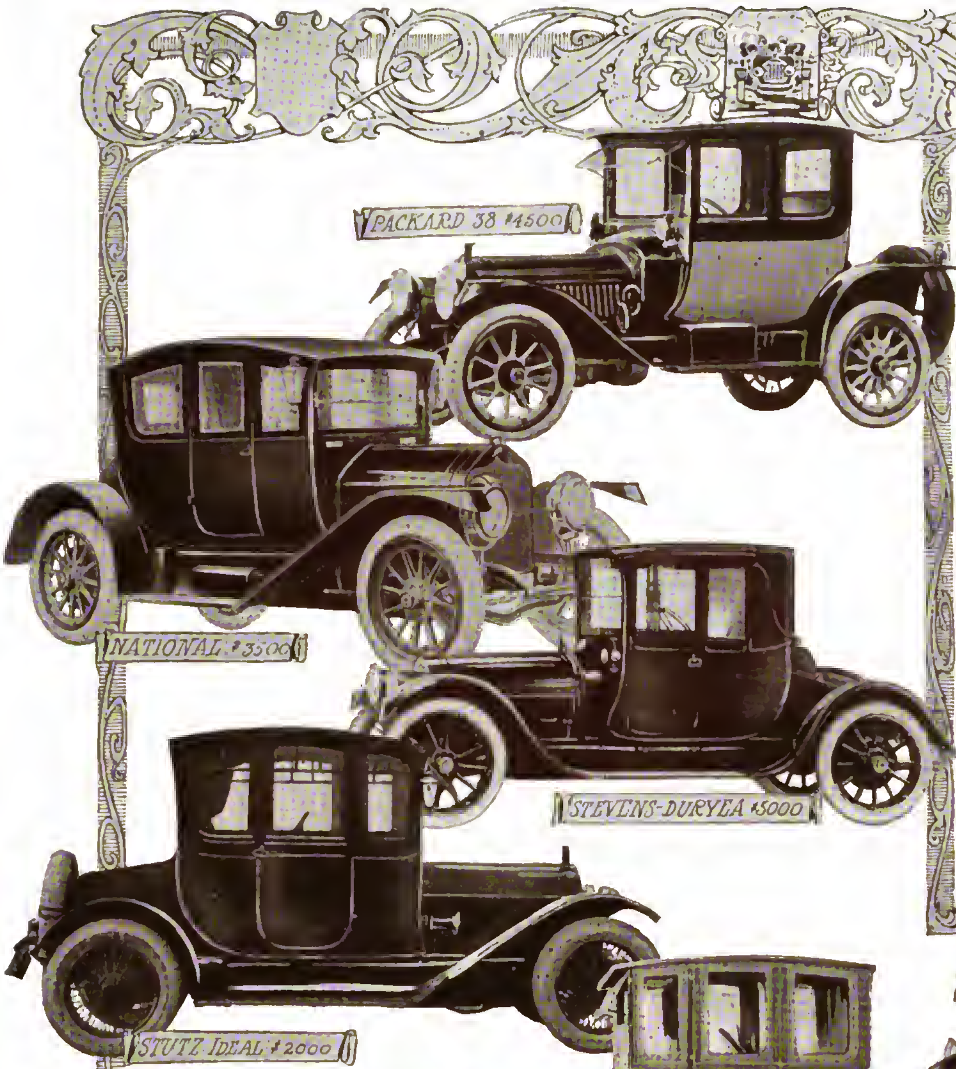
In the process of centralization the manufacturers have eliminated more than a score of models and the remainder are accounted for by retirement of former makers from the field. All told the net reduction amounts to fifty-two models as compared with last year, or a little less than 19 per cent.

The reduction in the number of models does not mean that this type of automobile has been discredited or has lost any popularity. It means only that where a company listed several runabouts last year, the same company is making only one or two types and centering its attention upon them. In a few instances well established companies have discontinued two-passenger open-bodied cars, but it will be found that in almost every instance of that kind the runabout business of the company was of small proportions and the scattering of forces required by a multiplicity of models was too high a price to pay for whatever advantage there may be in putting out a full line including all body types. The fact that quite a material number of those companies that dropped out during 1912, manufactured runabouts, is no reflection against the type.





Chalmers 18, two passengers, $2,400. 48.8 H.P., 180 WB., 86 x 4½ tires.
American 87A. two passengers, $2,350. 82.4 H.P., 118 WB., 87 x 4 tires.
Bergdoll 40, two passengers, $2,000. 25.6 H.P., 121 WB., 86 x 4 tires.
Selden 48R. two passengers, $2,850. 36.1 H.P., 125 WB., 86 x 4 tires.
Stuts 4B, two passengers. $2,000. 86.1 H.P., 120 WB., 34 x 4½ tires.
Kline 40, two-passengers. $2,250. 28.9 H.P., 118 WB., 86 by 4 tires.
Palmer & Singer, Brighton. two passengers, $2,000. 88.4 H.P., 127 WB., 86 x 4 tires.
Mercer 85. two passengers. $2,700. 30.63 H.P., 108 WB., 82 x 4 tires.
Franklin M. two passengers, $2,800. 31.6 H.P., 116 WB., 84 x 4 tires.
Garford G15. two passengers. $2,750. 33.75 H.P., 128 WB., 86 x 4½ tires.
National V. two passengers, $2,750. 38 H.P., 120 WB., 88 x 4½ tires.
Norwalk A. two passengers, $2,750. 38.4 H.P., 126 WB., 38 x 4½ tires.
Stoddard-Dayton Knight, two passengers, $2,700. 36.1 H.P., 122½ WB., 86 x 4½ tires.

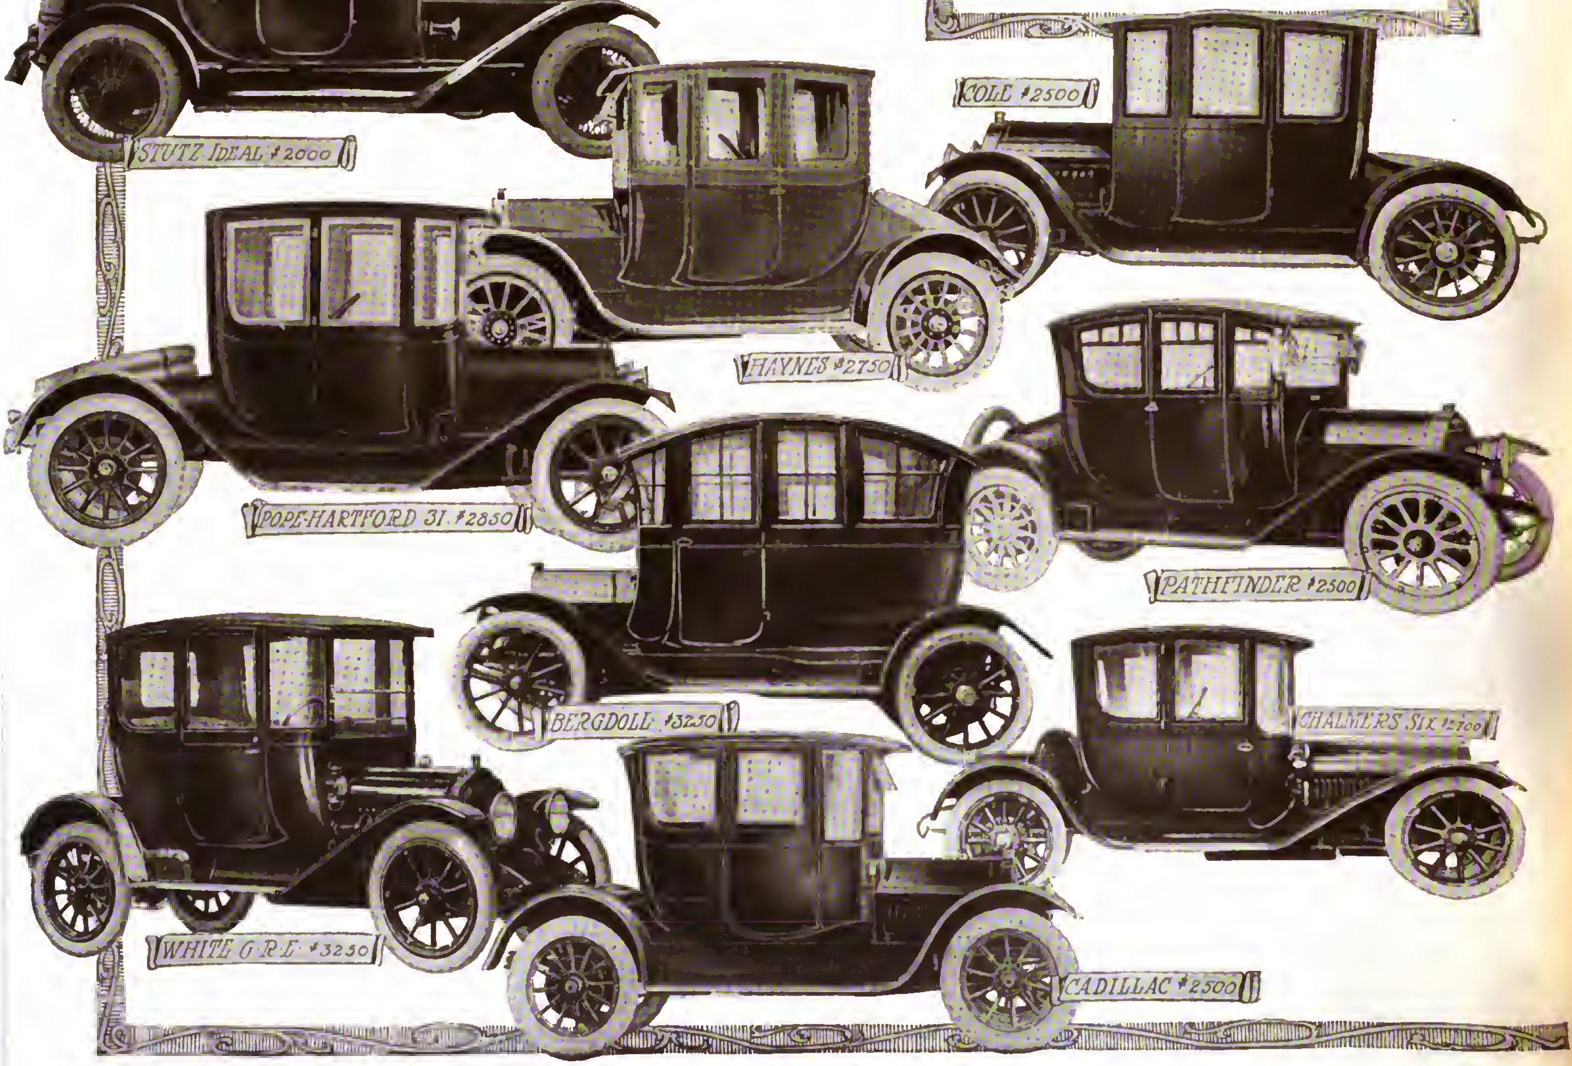


Coupes of Higher Price

IN the coupé types one of the popular trends of the season is encountered. The coupé will be one of the most important cars of 1913, as foreshadowed by the interest taken in it by the manufacturer.

For 1913 the industry presents fifty-two models and the $2,000-$3,000 class only shows a loss in the number of models.

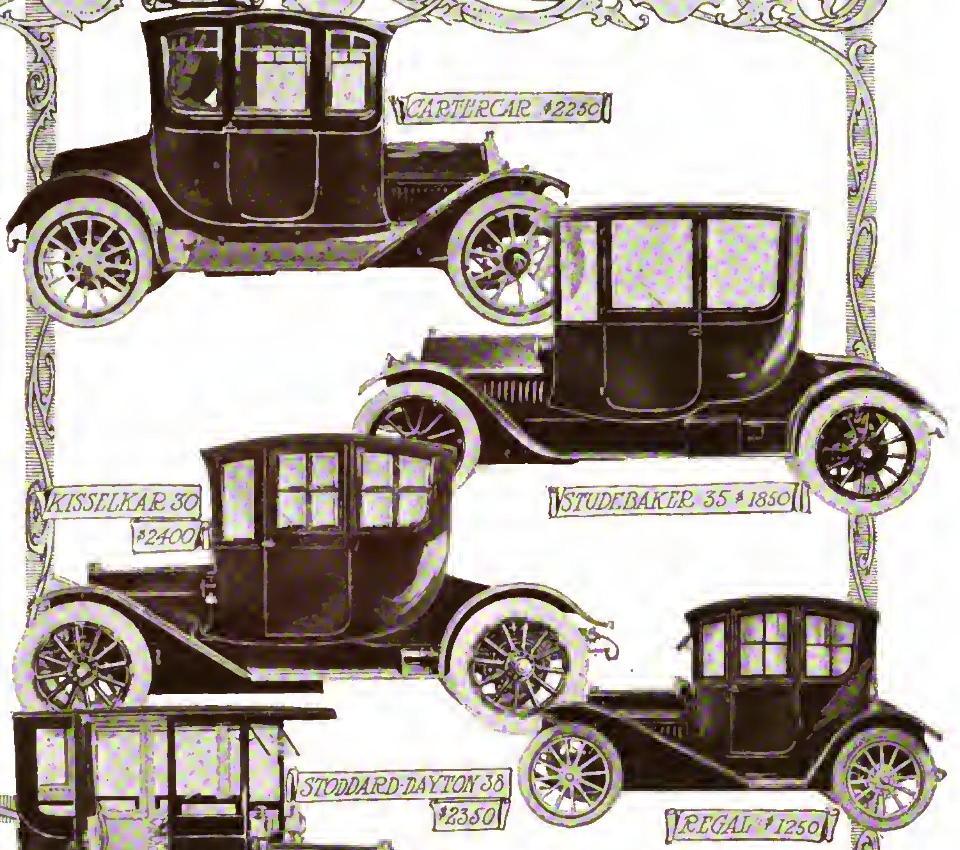
Packard 38, $4,500. 38.4 H.P., 115½ W.B., 36 x 4½ and 37 x 5 tires.
National V, $3,500. 38 H.P., 128 W.B., 36 x 4½ tires.
Stevens-Duryea, $5,000. 46.1 H.P., 131 W.B., 37 x 4½ and 37 x 5 tires.
Stutz, $2,000. 36.1 H.P., 120 W.B., 34 x 4½ tires.
Cole, $2,500. 32.4 H.P., 122 W.B., 36 x 4 tires.
Haynes, $2,750. 32.4 H.P., 120 W.B., 36 x 4½ tires.
Pope-Hartford 31, $2,850. 30.1 H.P., 118½ W.B., 36 x 4½ tires.
Pathfinder 13, $2,500. 27.25 H.P., 120 W.B., 36 x 4 tires.
Bergdoll 40, $3,250. 25.6 H.P., 121 W.B., 36 x 4 tires.
White GRE, $3,250. 22.5 H.P., 110 W.B., 34 x 4 tires.
Cadillac, $2,500. 32.4 H.P., 120 W.B., 36 x 4½ tires.
Chalmers 18, $2,700. 43.8 H.P., 130 W.B., 36 x 4½ tires.

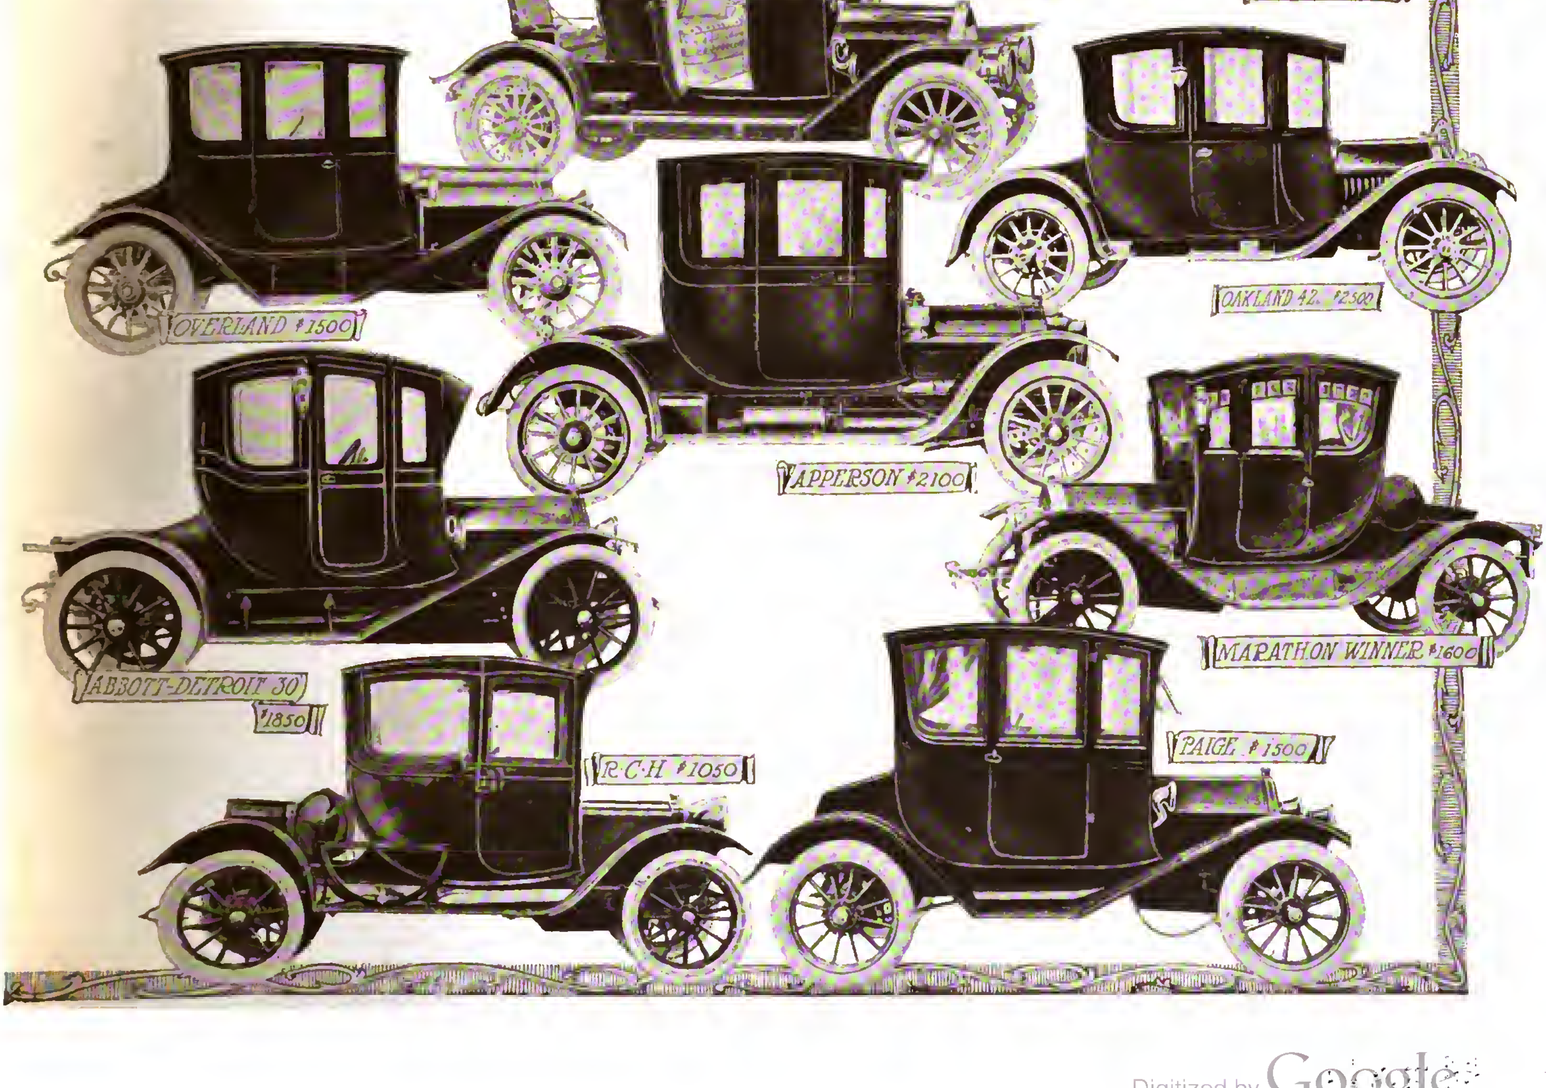


Medium Priced Coupes

IN the high-priced class the increase is remarkable, as in 1912 there were only four models of coupés offered, while this season the list contains nineteen models. In the $2,500 class the loss is more apparent than real, for included in its list are five sedan models, which are simple enlargements of the coupé types carried in 1912. In the $1,500 class a large increase is shown.

Cartercar 5, $2,250. 27.25 H.P., 116 W.B., 36 x 4 tires.
Studebaker 35, $1,850. 27.25 H.P., 115½ W.B., 34 x 4 tires.
Kisselkar, $2,400. 32.4 H.P., 121 W.B., 35 x 4½ and 35 x 4 tires.
Regal, $1,250. 22.5 H.P., 100 W.B., 32 x 3½ tires.
Stoddard-Dayton 38, $2,350. 28.9 H.P., 114 W.B., 35 x 4½ tires.
Overland 69, $1,500. 25.6 H.P., 110 W.B., 32 x 3½ tires.
Oakland 42, $2,500. 27.25 H.P., 116 W.B., 34 x 4 tires.
Apperson 4-45, $2,100. 32.4 H.P., 114 W.B., 34 x 4 tires.
Abbott-Detroit, $1,850. 27.3 H.P., 116 W.B., 34 x 4 tires.
Marathon Winner, $1,600. 28.9 H.P., 116 W.B., 34 x 4 tires.
R.C.H., $1,050. 16.9 H.P., 110 W.B., 32 x 3½ tires.
Paige, $1,500. 22.5 H.P., 110 W.B., 33 x 4 tires.





The Check Book and the Cars

Full Pocket-Book Class

Costing Over $3000

PROSPECTIVE purchasers of 1913 cars of high-class manufacture will be confronted with the products of no less than forty-eight factories, ranging in price between $3,000 and $7,250. These cars represent the cream of American automobile engineering, body building and equipment. Fully 360 models are offered to the public and almost one-fourth of these are limousine equipped, indicating the rapidly increasing degree in which this splendid type of body attracts automobilists and showing that comfort is among the chief requirements of an expensive car. Besides eighty-seven limousines there are fifty-eight seven-passenger touring cars, forty-one five-passenger touring cars, thirty-six roadsters and thirty-one landaulets; while the remainder of the body styles is made up by three- and four-passenger touring cars, broughams, phaetons, coupés, runabouts and a variety of so-called fancy styles.

Next to comfort, power is a leading consideration in selecting a quality automobile. The cars shown this year vary in horsepower from 60.50 to 25.60, these sizes referring to the five-cylinder Adams-Farwell and the new Edwards-Knight, respectively. The average horsepower of the high-priced 1913 car is 39.49.

(*Continued from page* 100.)

Motors for the year 1913 include ninety-one power plants, eighty-six of which are of the long-stroke type; in other words, the makers of 95 per cent. of the high-priced automobiles have become convinced of the often-elaborated advantages of long-stroke designs. Only one car in this class has a short-stroke motor, and four square motors are in use. Among the long-stroke designs, the Lozier 77 motor ranks foremost, with a stroke-bore ratio of 1.51, being followed by the Bergdoll 40, 1.48:1, and Peerless 37 and Pierce 6-66, both with a ratio of 1.4:1. The smallest ratio is that of the Adams-Farwell cylinders, namely .91:1. The practical progress made by the Knight motor, so far as the number of manufacturers is concerned, is rather modest; in addition to Stearns, Atlas, Columbia and Stoddard-Dayton, one company, the Edwards, has taken up the manufacture of the sleeve-valve motor, so that now nine models of cars equipped with the silent Knight power plant are on the market. The six-cylinder power plant constructions have gained in numbers and now compose forty-seven of the motors on hand, or 52.5 per cent., while there are forty-three four-cylinder designs and one five-cylinder, rotary motor.

Another respect in which automobile luxury has been augmented is the wide use of electric lighting-generator outfits in this class of cars. This type of outfit has made most remarkable strides since last year and is today almost universal in the $4,000 class of automobiles. Together with several battery lighting outfits it has entirely supplanted the acetylene tank and headlights in this department of the show. A most scrutinizing inspection has revealed the fact that of the fifty-eight makes included in this class, fifty-three, or 91 per cent., are fitted with electric lighting generators of perhaps a dozen makes. Five makes of automobiles are equipped with storage batteries to be charged at the garage for lighting purposes.

The Pierce-Arrow 66-A is the leader in wheelbase length, with 147.5 inches, being followed by the Marmon Six with 145 inches and the Norwalk with 144 inches. There are a number of 140-inch cars and a host of such having wheelbase lengths from 130 to 130 inches. The shortest wheelbase is that of the Alco 7-16 landaulet, namely, 104 inches. As heretofore, the standard tread has been preserved at 56 inches in the majority of cases, with exceptions or options at 60 inches.

As regards tire sizes, the American, formerly the leader in large wheels, has been superseded by the Norwalk, a newcomer, with 41 by 5-inch tires. The most common tire size in this department is still 36 by 3.5 inches, but a number of 37 and 38-inch tires have been introduced this year.

One of the questions which have been in the foreground during 1912 is that of the position of the steering wheel. A vigorous campaign in favor of the left-hand steer has been conducted during the past twelvemonth, and as a result, fourteen companies out of fifty-eight, or 24 per cent., have introduced the left-hand control on their automobiles.

A comparison between the cars listed in the $4,000 class and those enumerated in it a year ago shows many changes. There are thirteen companies listed in this department for the first time, some of whom appear for the first time.

CHEAP CARS, that is, cars selling at $1,250 and less, are the products of thirty-one makers. Seven of these are new in their class, they being the Detroiter, Mason, Perfex, Gleason, King, Lambert and McIntyre. The companies who have ceased to manufacture low-priced cars are twenty-seven, and among them are the makers of Brush, DeTamble, Jonz, Cutting, Jackson, Mitchell, Schacht, Cartercar, Herreshoff and Elmore.

The average power plant is a four-cylinder, water-cooled motor, with a stroke-bore ratio of 1.21:1, while last year's ratio was 1.15:1. The practice of casting enbloc prevails as it did last year, and if anything has gained followers. The average horsepower is 21.51 as against 21.18 last year, but the actual rating of the motors varies from 11.25 (Motorette) to 28.90 (Only). The thirty-six power plants used by the thirty-one makers in this class include thirty-two four-cylinder motors, three two-cylinder and one six-cylinder power plant, the Cameron 30. Out of all these motors only four have bores and strokes of equal length and two the stroke shorter than the bore. Poppet-valve motors are used without exception.

The wheelbase has been slightly lengthened for 1913, giving an average of 104.2, while last year this dimension was 104 inches. The Motorette has the minimum wheelbase, 74 inches, while the maximum of 114 inches is that of the Cameron Flyer. Tires vary in size from 28 by 2.5 inches for the front and 28 by 3 inches for the rear (Motorette) to 34 by 4-inch all-around equipment as used by Buick and Reo cars.

Nine companies out of thirty-one, or 29 per cent., use the left-hand control at least on part of their models. This speaks volumes for the alertness of the manufacturers of small cars who are quick to see advantages of construction and to utilize them in order to increase the comfort of their customers. The public has shown great favor toward the left-hand control, and considering that Ford, R-C-H, Reo the Fifth and Maxwell are equipped with this type of control, it may safely be said that a very considerable portion of the total 1913 output of automobile factories will be equipped with the left-hand steer.

More conservatism, however, is displayed in respect of the lighting equipment, which has also been a pertinent problem during the past two years. In the small-car class acetylene lighting has remained prevalent, and only Auburn, Oakland and Halladay use electric lighting generators, while nine companies include storage batteries in their equipment. In other words, 61 per cent. of small-car makers use acetylene headlights.

There are seventy-seven different models in the $1,000-car class, which belong to twelve types, according to the bodies used on them. The majority of these are roadsters and five-passenger touring cars, numbering twenty-six and twenty-four respectively, or 33.8 and 31.2 per cent., respectively. Furthermore, ten runabouts, and six four-passenger touring cars, as well as four coupés, are offered in this class, while there is one car equipped with each of the following body types: towncar, demi-tonneau, suburban, victoria, surrey, buggy, flyer. Thus, out of seventy-seven models only five are fitted with closed bodies, so that 93.5 per cent. of the low-priced cars are open to the air; this condition is characteristic of low-priced cars today, as is brought out strikingly by a comparison with the figures given in con-condition is characteristic of low-priced cars today.

IN REVIEWING the $1,500 car several striking points come up. For one thing, this group contains almost exclusively cars having decidedly long-stroke motors, with an average bore slightly less than what it was last year. Consequently the average horsepower rating according to the S. A. E. formula is less than what it was a year ago; while as a matter of fact an actual power increase has been realized in the cases of most cars. The wheelbases have been lengthened, and many firms have introduced electric lighting, left-hand control, self-starters and other appliances which tend to increase comfort.

To be exact, the average motor in this class has the following characteristics: Bore, 4.13 inches, stroke, 5 inches, ratio, 1.21:1. The cylinders are cast in pairs and water-cooled. The average horsepower is 28.81, while in 1912 it was 30.01, when the stroke-bore ratio was 1.14:1. The actual maximum and minimum of horsepower on this class are 36.10 (Imperial 44) and 16.90 (R-C-H). As a matter of fact, there are 110 power plants used by the seventy-nine companies making cars which range in this class, and 106 out of these 110 have a stroke-bore ratio greater than 1.1, while the other four motors are square, so-called. Ninety-nine engines are of the four-cylinder type and eleven are six-cylinder designs.

The increased length of the chassis is evidenced by the average wheelbase being 118.4, or 2.4 inches in excess of what it was last year. The longest wheelbase in this class is that of the Burg, namely, 134 inches, while Franklin and Regal with 100 inches each are tied for minimum wheelbase. Tire sizes range from 32 by 3.5 inches to 36 by 4.5 inches.

Each of the seventy-nine makers manufactures, as an average, three models, a total of 213 different models, as follows:

Five-p. touring............	100	100	Fore-door body................	3
Roadster	57	57	Six-p. touring..................	2
Runabout	22		Phaeton	2
Coupé	12		Speedster	2
Four-p. touring...........	11		Semi-racer	2
Seven-p. touring..........	6		Two-p. touring.................	1
Torpedo	7		Demi-tonneau	1
Toy tonneau...............	4		Semi-touring	1

The prevalence of five-passenger touring cars which compose 43 per cent. of the models offered at this time is remarkable and indicates that a very large portion of touring cars are recruited from this class of automobiles. In fact, the touring cars of the $1,500 class compose 28.5 per cent. of all the touring models announced for 1913. Only 5.4 per cent. of the cars in this class, namely, the coupés, are closed designs. Eighty-four models, or 36.2 per cent., of the 232 models, are two-passenger designs.

Nineteen out of the seventy-nine companies have equipped their products, or at least part of them, with left-hand control. This means 24 per cent., and together with two companies making the left steer optional, 26 per cent. of the $1,500-car manufacturers. A similarly progressive position has been taken by the makers of this class of cars in equipping 80 per cent. of their output with electric lights, 52 per cent. of the makers using generators and 28 per cent. batteries only.

While twenty-three manufacturers who were represented in this class last year have disappeared from the class list, twenty-five new ones have come up instead. Actually new among these are the manufacturers of the following cars: Henderson, Mason, Nyberg, Omaha and Pacific Special.

THE CLASS of medium-priced cars averaging at $2,500 comprises 219 models manufactured by seventy-nine makers and equipped with 100 different power plants. As in the case of the $1,500 cars, the average S. A. E. horsepower is smaller than in 1912, the reason being the same in both classes of cars.

Only two square motors are found in this class, ninety-eight being long-stroke designs; the average S. A. E. horsepower is 34.3, compared with 35.45 in 1912. The average stroke-bore ratio has been increased 7 per cent., being now 1.209:1, while in 1912 it was 1.13:1. All the motors in this class are poppet-valve designs of the water-cooled type, and four and six-cylinder power plants are almost evenly divided, the former numbering fifty-three and the latter forty-seven. The actual horsepower varies from 22.5 (White GRE) to 48.6 (Pullman 6-66).

The wheelbase has also been lengthened 5.7 inches, being now 125.7 inches. The maximum and minimum wheelbases, however, as actually used in the cars, range over a space of 40 inches; the Franklin G having 103 inches and the Mitchell 7-6 144 inches. The tire sizes, too, cover a wide range. Mercer and Franklin G cars, fitted with 32 by 4-inch tires all around, represent the minimum dimensions in this respect; the new Norwalk car leads by its 38.5 by 4.5-inch wheels.

Twenty-one makers have made the left-hand steer stock equipment and three have made it optional, so that twenty-four manufacturers, or 30.6 per cent. of the whole, offer left-hand control to their customers. This is the largest percentage among the makers of any class. The reason is that the man who buys a car for from $2,000 to $3,000 demands comfort.

As in the $1,500 car class, which also includes seventy-nine makers, the automobiles in this class are rapidly being equipped with electric lighting outfits. As in the $1,500 car class, sixty-three makers out of the seventy-nine use electric lights, but on the $2,500 cars the generator equipment is much more frequent than on the cheaper cars, being used on fifty-seven cars, so that only six makes are fitted with batteries. As for self-starters, visitors of the shows will see for themselves how common this equipment has become for the new year.

Among the various bodies shown, the five-passenger touring cars and roadster designs are about equal in number, the first being represented by fifty-four and the latter by forty-nine makes. There are thirty-three seven-passenger touring cars and thirty-two four-passenger touring cars, and the next place is taken by seventeen coupés. Besides eleven six-passenger touring cars, there are a few limousines, runabouts, landaulets, town cars, sedans, torpedoes, speedsters, phaetons, etc.

While in this class there are eleven new names, including A. E. C., Burg, Carroll, Holly, Moyer, Norwalk and Nyberg, as well as new products of the makers of Hudson, Garford, Flanders and Duquesne, forty makers who formerly made cars selling at from $1,750 to $3,000 have discontinued these cars or have gone out of business altogether. The former include National, Overland, Stevens-Duryea, Studebaker, Halladay, Everitt, Autocar, Amplex, Cutting, Marathon and Warren, etc. Among the companies who have dropped the making of automobiles are the former manufacturers of Corbin, Johnson, Jonz, Otto, and Standard.

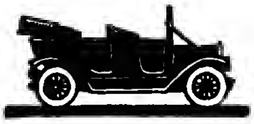
Brain Products

Being a Company-by-Company Story of All 1913 Cars, Listing Their Changes, Lines of Development and the General Tendencies in Chassis and Bodies

By J. Edward Schipper



Practice

¶ In the following pages The Automobile presents its descriptive and illustrative review of the majority of the automobiles listed for the 1913 market. For general conveniences these summaries of changes in design, for such they really are, are in alphabetical order with a few exceptions.

¶ These summaries tell the progress story as exemplified in the 1913 products. Every detail change is not enumerated, but the leading trends are indicated.

¶ There is scarcely a concern that was building in 1912 that has not listed some changes for this year. In spite of the many announcements against annual models it is a fact that such concerns have incorporated changes by way of lighting or starting systems, and in nearly every case there has been an effort to have these changes settled and incorporated in the old models before the commencement of the show circuit.

¶ An exemplary trend in new models with not a few concerns is the aim at standardization of parts for two or more models, so that the same cylinder castings can be used for four or six-cylinder models; besides, the factory operations on corresponding parts in different models are simplified, all with the one aim of decreasing the cost of production.

¶ There has been an avalanche toward starting and lighting systems using electricity, and the installation of such outfits has necessitated not a few motor changes in flywheels, manifolds, camshaft and pumpshaft drives and disposition of timing and motor gears.

¶ Throughout the entire gamut of manufacture there is a pronounced tendency toward reduction in the number of chassis models. With a few there has been a wholesale cutting from four or five models last year to a single one for this season; but again there are a few companies that list more models than last season, due primarily to the introduction of new models without the immediate discontinuance of some of the old ones. The reduction in number of models has made itself conspicuous with several makers of very large outputs, these finding it imperative to reduce the number of models in order to get the output.

—

Abbott—Adds New Model

There are two Abbotts on the market for 1913. These are the 44-50, which is practically unchanged from last year, and the 34-40, which is a new model. The new model is of somewhat different design from that incorporated in the line for 1912. In the first place, the valve-in-the-head motor has been replaced by an L-head monobloc. Besides this the adoption of the underslung spring construction on all models along with an electric starting device, are added features. The starting system is entirely independent of the electric light generator and magneto. It is designed especially for the Abbott cars and is driven by a current taken from a storage battery which is mounted under the car body near the rear of the frame. This battery has a capacity of 180 ampere-hours. It is charged by the lighting generator. Underslinging the springs all around on all models has made no difference in the appearance of the cars.

Alco—Adopts Disk Clutch

A new dry-plate clutch has been installed in the 1913 Alco. It is of multiple-disk design, the driving disks being faced with high-friction material which bears against driven disks of saw-steel. The new clutch as compared with the one formerly used has seven driving disks against twenty-four; eight driven disks of steel against twenty-five of bronze. The driving pins and lugs are the same in both types of clutches, but when the spring thrust is engaged in the new type the pressure is only 344 pounds against 395 for the old; released, the new 420 against 485. Pressure required on the pedal to release the new clutch is 36 pounds, while under the old system it required 75 pounds. The area of the clutch brake is 8.85 inches against 3 inches before. Aside from that single change in the mechanism, the difference between the current Alcos and those of 1912 consist of body developments and added comforts and luxuries. The curved roof of some of the inclosed bodies, an electric searchlight on the windshield for night touring, artistic doors, slightly wider and trimmer than last year's model even, deeper upholstery, electric light under the door on the curb side of the body to show the running board when the door is opened, a disappearing window at the back of the front seat in the closed cars, a tell-tale gasoline gauge and a few other details are noted.

Alpena—Adds a Six

A single six-cylinder model will be produced by the Alpena Motor Car Company for 1913. The motor is the Rutenber six-cylinder type, with cylinders 3.75 by 5.25, cast in pairs. The valves are located on the left side, their springs and tappets inclosed by cover plates. The motor is suspended on three points. The clutch is of the faced multiple-disk-in-oil type, the facing being Raybestos. The three-speed selective gearset is located amidships, and drives the floating rear axle through a Spicer shaft. A 135-inch wheelbase and 36 by 4-inch tires are used, the tires being mounted on Baker demountable rims. One spare is furnished. The car is electrically lighted and started by a dynamo and storage battery which also furnish current for ignition. This is the second season that this has been done. Right-hand drive and center control are featured, with nickel trimming throughout. Full equipment is furnished.

American—Better Equipped

Three models of American are known as the Traveler, Tourist and Scout. The use of the underslung construction is to be continued this season. The Traveler chassis comes in two sizes, one with 140-inch wheelbase, the other with 124 inches; 41 by 4.5-inch tires front and rear on demountable rims are used in this model. This is one of the largest wheels on the American market for this season. Small refinements in this model are noticed which may be mentioned, these are, the inclosing of the space between the body and the running boards, housing the forward shackle of the rear springs and more complete equipment. The latter includes specially constructed adjustable mohair top, top booth and curtains, a combination lighting dynamo and electric starter supplying current for all five lights, Warner combination clock and speedometer. The Tourist model continues the same as last year except that the body has been widened 2 inches, pockets have been placed in the tonneau doors, a glove box placed between the two front seats, and electric light installed on the left fender and a license bracket on the right. The former ratchet spark and throttle control has been replaced by one of the friction type. The little Scout is the newest model. and has the fewest changes, these taking the shape of better equipment.

Ames—Uses Bloc Motor

Two models are being put out for the 1913 season by the Ames Motor Car Company. One is a touring model known as the 45 and the other a roadster known as model 44. Both these are mounted on the same chassis. The Continental four-cylinder en bloc motor is incorporated in this design. It has a bore of 4.125 inches and a stroke of 5.25 inches. The cooling circulation is maintained by centrifugal pump. One of the features of the new model is the Gray and Davis electric lighting and starting outfit used in connection with Willard storage battery. The clutch and gearset are a unit with the motor, the casing being integral with the rear end of the crankcase. For 1913 the new Schebler model O carbureter has been adopted. The clutch is of the multiple disk type with alternate disks lined with Raybestos. Control levers are attached directly to the gearset housing giving center control. The drive is by a shaft carrying two Spicer universal joints, one at either end. The pressed steel torque arm is distinct and separate from the drive. The rear axle is floating and the differential is carried on annular ball bearings. A slight improvement has been made in the gasoline tank, which although still located beneath the front seat may be filled without removing the seat cushions, the filler pipe coming up through the glove box in the partition between the two front seats. The bodies on both models are all steel. One of the features of the body is a flush handrail or moulding running all the way round the car.. This moulding instead of being fastened to the body with screws is attached underneath the outside covering, thereby securing a perfectly smooth top surface.

Apperson—Abandons Yearly Models

One more firm, that of Apperson Brothers, has abandoned the yearly model idea, producing on the series plan, making improvements as designed without reference to the time of the year. The 1913 series is almost identical with that of 1912. Full equipment is included in the standard price, with the optional features of electric starter and electric lights. The line includes all five of last year's models, three of which are of 45 horsepower and two of which have a 55-horsepower motor. Both motors are of the four-cylinder type with valves on opposite sides and have hollow crankshaft oiling system.

Auburn—Adds a Six

Five models constitute the Auburn line for 1913. Two of these are continuations of last season's models. Two sizes are offered, one the 6-50, a continuation, and the other the 6-45, a new model. Last year's 40-N is this year's 40 L, while the 35 L and the 30 L have been supplanted by the 33-L and the 37 L. No change has been made in the 6-50 except the addition of the Ward-Leonard lighting system as regular equipment. The new six employs a long-stroke motor, 3.75 by 5.5, with valves on the left side. The clutch is of the leather-faced cone type, and the gearset of the three-speed selective variety. A floating rear axle is used, and 36 by 4-inch tires. The wheelbase is 130 inches. The wheelbase on the 40 L is 122 inches, 2 inches longer than on last year's car. The tires this year are 36 by 4

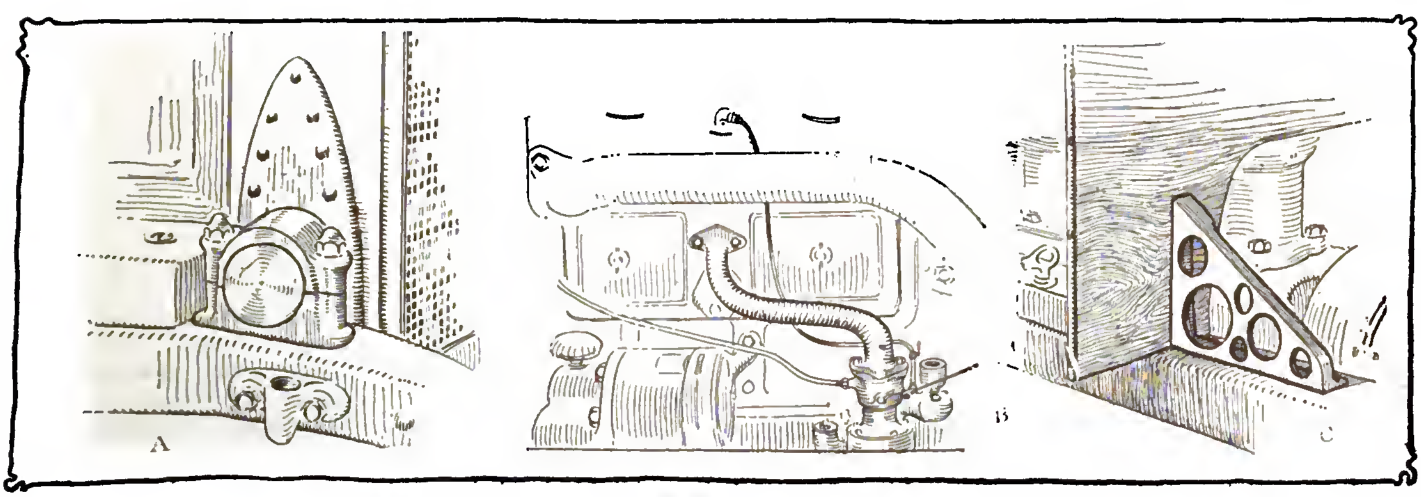


Fig. 1—A, Alco radiator suspension; B, Abbott intake manifold; C, Alco dash bracket

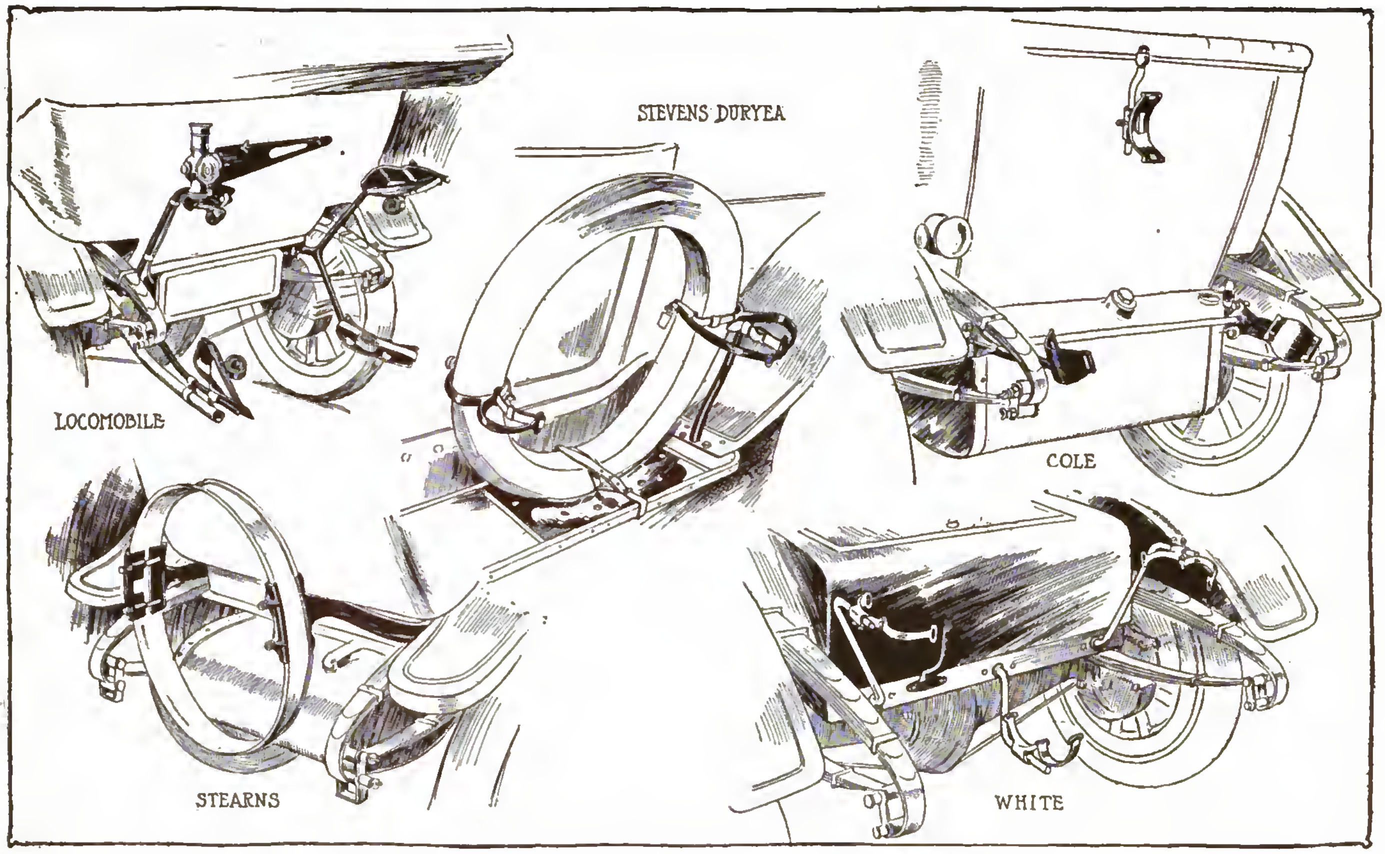

Fig. 2—Rear tire carriers are becoming more popular than ever before

against 37 by 4 in 1912. Model 33 L uses the new Rutenber 3.75 by 5.5 four-cylinder block motor with valves on the left side. A leather-faced cone clutch and three-speed selective gearset are used, the rear axle being of the floating type, on Hyatt roller bearings. The wheels are 34 by 3 1-2 inches all around with a 112-inch wheelbase. Model 37L has a motor 4 1-4 by 4 3-4, of the mono-block type, with valves on the left side. A multiple-disk-in-oil clutch and three-speed selective gearset are included in the unit power plant, and the floating axle is equipped with ball bearings throughout. The wheelbase of this model is 115 inches, and the tires are 35 by 4. The Remy magneto, Schebler carbureter, Rutenber motor and Ward-Leonard electric lighting system are used on all models.

Amplex—Four-Cycle Six

A completely reorganized line has been put on the market for 1913 by the Amplex company. The two-cycle type formerly made under the name of Amplex has been discontinued as a stock production. The new chassis is a six-cylinder with the cylinders cast in pairs. It has a bore of 4.125 inches and a stroke of 5.25 inches. Among the important features on this chassis are the use of the Northeast lighting and starting system and rear axle gearset. It is stated that the Amplex company will shortly bring out a Knight motor.

Austin—Has Two-speed Axle

No marked changes other than the new two-speed Austin axle will be noticed in this concern's line which consists of three models of sixes. This year they are known as the models 77, 66 and 55, they are all supplied with electric starting and light plants, and they appear in their distinctive finish of ivory white and tan. Two-speed axle, which is a decided innovation, has incorporated in its gear a two-speed system. These are a medium direct-drive of 3.5 to 1 and a high direct drive of 2 to 1. This combined with the three-speed gearset gives six speeds forward and two reverse. It is claimed by the makers that a great saving in fuel consumption is retained through the medium of the two-speed action, 50 per cent. more mileage being obtained per gallon of gasoline as compared with medium direct drive. Another point claimed for the two-speed axle is its aid to silent operation, the high-gear ratio eliminating noises caused by low-geared motors on level road.

Bergdoll—Greater Wheelbase

Bergdoll cars for the new season, the 40 Fairmount models in particular, have been greatly refined in appearance and enlarged by the use of a longer frame, the wheelbase, formerly 115 inches being in the new models 121 inches in length. The most notable change, however, is in the adoption of U. S. L. electric starting and lighting system. Motors are of the four-cylinder block type, with cylinders 4 by 5.9375 and 4 by 4 respectively. Equipment is complete on each model, in top, windshield, demountable rims, etc.

Buick—Has Five Models

The 1913 Buick cars are in five models, known as the 24, 25, 30, 31 and 40. Models 24 and 25 are hung on the same chassis, 24 being a roadster and the 25 a touring car. The four-cylinder motor is of the valve-in-the-head type with semi-steel cylinders cast in pairs giving a three-bearing crankshaft. Cooling circulation is maintained by gear-driven centrifugal pump bolted to the crankcase and through brass water manifolds and a vertical-tube radiator. The clutch is an aluminum cone, faced with leather, and transmits the power to a three-speed selected gearset running on annular ball bearings. The steering gear is the semi-irreversible split nut-and-worm type. Models 30 and 31 have the same chassis; in this case the 30 is a runabout and 31 a touring car. The motor in this case is a unit with the clutch and gearset. It has four cylinders of the valve-in-the-head type, and a bore-stroke ratio of 1. The cylinders are of semi-steel analysis and the crankshaft is carried on three bronze-backed babbit-lined bearings. The clutch is an aluminum cone faced with leather with spring beneath to prevent harsh action. A three-speed sliding gearset is used and is carried on annular ball bearings. Model 40 Buick has a block motor without valve cages, the valves being carried in the head. Three-bearing crankshaft is also used in this motor. In general design this model is similar to the other Buicks, having the leather-faced cone clutch, three-speed gearset, direct drive to bevel gear in the differential, semi-irreversible split nut and worm steering gear, and right drive and control.

Cadillac—One Chassis, Seven Bodies

One Cadillac chassis upon which seven styles of body may be mounted is on the market for 1913 and, although to external appearance the motor presents the general Cadillac features of design, a number of mechanical changes having been made. The stroke has been increased from 4.5 to 5.75 inches, while the bore remains at 4.5 inches. The horsepower has been increased from 18 to 25 per cent. owing to this change, althongh according to the S. A. E. rating it still remains at 32.4. The makers claim the motor develops from 40 to 50 horsepower on the block. As would be expected from an increase in the cylinder dimensions a number of increases in other dimensions throughout the motor may be expected. This is so. The principal points of increase has been in the camshaft, which has now a diameter of 1.1875 inches in place of .75 inch. It is mounted on three bearings now instead of on five, the greater diameter giving the greatest stiffness and thereby allowing of a larger stand between bearings. Otber points of increase are the crankshaft wristpin and connecting-rod bearings. Silent chain replaces the spur gears in driving the camshaft. Lubrication remains the same, the splash system being used. Separate copper waterjackets are used on the cylinders, while the radiator consists of 147 seamless copper tubes which pass vertically through 135 horizontal copper plates. The Delco electrical system is used. Improvements have been made in the latter, however, in the shape of minor refinements, such as concealed wiring, fuses and a Yale lock on the ignition switch. The wheelbase has been increased to 120 inches in place of 116 inches. A cowl is used on all the new open bodies in place of the dash, and all the open bodies are made of sheet steel; closed bodies are aluminum.

Cartercar—Bigger Motor

Model 5 Cartercar has been put on the market for 1913. Four different types of body are mounted on this chassis and all have a new electric starting and lighting system, and the following improvements: The motor has been made higher and narrower and now has a bore of 4.125 inches and a stroke of 4.75 inches. The valve action is on the left side and three-point suspension is used as before. The gasoline tank is in a new position. This year finds it placed beneath the cowl of the dash rendering it possible to lower the body on the frame and to raise the carbureter much higher. The tank is filled from in front of the windshield and is fitted with a gauge which is visible from the driver's seat. Lubrication system has been modified, the oil reservoir being enlarged, and a better shape given the crankcase. A new type of plunger pump is used to circulate the oil. The friction on the drive members of the friction gear can be altered by removing the front footboard, loosening a nut and screwing down a bolt. A one-piece windshield has been placed on the touring and roadster cars. Top straps are fastened to the dash and not to the frame at the lamp brackets as heretofore. Seat springs are built higher in front than in rear to prevent passengers from being thrown forward. Springs are of the double-deck type. Full equipment is fitted on all cars.

Case—Adds New Four

Two models of Case will be on the market for 1913, the model 30, which is entirely new, and the model 40, which was on the market last year, but which has been improved in many respects. The model 30 has a four-cylinder 4.125 by 5.25-inch motor, Westinghouse electric lighter and starter, Remy magneto, Rayfield carbureter, floating rear axle, demountable rims, fore-door ventilators, and a 115-inch wheelbase. The running boards on this

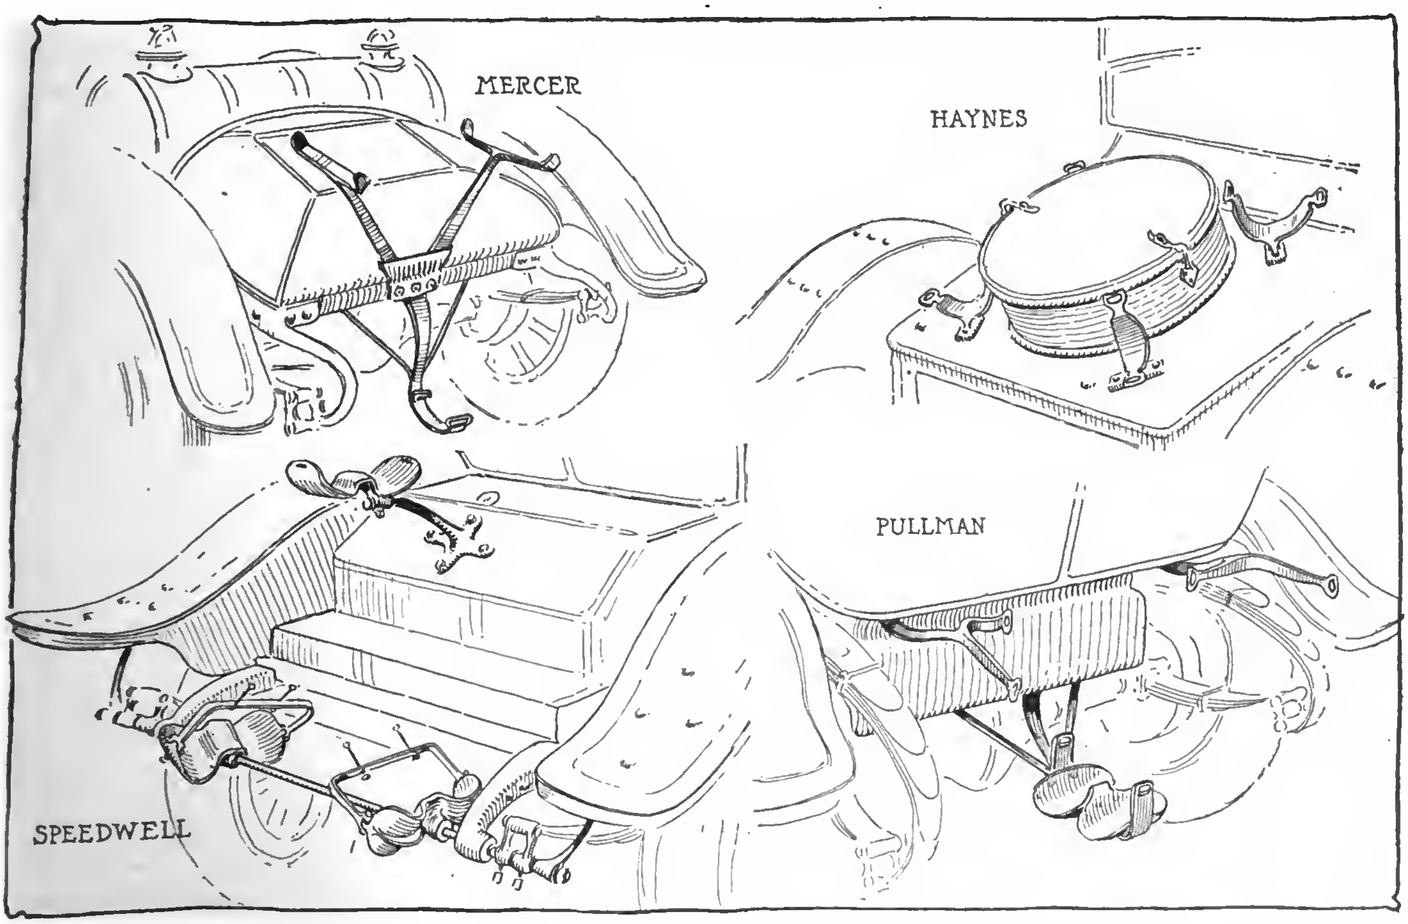

Fig. 3—Great attention being given to making rear tire carriers rigid

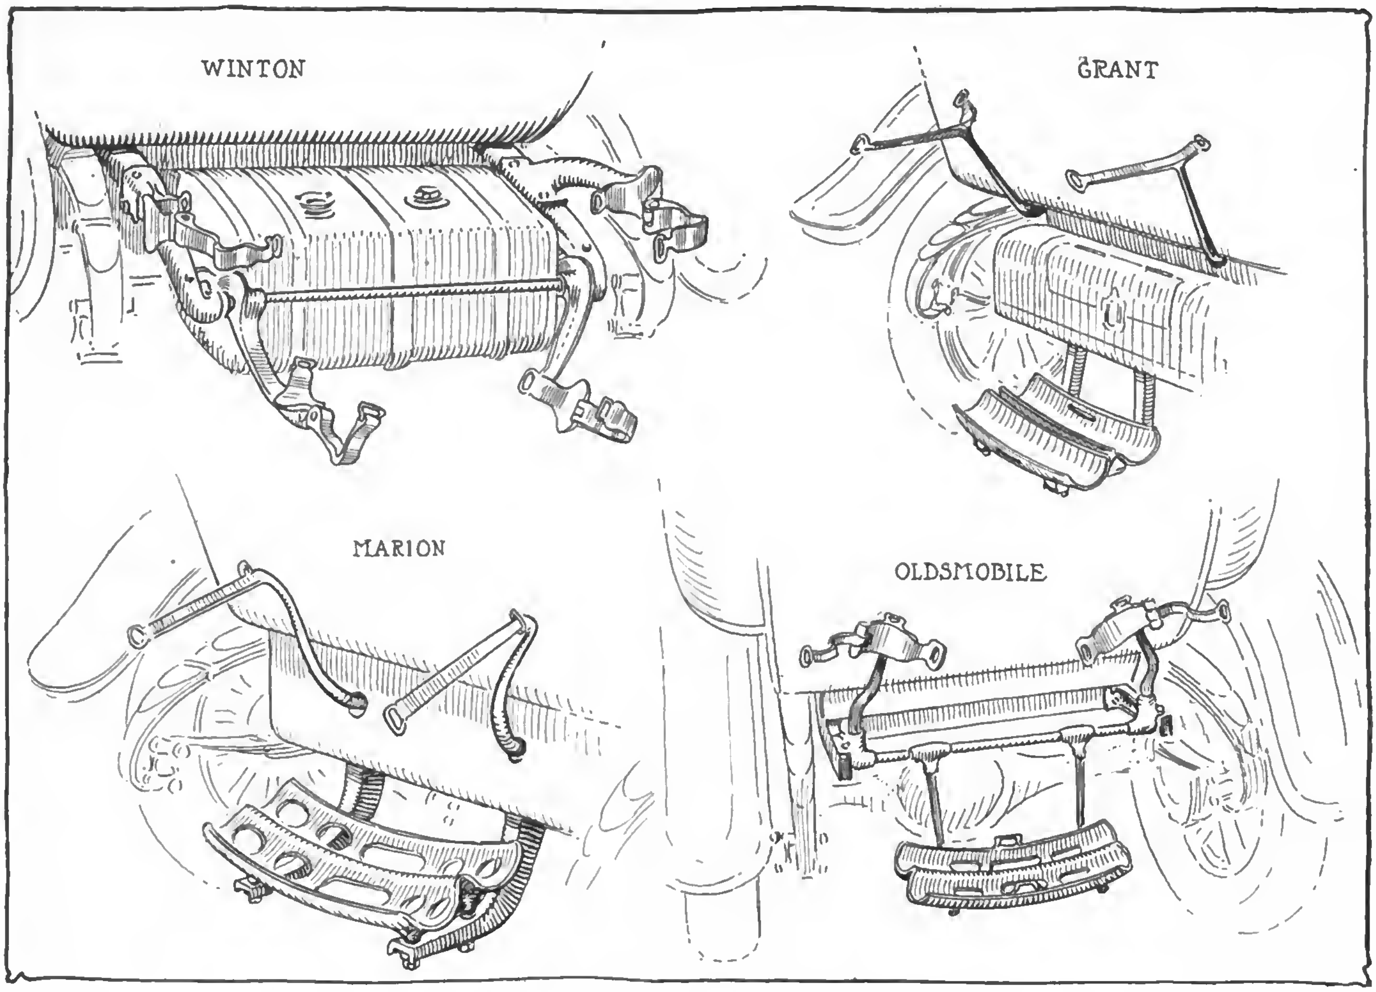

Fig. 4—Rear tire carriers often made integrally with chassis frame

model are absolutely clean, the extra 34 by 4-inch tires being carried on brackets in the rear. The design of this car is similar to the 40 in its improved state. The same 4.5 by 5.25-inch motor is used as last year, but the wheelbase has been increased to 124 inches, whereas last year it was 120 inches. The wheels are now 37 by 4.5 inches instead of 36 by 4. The rear springs are underslung, a Westinghouse electric starting system has been added, Remy dual takes the place of Remy single ignition, pressure gasoline system is used in place of gravity, and the equipment has been rendered more complete.

Cameron—Makes Four Models

Air cooling continues to be the feature of Cameron cars. Four models are produced, as last year, styled 28, 29-A, 30 and 32. These designations refer to body styles, models 28 and 29-A being a two-passenger runabout and five-passenger touring car, respectively, mounted on the same four-cylinder chassis. Models 30 and 32 are corresponding bodies on the six-cylinder chassis. Model 28 has a wheelbase of 104 inches; model 29-A, 110 inches; model 30, 114 inches, and model 32, 130. The valve-in-the-head, individually-cast, air-cooled motor, the cone clutch, the full elliptic springs in the rear, the Cameron transverse, direct-drive rear axle gearset and floating axle are all retained, as formerly.

Chalmers—Adds a Six

Three models of Chalmers cars are now on the market for 1913. Two of these are fours and the other is a six. This is the same as last season and the changes made have been all of a minor nature, reduction in price being the most important. The cylinder dimensions of the three models are the same as last year, the bores of the three models being 4.25 inches for the four and the six, while the strokes are 5.25 for the six and larger four, and 4.5 inches on the smaller four. Monobloc castings are used in the four-cylinder models, while the six uses two groups of three. A slight change in the air-starting system consists in the installation of Kellogg pumps to take the place of the cylinder check valves used to take the pressure from the cylinders and convey it to the storage tank. The transmission service brake has been omitted in the smaller four this season and both brakes placed upon the rear wheels. More luxurious upholstery, sheet steel bodies, long cowl dashes and seats to which a pitch of 2 inches is given form some of the other refinements worth of comment. The Gray & Davis lighting system is used in these cars which are fully equipped.

Chevrolet—Has New Six

The Chevrolet 40 of 1913 is a six-cylinder car with motor composed of two block castings containing three cylinders each. The measurement of the cylinders is 3.5625 by 5 inches. It is of the T-head type and the valves are 2.25 inches in diameter. The pistons are convex. Connecting-rods of I-beam forging equipped with die-cast babbitt bearings. The crankshaft is a drop forging with counterweights forged integrally with the shaft. The four main bearings are of babbitt metal, as are also those of the camshaft. Lubrication is by automatic and mechanical oiling system. The carbureter is heated from the exhaust and is automatic in its action. Dual magnetos are used in ignition. The clutch is leather-faced cone type with adjustable compensating springs. The gearset provides for three selective speeds forward and reverse. Cooling is by centrifugal pump and belt driven fan. The front axle is a drooped forged I-beam and the rear is of the full floating type. Sixteen-inch drums are used for the brakes. Three-quarter elliptic springs are used in the rear with semi-elliptics in front. Steering is by worm and gear. The car has an electric generator for lighting and is

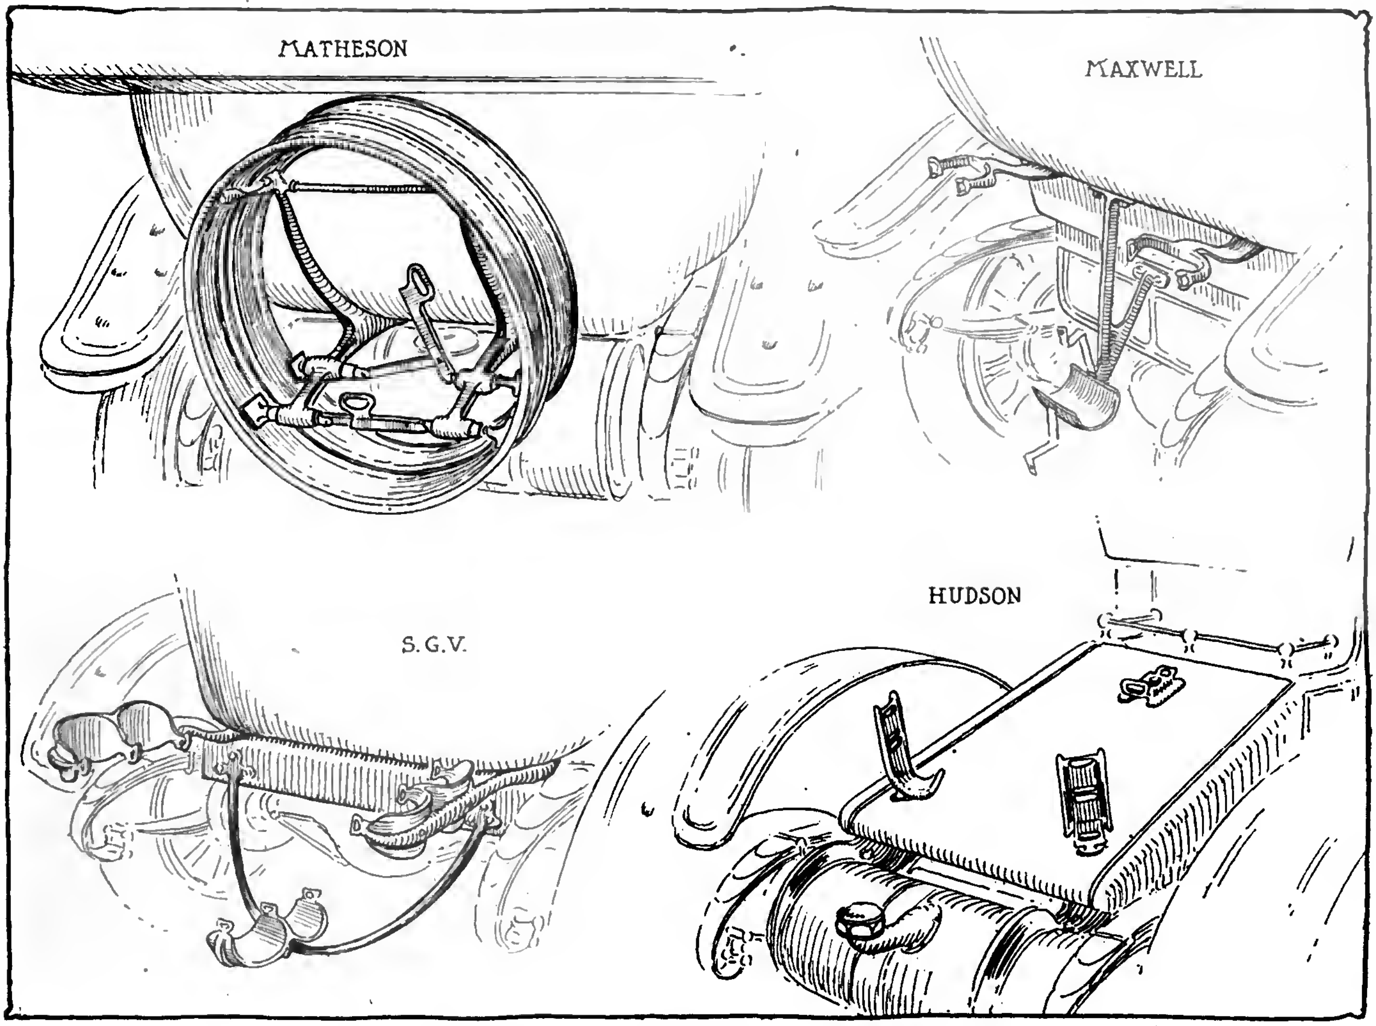

Fig. 5—Accessibility and sightliness favor rear carriers

equipped with a pneumatic starter. Wheelbase is 120 inches with standard tread.

Correja—Puts Out a Six

A six-cylinder Correja has been added to the line for 1913. On this model the cylinders are cast in pairs, are of the T-head type, and have a bore of 4.5 inches and a stroke of 5 inches. The car is rated at from 55 to 60 horsepower and ignition is taken care of by a Simms high tension magneto with a set spark. Carbureter is the new model O Schebler with concentric jets. Lubrication is taken care of by gear-driven pumps which deliver the oil through a hollow crankshaft; the oil being carried in the lower part of the crankcase. A cone clutch with flat springs under the leather casing is used and delivers the power to a three-speed selective gearset located on the rear axle. One universal joint is used in the propeller shaft, this being of the double type and located at the forward end. It is inclosed in a torsion tube. The rear axle is floating and has a removable housing cover through which the differential gears may be examined and adjustments made. Three-quarter elliptic springs, 44 inches in length are used in the rear and semi-elliptic springs in the front. The brakes are mounted on the rear wheels operating on pressed steel drums, and equalized by differential levers.

Cole—Adopts a Six

For the 1913 season the series 8 Cole is now on the market. A new six-cylinder, 55-horsepower car is the greatest innovation for this season. It has a bore of 4 1-8 inches and a stroke of 4.75 inches, with a rated horsepower of 55. The other two models, known as the 40 and 50, have four cylinders. The smaller has a bore of 4.125 inches and a stroke of 4.75 inches. while the 50 has a bore of 4.5 inches and the stroke 5.25 inches. The motors are all of Northway manufacture and are of unit construction, the gearset and clutch housing forming the rear portion of the structure, and so arranged as to give the rear support in a three-point suspension. Some of the other features of Cole construction for 1913 are the gas pressure feed with small plunger pump driven off camshaft, leather disk drive for generator, ventilating attachment on windshield, air control on steering column, 4-inch longer rear and 2-inch longer front springs, gasoline gauge on tank having 21-gallon capacity and rear tire holders. Cylinders are of L-head type and are mounted on an angle of 2 1-2 degrees to the vertical, producing a straight-line drive when the car is loaded. There are no radical features of design about the motor, although the external shafting has been so arranged as to incorporate the Delco starting and lighting system. The motor generator is located on the right side of the motor and is driven through one of the gears of the timing set. The Cole automobile is one of those upon which no starting crank is carried, the latter being kept in the tool box for use in case of emergency. Rakish and gracefuly body designs distinguish the Cole line for 1913. Not the least noticeable feature is the polished cowl board carrying the speedometer, sight-feed, pressure gauge, switch and starter.

Crane—Has New Six

This is a new car which has just been placed on the market. It is made in one chassis embodying a six-cylinder motor having a bore of 4.375 inches and stroke of 6.25 inches. A direct force feed system of lubrication is used, the oil being delivered to the main bearings under 3-pound pressure. A single disk clutch, four-speed gearset, transmission brake, floating axle,

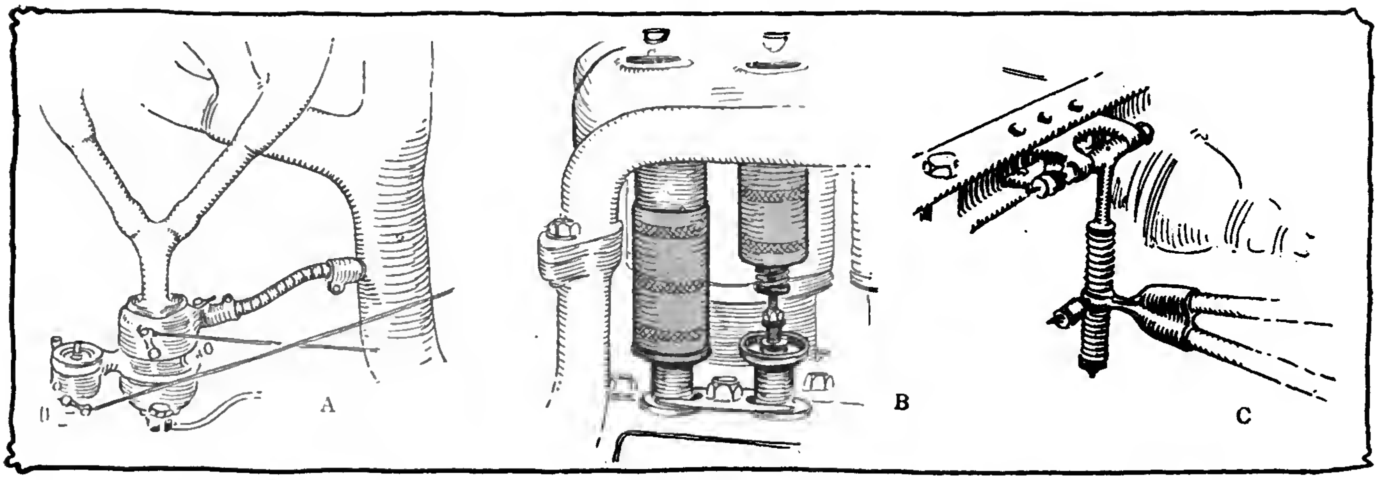

Fig. 6—A, Buick hot-air carbureter jacket; B, Cadillac valve action covers; C, Cadillac torque connection

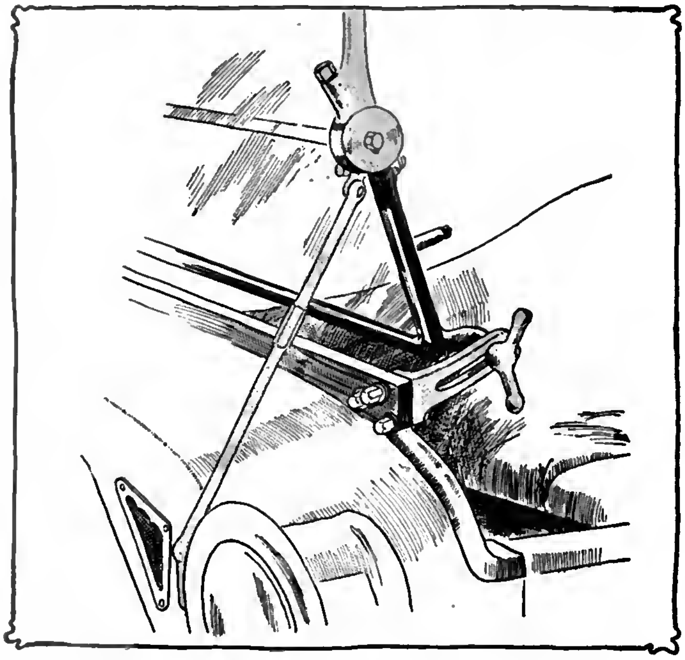

Fig. 7—Cole ventilating shield attachment

chrome nickel steel frame are among the prominent features of the car.

Simplex—Makes Three Chassis

As before, the Simplex Automobile Company will produce three chassis with bodies to order. Two of the chassis offered last year are continued with no mechanical alterations whatever, although a generator electric lighting system has been installed in all models. The 90-horsepower model will be continued in small quantities for those who demand great power, and in its place a chassis practically identical with Louis Disbrow's Simplex Zip has been installed in the line. This model has flat springs and sets much closer to the ground than former Simplex productions. The cylinders, four in number, are 5 3-4 inches square, and, while this engine is allowed 53 horsepower by the S. A. E. rating, it is said to develop 90 on the brake. This model is chain-drive, and will be furnished either as a chassis or in a racy two-passenger roadster. It will be remembered that the other models are a 38-horsepower, shaft-driven chassis with a 4 7-8 by 6 1-2-inch motor and two wheelbases, 127 and 137 inches, respectively; and a 50-horsepower, chain- or shaft-driven chassis, with four cylinders 5 3-4 square. This chassis has wheelbases 129 and 139 inches, respectively. While the bore and stroke of this motor are the same as the new model, the latter motor differs in design, notably in the size of the valves, which are the same as used in the 90-horsepower model, thus deriving its additional power. The new model is termed the 75. The Simplex body policy will be continued. This policy is to furnish bodies partially finished on each chassis, which are carried out in detail to suit the individual preferences of the purchaser, at his order. An especial body production is a semi-steam-line coach limousine with a curved roof and sloping hood.

Crow—Adds a Six

Five chassis and nine body models constitute the 1913 Crow line. The horsepower ratings of these models are 25, 33, 35, 45 and 50, the last mentioned is an entirely new design and is known as the C-6. It has six cylinders and is equipped with both roadster and touring bodies. The smaller two models have four cylinders and are monobloc castings. The exhaust and water manifolds are cast integrally with the cylinders in the case of these two. The four-45 as well as the new six-cylinder models are all of the L-head type with the cylinders cast in pairs. Cooling in all models is accomplished by the thermo-syphon system, and the radiators are mounted on trunnions. Ignition is by a Briggs dual system. Some of the new features included for this season are the gasoline gauge for the gas tank placed under the left front cushion, the arrangement for carrying dry batteries by means of a wooden drawer, and a space for the storage of tools and a compartment to the left of the tank. Baffle plates are placed in the gasoline tank to prevent the fuel from splashing back and forth. The wheelbase on the new six-cylinder car is 137 inches and it is equipped with 37 by 4.5 wheels with demountable rims all around. A feature on the Crow car which is interesting in view of the large number of automobile thefts recently, is the lock on the control set. A small boss is cast on the H-plate and on the gearshift lever. These bosses are pierced by a 3-8-inch hole, making it possible to fit a padlock to the gearset, holding it in neutral position and rendering it impossible for anyone to engage the gears unless provided with a key. The center control was used on the 1912 cars and the cane handle gearshift lever is also used, the ball on the top of the lever being 1.5 inches in diameter. The distance through which the gearshift lever has to be moved is very short.

Cunningham—Makes One Model

One model, a four-cylinder type, is placed on the market for the 1913 season by the Cunningham company. The bore and stroke are 4.75 x 5.75 inches. The cylinders are of the valve-in-the-head type and are offset from the crankshaft. A three-speed gearset, cone clutch with cork inserts, floating axle and screw-and-nut steering gear are other features. An electric starter and generator are regular equipment.

Cutting—Adopts Unit Plant

Two up-to-date styles of body, a roadster and touring car, are now fitted to the single Cutting chassis on the market for 1913. Although the basic principles of construction are the same this season as last, some important refinements have been made. Among these are the adoption of the unit power plant with three-point suspension. Other prominent features are increased wheelbase, demountable rims, 36-inch wheel on all models, electric side and tail lights, gas headlights, roomy metal bodies and acetylene starter. Roadster and touring car bodies are interchangeable. The four cylinders are cast in one block and have a bore of 4 inches and a stroke of 5 inches. Lubrication is by force-feed through a hollow crankshaft direct to the main and connecting-rod bearings. The connecting-rods do not dip into the oil in this system of lubrication. The force feed given by the pump, which is driven off the crankshaft, is relied upon to furnish a sufficient supply of oil for all the bearings throughout the motor. Timing gears receive their oil from the crankshaft gear which runs in a pocket that is always kept full of lubricant. The clutch is of the dry-plate disk type, the disks being seven in number and composed of cast iron. The oil pump is of the gear type. A three-speed gearset is used, and the axle is floating. Full electric lighting and starting are furnished at extra cost.

Davis—Adds Larger Model

Continuing Model 40 in series A, the Davis Motor Car Company announces a new model, larger than the first. Model 50 A is built along very similar lines to the 40 A, but employs a 50-horsepower Continental motor. The older model shows several improvements over the original design. The wheelbase has been lengthened from 112 inches to 118 inches, and the equipment amplified by the addition of a Gray & Davis lighting system, with a Disco starter, with option of the Gray & Davis starter. The new 50A uses a Continental 4.5 by 5.5-inch motor with cylinders cast en bloc. Otherwise it is identical with the smaller car. A Stromberg is used. Bodies include five-passenger and four passenger touring bodies and a two-passenger roadster with a streamline rear deck. Refinements in the bodies have been made throughout the line of touring cars.

Detroiter—Better Finish

No changes have been made in the Detroiter car for this season except minor refinements and betterments in finish. The motor is of the block type, in this car, with the intake manifold passing through the casting between the center cylinder. The bore of this motor is 3 3-8 inches and the stroke 4 3-4 inches. Three-point suspension, inclosed valves, multiple disk clutch, thermo-syphon cooling and spiral timing gears are among the other features. Left drive and center control are also incorporated, together with the long cowl and straight-line body of accepted design.

Dorris—Refined Motor

Fundamental design has undergone no change in the Dorris cars for 1913, unit construction in the 4.375 x 5-inch four-cylinder valve-in-the-head power plant still being retained. The motor changes are in a better valve action, a three-way sight feed on the oiling system and an additional gear on the timing set to take care of the Apple dynamo-motor for electric lighting and starting. The clutch, gearset and rear axles disclose no change. Six inches have been added to the wheelbase, making it now 121 inches, and the flush-sided body with the cowl dash has been adopted.

Edwards—Uses Knight Motor

One of the newest American cars is the Edwards-Knight, which was announced less than a month ago and which was described in detail in these columns, issue of December 12. In addition to using the Knight two-sleeve motor the car has numerous other constructions, many of which are incorporated in the latest European models. Among these details are detachable wire wheels with Q-D rims, with wood wheels optional; and Lanchester type of rear spring in which the weight of the spring is carried on the frame and so reduces the dead weight on the axle. The motor has a new non-splash forced-feed system of oiling in which the throttle controls the oil pressure, which ranges from 2 pounds with practically closed throttle to 20 pounds with the throttle open. It is one of the few cars to use forged connecting-rods of round section with the insides drilled out to reduce weight, leaving a wall thickness of .125 inch. The U. S. electric flywheel starter is fitted, and the motor carries a Simms magneto and S. U. carbureter. In the transmission system the multiple dry-disk clutch and gearset are in the gearbox in separate compartments. The clutch is in the front part. The rear axle is worm-

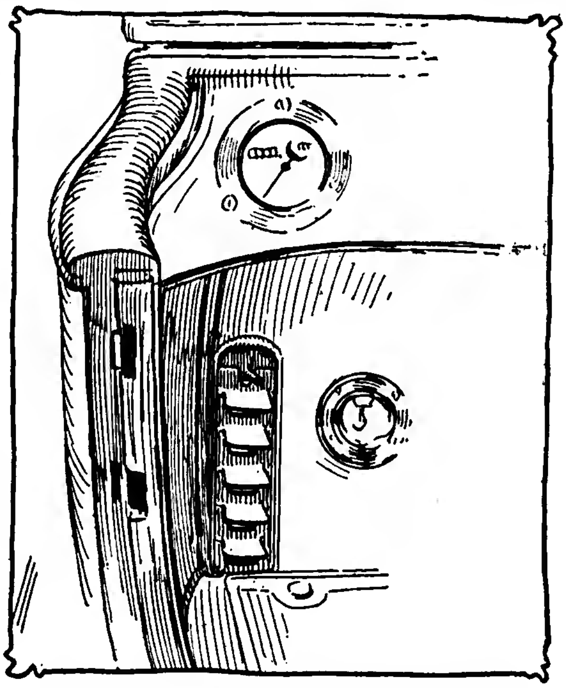

Fig. 8—Ventilating device on Chalmers dash

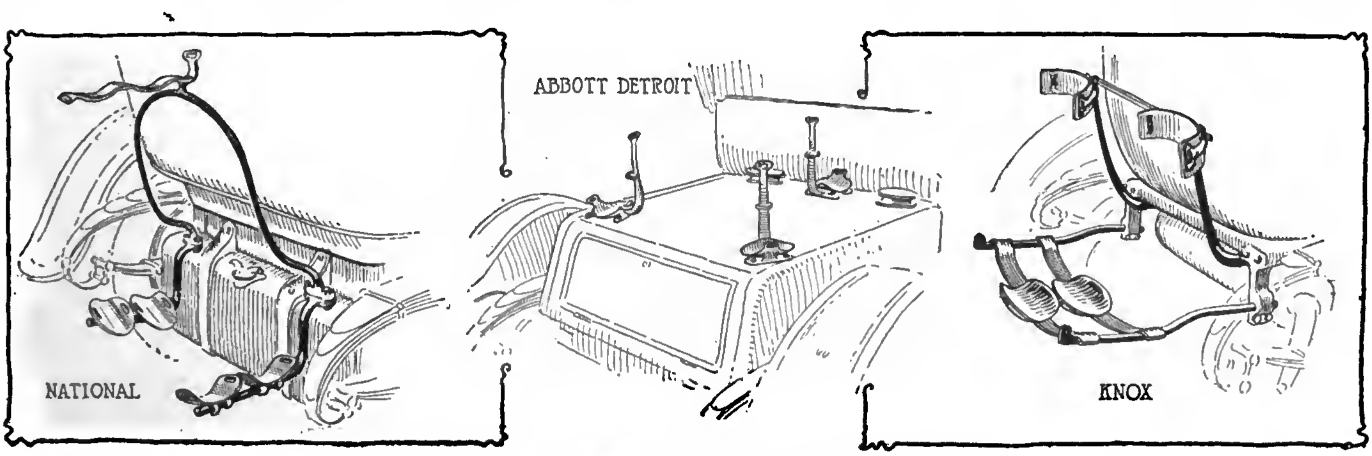

Fig. 9—Three distinct types of rear tire carriers which give rigidity

driven with the worm underneath, yet affording an axle clearance of 9.25 inches. The axle is a Timken construction fitted with worm and worm wheel made by David Brown, of England. It is a straight type worm carried on Timken rollers, which bearings also take up end thrust. The car has straight-line drive in that both motor and gearbox are mounted to decline rearward at an angle of 4 deg., so that with the car loaded the crankshaft, gearset shaft, propeller shaft and worm shaft align. The propeller shaft has two universal joints, two radius rods take the driving action of the rear axle, and in addition there is a torque tube. The radius rods, torque tube and propeller shaft are so designed that there is not any slipping of the universal joints and by having the same angle of drive through the front universal as through the rear one, the retardation and acceleration which occurs twice in each revolution of the joint is neutralized. Various body types are mounted on the same 120-inch chassis. It has left-hand steering and center control with a double-dropped frame.

Empire—Uses Unit Plant

Larger, more powerful and more complete in every particular the Empire car appears for 1913 in Model 25, a big brother to the former 20. This model was announced early in June. The design embodies the features of an inclosed unit power plant, with cylinders cast in pairs, 3.5 by 4.5 inches bore and stroke. The valves are all on the left side, their mechanisms inclosed in cylindrical individual housings. The crankshaft is supported on three bearings and lubrication is by the circulating-splash system. Fixed adjustment is used in the Eisemann high-tension single ignition system. Thermo-syphon cooling is employed. The car is steered from the right side, and the control lever is in the center. A five-passenger touring body with fore-doors is fitted.

Enger—Encloses Valve Action

Models F, J and E of Enger cars are continued, while a new model P has been announced for the present season. The new model differs little mechanically from models F, J and E, using the same 4.5 by 5.25-inch motor with inclosed valves arranged on the left side. An especial feature is the means of closing the valve chambers. The cylinders are cast in pairs, and the valve chamber of each pair is covered by a single plate which carries the spark-plugs and pet-cocks, and which, when removed, permits ready accessibility to the valves. Multiple-disk clutches, three-speed selective gearsets and floating axles are used on all models. Model P is fitted regularly with the North East electric lighting and starting system, all models being equipped with a top and envelope, windshield, speedometer, horn and tools. All models are listed with full equipment.

Fiat—Adds Large Four

The American as well as the foreign Fiat is built in three chassis models, the parts in the American factory being made from the foreign drawings and superintended by foreign engineers so that the domestic and foreign models are duplicates in respect to design, material and workmanship. To the four- and six-cylinder models of last year a large four has been added which coincides in nearly every respect with its two predecessors. These chassis are characterized by block cylinder castings with a transverse front end shaft to drive the magneto and water pump, four-speed gearbox and combined pressed steel rear axle and torque tube, in which two stampings constitute the entire housing, these two being specially light, their total weight in the rough being but 80 pounds. The motor has a forced-feed non-splash oiling system, supplied from an exceedingly compact gear pump mounted on the rear end of the camshaft and delivering its oil through a large diameter conduit, incorporated within the crankcase when cast, from which conduit the three crankshaft bearings are supplied. The crankshaft throws and crankpins are drilled and the connecting-rods carry copper tubes to convey the oil to the wristpins. The exceedingly compact four-speed gearset is a Fiat feature, the total length between bearings being but 10 inches. The new tour has a compression release fitted. All models carry electric lights, but engine starters are not listed. For the first time all Fiat models have the full-dinner-pail equipment which includes everything that the owner requires. Fiat chassis are internationally renowned for their clean-cut appearance; every detail has been designed for its duty and place and looks the part. An example is carrying the magneto control through the crankcase from front to rear thereby eliminating unseemly connections and more fool-proof control. Another example is the clean-cut block casting, with enclosed valve springs and abbreviated manifolds and water connections.

Firestone-Columbus—Electric Starter

Three different chassis are made by the Firestone-Columbus Company. One is a six and the others are four-cylinder models. The six-cylinder motor is cast in groups of three and is of the L-head type with enclosed valve mechanism. Double ignition with two independent sets of spark plugs is used on this model. The wheelbase of this car is 130 inches. The bore of the motor is 4.5 inches and the stroke 5.5 inches. The largest four-cylinder has a bore of 4.5 inches and a stroke of 5.5 inches. Double ignition is used on this also, while on the smaller four dual ignition is used. All models have electric lighting and starting systems, three-speed gearsets and demountable rims.

Flanders—Nothing But Sixes

The Flanders company is another of the increasing number who make nothing but six-cylinder cars. The two chassis put out by this concern are known as the 50-Six and the 40-Six. Both of these cars are newly on the market. The 40-Six has an en bloc motor with a bore of 3.625 inches and a stroke of 4.5 inches. The oil system has a 2.5 gallon capacity, and is of the combination force and splash type actuated by a gear pump driven from the camshaft. The Gray & Davis starting and lighting system has been fitted to this motor as well as to the larger 50-Six. The motor of the latter is also of the block type, has a bore of 4 inches and stroke of 4.75 inches. It is lubricated by the same system as the smaller car and is of the same general design throughout. The control on both models has been arranged so that the gearset lever does not operate with an H-plate, but by a rocking motion. Both the clutch and brake pedals are adjustable. The gearsets have three speeds forward and reverse and are geared 3.5 to 1 on high on the 40-Six and 3.75 to 1 on the 50-Six. A trouble lamp on a longcord, cigar lighter, rear tire irons and hub cap wrench are part of the equipment of both models.

Ford—Heavier Axle

The only important change in the Ford cars for the coming season is in the price, which has been cut since the first of October, 1912. A two-passenger roadster, five-passenger touring car and a six-passenger town car make up the Ford pleasure line. Improvements which have been made in the Ford line consist largely of changes which tend to better the appearance and to increase the comfort of the passenger. The bodies are dropped 2 inches lower and the roadster has been redesigned so that it is now possible to convert the turtle back into a seat for a third passenger. The axle housing has been made heavier.

Franklin—Electric Starting

Electric starting and lighting on the new Franklin series 3, six-cylinder cars is the biggest change presented in this line, which is now listed in series instead of the yearly models. The Entz system which has been installed consists of three parts: an electric motor generator, storage battery and a three-point double-throw switch. The system operates at 18 volts and has the motor generator connected permanently to the crankshaft by a silent-chain drive. The motor-generator is so constructed that it will turn over the motor at low speed, but as soon as the car has picked up speed it will act as a generator and start charging the battery. The winding employed on this starting system is such that it is a natural function of the motor-generator for it to become a generator after the speed of rotation has mounted to a car speed of 12 miles. Below this speed it performs the functions of a motor. This does away with automatic devices. Another addition to the Franklin line is the little six two-passenger victoria phaeton which has an auxiliary seat in the rear for two, the latter folding into a deck when not in use. Otherwise the Franklin series 3 is the same as series 2.

Garford—Makes a Six

Garford production in the pleasure car line will be confined to one entirely new six-cylinder model in 1913. The car has a construction of 1912 in the essential elements. The car bas a wheelbase of 128 inches. Its overall length is 178 inches. The cylinders are of L-head type, the bore being 3.75 inches by 6-inch stroke. Under the S. A. E. formula the rating is 33.75 horsepower, but in the catalogue the motor is called 60-horsepower. The cylinders are cast en bloc with valves on the right side fully enclosed. The crankshaft is a steel forging with four bearings of babbitt-lined bronze. Lubrication is by gear-driven pump with the oiler in the crankcase. Copper tubes lead to the main bearings and oil leads through the crankshaft to connecting-rod bearing and wristpins provide for lubrication of those parts. In addition there is a splash system. High tension ignition with waterproof magneto and battery is installed. The cooling system consists of a honeycomb radiator and fan as last year. A cone-faced clutch with cork inserts, having a face 2.125 inches, is slightly changed from last year. Four speed, selective transmission gives direct on third and final drive is by bevel gear and pinion to floating rear axle; Garford worm and gear steering; Krupp steel springs, three-quarter elliptic in the rear; kick-up pressed steel frame and an electric starter, tbe motor generator of which takes the place of the flywheel, are some of the details of the new car.

Glide—Adds New Four

An entirely new four-cylinder Glide has been put on the market for the 1913 season. This car, which is known as the 36-42, is being built along similar lines to its predecessor of last year. The improvements incorporated are a 4-inch longer wheelbase, making 118 inches, a larger motor having a bore of 4 1-8 and a stroke of 5 1-4 inches, and larger and heavier parts throughout to take care of the additional weight due to the longer wheelbase and more powerful motor action. The four cylinders are a monobloc casting tested under hydraulic pressure for casting flaws. The valves are all located on the left side of the motor and are covered by cast-iron removable plates to silence their action. The flywheel housing is a unit with the crankcase and is cast of nickel aluminum alloy. Acetylene starters are fitted on the Glide touring and roadster cars, while the lighting system is the Ward Leonard. A motor-driven tire pump is included in the equipment of these cars.

Great Western—One Chassis

Great Western cars are built for the season of 1913 in four body types upon a single chassis model. This chassis is known as the 40, as it has been for the past few years, but this year the motor is larger, the stroke being 5.5 inches in place of 5 inches, while the bore remains 4.25 inches as formerly. A more radical change of design is the placing of the exhaust valves on the side of the motor in a regular L-type construction in place of in the head of the motor, as they were formerly. In connection with the change in the valve location is a new feature in the use of roller valve lifters acting directly on the cams. The valves themselves are cast iron electrically welded to carbon steel stems. The power plant is the unit type with lubrication by splash. The new Remy dual system with concealed coil is also used. A slight change has been made in the clutch in that the angle of the cone has been flattened so that it will act easier. Other features of the car are the floating axle running on a double roll of New Departure ball bearings with Hyatt rollers for the differential and the worm and full gear type of steering. The wheelbase shows an increase of 4 inches over last year's product; it is now 118 inches.

Grant—Makes a Six

One of the new cars to be first seen on the market for 1913 is the Grant Six. It embodies a T-head 50-horsepower Wisconsin motor, a multiple disk dry-plate Grant-Lees clutch and a gearset having three speeds forward made by the same concern. The motor clutch and gearset when assembled make a complete unit power plant. Timken axles are used, and the body is made of three-ply laminated wood. Marvel carbureter, Esterline generator, Gray & Davis lamps, mohair top, Gemmer steering gear and complete equipment are furnished.

Westcott—New Light Six

In line with the present trend in favor of light, medium-priced sixes, the Westcott Motor Car Company announces a six in addition to its continued four. The four differs little from its predecessors, the chief change in mechanical features being the installation of an electric starting and illumination system. The six-cylinder is one of the many new sixes of this season. An aim has been made in its manufacture to effect simplification of structural features following the same general lines laid out in the four-cylinder cars. The motor is cast en bloc, 4 by 6-inch bore and stroke with valves arranged opposite instead of in an L-head as previously. The car is claimed to develop 67 horsepower and to weigh 3,500 pounds, or to have 1 horsepower to every 52 pounds in weight.

Warren—Adds a Six

Continuing its three four-cylinder models and adding a six-cylinder type, the Warren Motor Company enters the 1913 selling season well equipped to meet the demands of all comers. All three of the fours have different cylinder dimensions, none of which correspond to those of the new six, which has a bore of 4 inches and a stroke of 5 inches. The fours are identical in all but the most minor details with their counterparts for last season. The six adheres to the monobloc cylinder construction, the upper part of the waterjacket being cast open. It is covered by an aluminum plate with which the water outlet is formed integrally. The new motor, like the Warren fours, is of tbe L-head type, valves being located on the left. The crankshaft has three bearings which are anchored to the upper half of the crankcase in the usual way. The support of the engine is at four points on a subframe. Splash lubrication, positive water cooling, double ignition and pressure gasoline feed are features of the six-power plant. It also is fitted with an electric self-starting and lighting system of the Northeast make. The combined motor-generator is mounted on the right side of the engine and connects to the crankshaft by a 1-inch silent chain. It operates either as a motor for starting or a generator for lighting, as the case may be. Control of the car is on the right. The standard body furnished on the new six-cylinder chassis is a metal foredoor type with swelled back. Door latches being inside, the body is flush-sided, while the bottom line is straight and not cut away to follow the frame drops. Nickel trimmings are fitted, as well as all equipment for immediate road work.

Richmond—Larger Cars

Larger cars are being produced by the Wayne Works for 1913 than for 1912. The same 30 and 40-horsepower motors, of 4 by 4.5 and 4.5 by 5, are used. These motors are of four individually cast cylinders. The valves are located in side pockets on the left side, their springs and lifters inclosed in telescopic tubes. The crankshaft is supported on five bearings. The clutch is of the inverted-cone type with a bronze ring thrust, so arranged that it is bathed in grease upon pressure being applied on it, permitting slippage of the clutch with no harmful results. The three-speed gearset is located behind the clutch, to which it is coupled by a

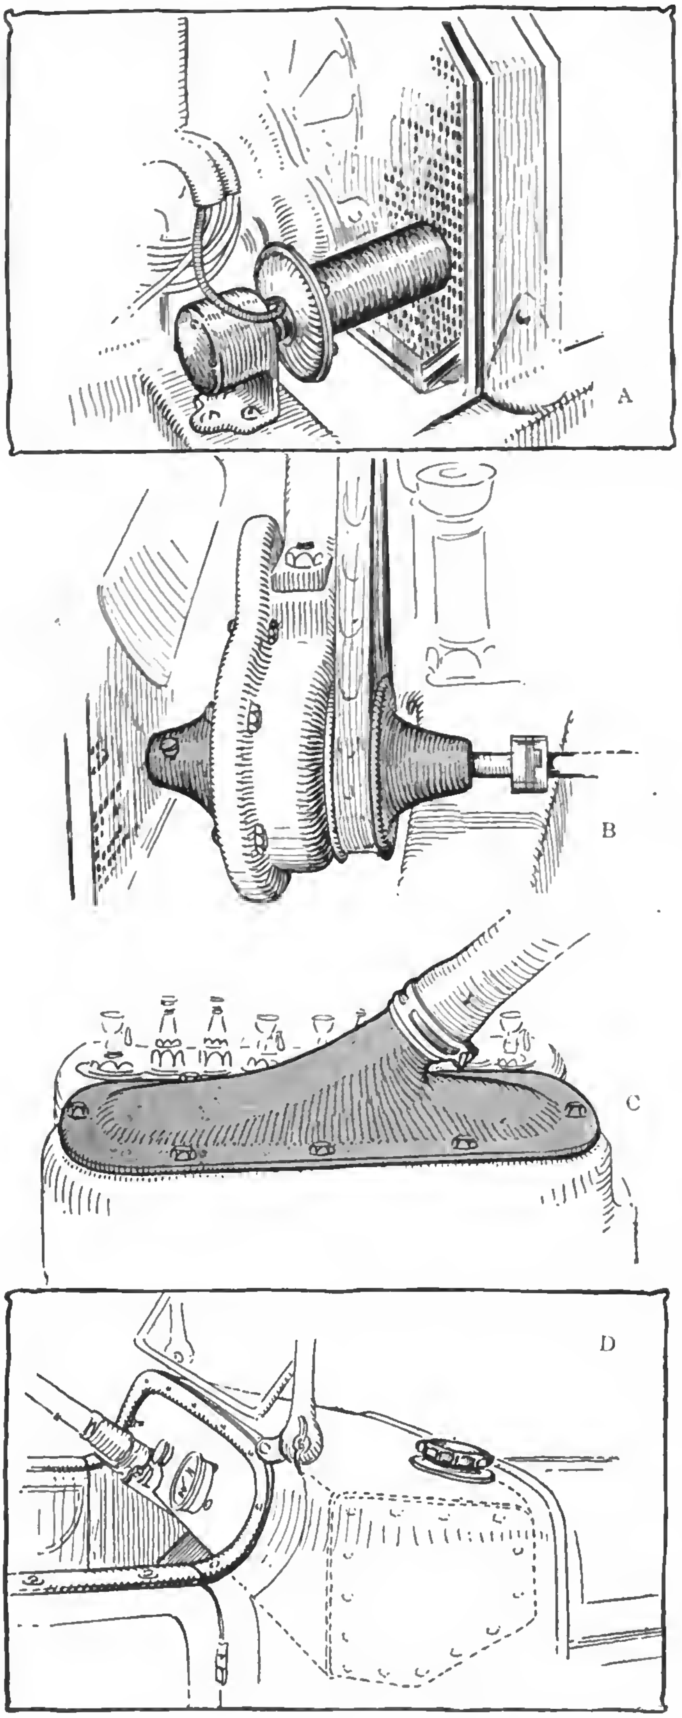

Fig. 10—A, horn on Grant car is attached rigidly to the supporting frame of the motor, the projector being directed through the radiator

B, In order to secure stiffness at the timing gear, the Grant car has a bearing on either side of the gearcase

C, the water manifold and the waterjacket cover are a unit on the Herreshoff car and are removable

D, In order to mount the carbureter as high as possible the gasoline tank is carried under the cowl on the Henderson car

universal joint. Thermo-syphon cooling, formerly supplied on the 40 only, is now provided on both models, and the tubular type of radiator is used. The former dual ignition system has given place to single magneto ignition. A change to Schebler carbureters has been made, and the wheelbase and tire sizes on both models enlarged. Model O, formerly model N, has a wheelbase increased from 106 to 112, and tires from 32 by 3.5 to 34 by 3.5 inches. Model P, formerly model M, has a wheelbase of 120 instead of 112, and tires 36 by 4 instead of 34 by 4. Springs have likewise increased slightly in length. Model P, the 40-horsepower model, is equipped with electric lights, supplied by a dynamo and storage battery. Model O is fitted with an improved foredoor touring car and a Bumblebee roadster. Model P carries a touring car only.

Havers—Only Sixes

No four-cylinder models are included in the Havers line for 1913. Continuing its former six and adding another and larger chassis, the Havers company enters the 1913 season with two sixes. The smaller model is known as the Six-44 and the larger as the Six-55. The former has a bore of 3.75 inches and a stroke of 5 inches, while the latter has a bore of 4 inches and a stroke of 5 inches. On both models the cylinders are cast in pairs and are of L-head design with the valve springs and stems inclosed by aluminum cover plates. Four bearing camshafts, spiral timing gears, combined force and splash-feed oil, thermo-syphon cooling, Northeast starter and lighting, Bosch dual ignition, three-speed gearsets, and floating axles are features of both chassis. Right drive and control are used in the Havers models, which are put up in touring and roadster bodies. The Knickerbocker speedster is worthy of comment in that it is a new effort for the Havers company which believes there is a demand for a machine of raceabout type built along low lines.

Haynes—Adopts Left Drive

A brand new car, model 24, with left drive and left control, distinguishes the Haynes line. The first starting system used by the Haynes company will be on this year's car. It has been designed by the Haynes engineering staff and is of the electric type geared to the flywheel. The alterations which have been made in the model 22, which is a continuation of the model 21, are very slight, the principle one being an alteration of the suspension design. Models 24 and 22 are L-head and T-head respectively, the bore and stroke of the former are 4.25 and 5.5 inches. The oiling system has been changed slightly in this year's models, the pump now being located at the top and outside of the crankcase instead of within it at the bottom. The modification of the spring suspension consists in the attachment of the spring hanger bracket to the end of the frame. The three lowest spring leaves in the upper set have been continued back of the clip for a distance of 3 1-2 inches to act as a stop by striking on the rubber bumper located at the center of the lower half of the spring. In model 22 the frame end is dropped 2 inches lower than in the model 21. The motor has four cylinders cast in pairs, with a bore of 4.5 inches and a stroke of 5.5 inches. The waterjackets are removable at their upper extremity. An Eisemann dual-ignition system is used with a storage battery for starting. The balance of the electric equipment includes the Haynes electric starting and lighting system. The starting system is operated in the seat of the car by first placing the switch on the battery side and then placing a right foot on the brake pedal. With the heel of the left foot a lever on the left side of the chain-gear quadrant is depressed and the change-gear lever brought into the starting slot and pushed firmly and quickly down as far as it will go. When the motor starts the lever is released and springs back into neutral position again. As in the past, the Haynes clutch is of the contracting band type on both models, but instead of using a bronze drum this year the drum is of hardened steel. Right control and right drive are maintained for this year on model 22. The starting crank is omitted on both models. Model 24 has just been brought out and is newer than model 22, which was announced some time ago. The first cars of this type to arrive in New York City will be those exhibited at the New York shows.

Henderson—Uses Wire Wheels

Four new models, the 45 Roadster and 47, 48 and 49 Touring car have been placed on the market by tbe Henderson company. The 45, 47 and 49 models are equipped with wire wheels. While retaining the same general features as the previous model 46, touring car, such as gasoline tank on dash, dynamo lighting system and left drive, and using the same motor, the wheel equipment has been altered to suit the new system. An extra wheel is carried at the rear of the car on a false hub. These wire wheels have quick detachable rims of the Marsh type. Models 48 and 49, both five-passenger touring cars, differ from the model 47 in the following respects: Cellular type radiator; combination tail light and license holder; electric dash and trouble light; one-piece windshield with hand holds on bracket and rubber skirt on bottom of shield; Ward Leonard electric starter system; Bosch ignition; clock on instrument board. These bodies will be built on the same standard chassis as 45 and 47 but will be longer bodies with roomier tonneaus, finished in olive green and gray with Turkish upholstering of genuine machine-buffed black and Spanish gray leathers. Model 48 will be equipped with wood wheels of the artillery type, demountable rim and extra rim. Model 49 will be equipped with McCue wire wheels having the Marsh type QD rims and spare demountable wheel. Mechanical features of the Henderson cars are practically the same for all models. The motor is of the block type and has four 4.125 by 5.25-inch cylinders; force-feed lubrication combined with splash; thermo-syphon cooling; Remy dual ignition; Rayfield carbureter, and Ward Leonard lighting system. The gear shift lever placed between the two front seats is retained. The Ward Leonard starting and lighting system is used and has the control handle together with the ignition switch and other dash equipment on a cowl board in easy reach of the operator.

Herreshoff—Makes a Six

Another six-cylinder model to make its first appearance in the 1913 season is the Herreshoff. The motor in this car which is known as the 6-36 is of the T-head type with the cylinedrs cast en bloc and has a bore of 3.375 inches and a stroke of 4 1-2 inches. It is rated by the maker at 36 horsepower and incorporates the three-point suspension feature. A three-bearing crankshaft is used, forged in one piece. The camshaft has also three bearings and is composed of carbon steel. Electric lighting and starting is secured by means of a Westinghouse generator and an 80-ampere-hour storage battery which is wired only to the side and tail lights. The headlights are electric. The wheelbase of this model is 124 inches. Among the other features incorporated in this car are a Herreshoff-Westinghouse electric starter, four-speed gearset, left drive, center control, full platform springs, 34 by 4-inch demountable rims all around with one extra rim, shrouded dash and clear vision windshield.

Hudson—Makes Six and Four

Two brand new chassis, one a six and the other a four, constitute the Hudson line for 1913. The six is known as model 54 and the four as model 37. Both are unlike the 1912 product in every way. The bore of the six-cylinder model is 4.125 inches and the stroke 5.25 inches. The new chassis wheelbase is 127 inches. All types of bodies are fitted to this chassis. Among the prominent features of the six-cylinder car are the cylinders, which are cast in threes, three-bearing crankshaft, pressure feed of oil to timing gears, Zenith carbureter, pressure gasoline feed, and Delco ignition, lighting and starting. Other features about the chassis which are worthy of comment are the use of roller bearings throughout; there are no ball bearings in the car. Longer springs are used on this chassis and 36 by 4.5 tires. The dash equipment differs from last year's in that a

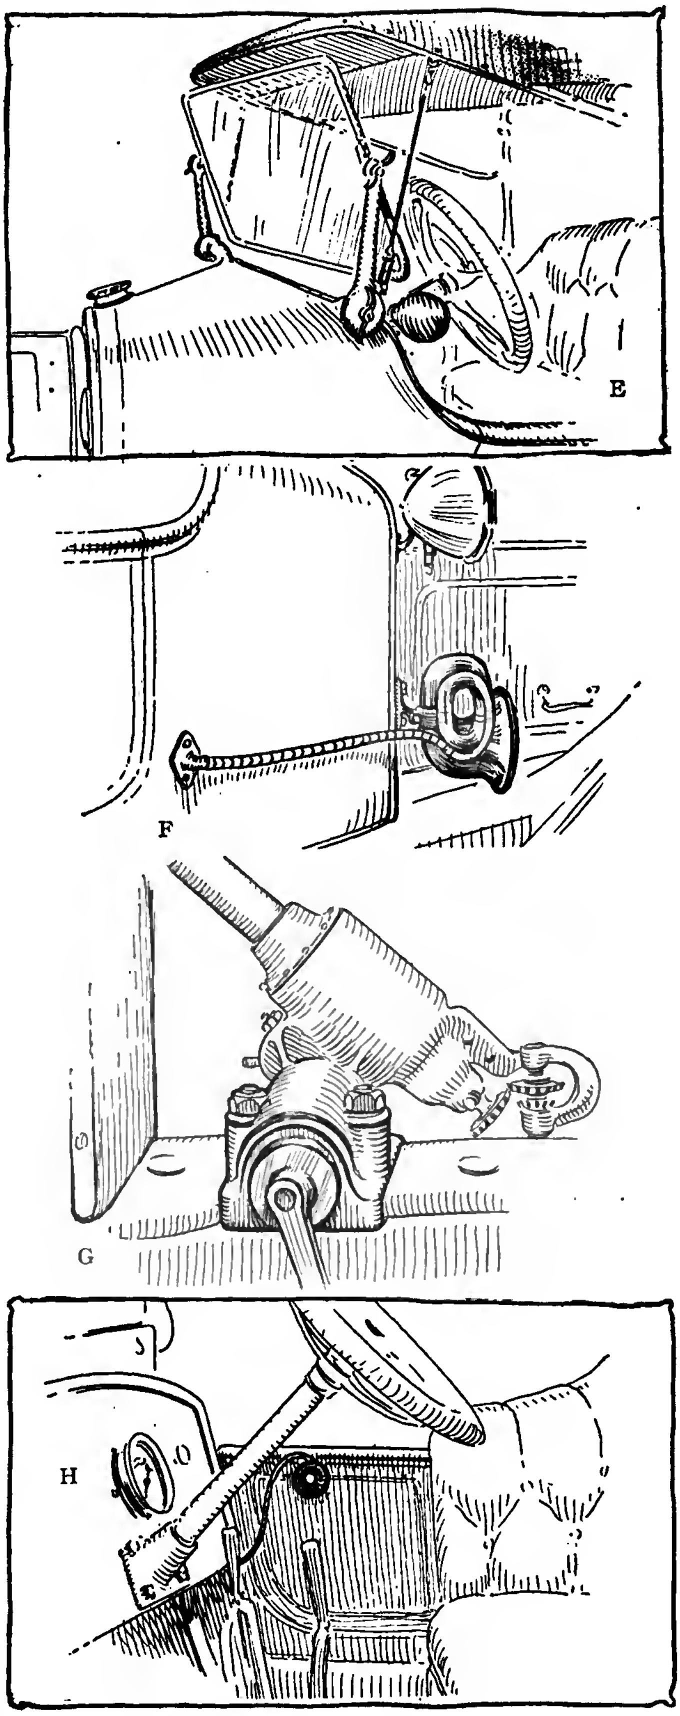

Fig. 11—E, Henderson has done away with the long top strap, fastening same to windshield

F, Hudson has a rigid attachment to the outside of the dash and body for the combination bulb and electric horn

G, Klaxl steering gear is mounted on trunnions on the car frame, and is independent of small deflections

H, on the Jackson car the horn pushbutton can be operated by hand or by the knee, leaving hand free for steering. Center control used speedometer and clock are fitted, and an oil pressure gauge takes the place of the sight feed formerly employed. Right drive and control are retained. Model 37, the four-cylinder car, is also quite different from any of the Hudson company's last year models. It has a new type of motor, the chassis is of radically different design, the self-starting system is different, the location of the gasoline tank is in the rear, and, in fact, an entirely new appearance is made by this car. The motor has four cylinders cast in one block. The bore is 4.125 inches and the stroke 5.25 inches, developing 37 horsepowers at 1,500 revolutions per minute. Interchangeable valves of solid nickel steel operated by conically wound springs are features of the mechanism. The valves are housed in by two large cover plates, which are readily removable. The timing gears are kept to a helical pitch and run in oil. Zenith carbureter is used on this model as in the six, while the gasoline is fed under a 2-lb. pressure furnished by a plunger pump driven off the camshaft. The starting system is the Delco, including the motor-generator and 80-ampere-hour storage battery. The clutch on this car is a multiple disk. The gearset is a three-speed selected type, and is similar in every respect to that used on the 33. A feature of the springs is their length and also the use of a large number of thin leaves which are tongued and grooved to prevent side motion. In addition to this, leaf retainers are used.

Hupmobile—New Six Passenger

With the addition of a six-passenger car on the 32 cbassis the Hupmobile line remains the same as the past year. The springs have been made larger and wheelbase has been increased on the 32, the latter now being 126 inches for the six-passenger car. The 32 touring car and roadster and the 20 roadster are continued. A new body model to be first seen at the shows is a coupé design.

Inter-State—A New Six

A new six-cylinder 45-horsepower motor will lead the Inter-State line for 1913. The motor is of the L-head type with the cylinders cast en bloc. The valves are all inclosed with an aluminum cover. The clutch and gearset being mounted rigidly to the rear end of the crankcase give a unit construction. An important feature of the equipment is the Alpco system for starting and lighting. The gasoline feed is by pressure.

Imperial—New Bloc Six

Five models of Imperial cars are offered for this season, built on four chassis. Most important is model 54, the new 4 by 5.5 en bloc six. It is fitted with electric starter and lights and has a 137-inch wheelbase. The other models are fours. The first of these, model 44, furnished in a touring car type, is very similar to model 44 of 1912, except that the cylinder sizes have been enlarged from 4.5 by 5.25 to 4.75 by 5.25 inches and the car is now equipped with an electric starting and lighting system. It has, furthermore, been lengthened in wheelbase by 2 inches, being now 122 inches. Model 34 differs in the extension of the wheelbase from 116 to 118 inches, and the motor size has been enlarged from 4.3125 by 5.25 to 4.5 by 5.25, and will also be provided with an electric lighting and starting system. Models 32 and 33, touring car and roadster, respectively, on the same chassis, will have a floating axle instead of the former semi-floating type, a motor 4.125 by 5.5 inches instead of 4 by 4.125 and tires 34 by 4 instead of 34 by 3.5 inches. The body types have been greatly improved, especially in the larger models, all bodies used in 1913 being of new design.

Jackson—Makes Big Six

The Jackson company also has its new six for the 1913 season. It is named the Sultanic, and incorporates a 55-horsepower motor and has a wheelbase of 138 inches. The model Majestic, equipped with electric starting and lighting system has a V-shaped radiator of the Metallurgique type. This car has 124-inch wheelbase and 36-inch wheels. All models have 15 gallon gasoline tanks in the rear, from which the gasoline is fed under pressure to a 7.5-gallon supply tank which is located under the shroud. The advantages claimed for this system are that if the air line to the storage tank should get out of order it would be possible to feed from the supply tank direct, the supply tank being located a foot or more above the carbureter and close to it, insures a steady flow of gasoline. All models have 10-inch upholstery, flush-sided bodies and are equipped with Firestone universal, quick-detachable, demountable rims except the Sultanic which has demountable wheels. The Olympic, a 35-horsepower model is equipped with a Disco starter.

Keeton—Follows French Design

Under foreign license, the Keeton, one of the two cars that are outgrowths of the former Croxton-Keeton Company, appear in two models, following French practices in design very closely. The two chassis are very similar in characteristic features of design, differing in size and number of cylinders. The Keeton six features a dynamo electric lighting system, optional wood or wire wheels and a wheelbase of 131 inches. The cylinders of this model are cast in pairs, 3.75 by 5.25, with inclosed valves arranged on the left side. The crankshaft is supporting on three bearings and ignition is fixed. The clutch is of the multiple-disk type, and the gearset, carried amidships, provides three speeds, selectively controlled by a single central lever. Internal expanding brakes on separate drums are provided, each set controlled by pedals, the clutch and service brakes being operated by the same pedal. On the four, cylinders are cast en bloc with manifolds integral, and a bore and stroke of 3.74 by 5.25. Gas starters are employed on both models. Left-hand drive is employed on both chassis, while five-passenger, two-passenger and coupé bodies are provided for each.

King—Makes New Four

In addition to its present four-cylinder type the King Motor Car Company will place upon the market another four-cylinder model, the features of which are somewhat of a departure from those incorporated in the model 36. The cantilever spring of the King, which has always been a distinctive feature, is absent in the new car, which has three-quarter elliptic rear springs and semi-elliptic front. The 36 makes use of half-elliptic rear springs which are mounted with the reverse side up as compared with the conventional construction. Drive through torque tube appears on the new creation as well as on its older running mate. This motor has an L-head design and is monobloc cast. Tbe new motor will have greater power than the model 36. Its dimensions and the type of design to be followed were not yet decided upon at the time of going to press.

KisselKar—Longer Wheelbase

1913 KisselKars are characterized by greater wheelbase, which this year measures 121 inches as compared to 118 inches on the Four-40 of last year; 132 incbes as compared to 124 on the Four-50 and 140 inches as compared to 132 on the Six-60. Some other important changes are the addition of a four-speed gearset on the 40-horsepower chassis, and of electric starting and lighting throughout the line, adjustable pedals, steering column carbureter adjustment and rear tire carriers. The Four-40 and Six-60 have the same bore and stroke, the motor dimensions being 4.5 by 5.25 inches. The Four-30 is a square motor with a bore and stroke of 4.25 inches. The Four-50 has a bore of 4.718 inches and a stroke of 5 inches. All cars are equipped with demountable rims and Timken bearings throughout except in the case of the gearset. Mea magnetos are used and 14 by 5-inch brake drums form a part of the control system. Right drive and control are used on all models. All models use silent-chain driven camshafts.

Krit—Better Equipment

Better equipment is the keynote of the change in the Krit cars for 1913. The trimmings are now nickel instead of brass, an acetylene tank is furnished instead of a generator and a cowl dash is used on the touring car. One change in the 3.75 x 4-inch motor which is of importance in the silencing of the action is the addition of cover plates over the valve stems and tappets. The wheelbase on this chassis remains 106 inches.

Knox—Adds New Six

Four models of Knox cars are now on the market for 1913. A new six-cylinder car which comes under classification of Little Sixes is the feature of the line. The Knox big six, known as model 66, is also continued along with two four-cylinder cars known as models 44 and 45. The two latter are of identical specifications except for the wheelbases. The model 46, or little six, is the only entirely new model added to the line, and while the other three are put out under the 1913 date only minor changes have been found necessary. About the most noticeable features of the new car are the V-shaped radiator which was adopted after the success attained with this type in racing competition, the cover over the overhead valves and the provisions for silence throughout the car. The changes made in the models which have been continued to this year have been principally on the line of body refinement except for one important change in the four-cylinder motor, that is, the increase of the stroke by .75 inch. The stroke of this motor was formerly shorter than the bore, the dimensions being 5 by 4.75 inches, a stroke-bore ratio of .863. The new ratio is 1.1. The other refinements incorporated in the 1913 models include a three instead of a two-blade fan, oil gauge on dash and clock-speedometer arranged on cowl board for easy reference slides over pedal slots. Perkins acetylene starting and lighting outfit, windshield base moved to top of cowl instead of at beginning of cowl, choice of horizontal or vertical tire carrier, changed body lines and concealed door latches. Departures from former usage in this cylinders are cast in pairs instead of singly, as has been former Knox practice. Other departures from former usage in this model are the placing of the intake and exhaust valve on opposite sides of the head, the use of bolted-on in place of clamped-on manifolds, 45-degree conical valves in place of flat-seated valves, springs inside the push-rod guide to hold the roller on the cam for the sake of silence, rounder cam contours, chain drive on the camshaft and magneto shaft. Silence has been made a special feature of the design throughout. To further this object springs are used to take up rattle in all linkage throughout the car, this includes brake connections, torsion lever connections, valve push rods, steering lever, mud-pan hangers, etc. Aluminum covers are fitted over the valve action. Lubricating system on the Knox car is absolutely non-splash. It is what is known as the DeDion circulating system, the oil being independently delivered to all bearings throughout the motor. Among the equipment features are a full electric lighting system and a motor-driven tire pump. Electric starting is optional at extra price. Jiffy curtains are fitted this year.

Lambert—Retains Friction Drive

Lambert model 99, which has been put on the market for 1913, incorporates the latest 40-horsepower Rutenber motor. The bore of this motor is 4.125 inches and the stroke, 5.25 inches. It is of the L-head type with the cylinders cast singly. This motor has the three-point suspension feature, Remy type R. D. ignition with the spark coil for the dual feature located underneath the hood. Two-inch valves for both the inlet and exhaust sides give interchangeability. The drive is taken through a cone clutch while the speed control is governed by the Lambert patented friction drive consisting of a composition disk operating against a specially surfaced wheel. The jackshaft is suspended on Gimbel bearings and the final drive is by Renolds silent chain, 2 inches in width and enclosed within a pressed housing. Full-elliptic rear springs and semi-elliptic front are used. The gear ratio on high is 3 to 1. The weight of the finished vehicle is 2,500 pounds. Beside this model two Buckeye models known as models 10 and 40 are made. These are similar to the larger model, but smaller. The bore and stroke of the model 99 is 4.25 by 5.25 inches, giving a stroke-bore ratio of 1.62. The stroke-bore ratio of model 99 is 1.23.

Lenox—Puts Out Six

A new six with a bore of 4 inches and a stroke of 5 inches will lead the Lenox line for the 1913 season. This new car is different from the old four-cylinder L-head motor in that it is of T-construction. The six-cylinder motor in tests at the Lenox factory developed 61.5 horsepower on the block. It is fitted to a chassis with 130-inch wheelbase, and has a three-speed gearset. Among the features of the design are a large leather-faced cone clutch and a double-jet carbureter. The Gray & Davis starting and lighting system is part of the electric equipment. The latter consists of a motor, generator and a 6-volt 90-ampere-hour storage battery. The starting motor has been added to the regular Gray & Davis lighting equipment, which remains otherwise the same in the new system. A cast aluminum cowl is fitted on all styles of body.

Little—Introduces Six

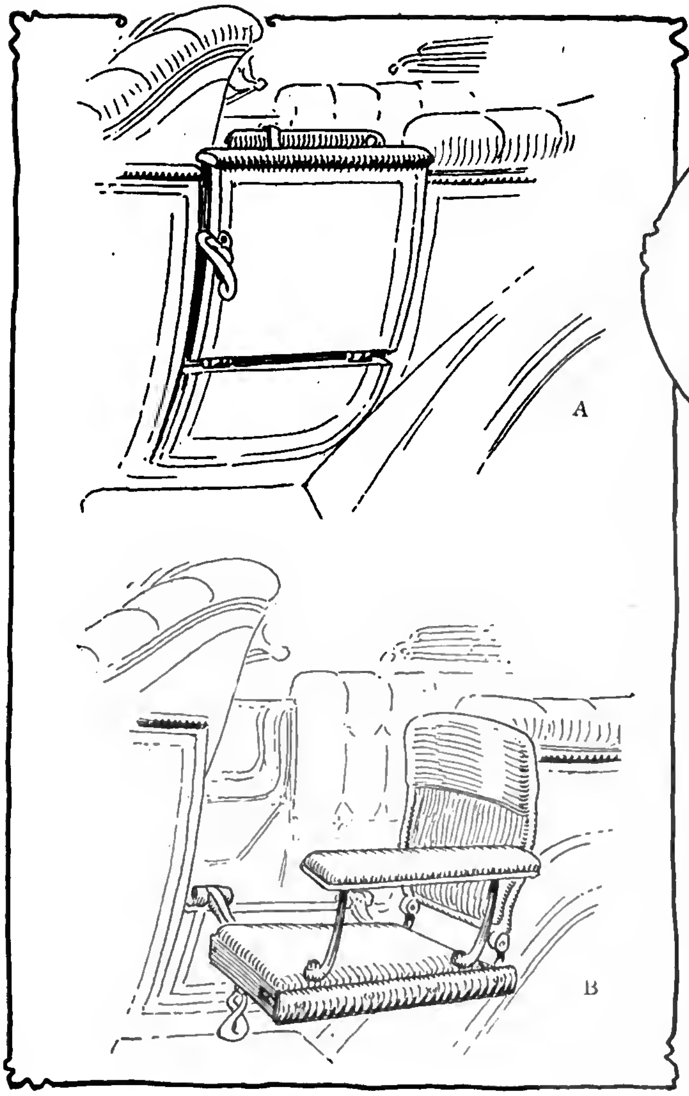
The most prominent feature of the Little line is the new six-cylinder car which has a wheelbase of 106 inches. The motor is of two block castings containing three cylinders each which measure 3 5-16 by 4 1-4 inches. It is of the L-head type. The valves are 1.375 inches in diameter. The motor is suspended at three points. Convex pistons; drop-forged crankshaft and camshaft with babbitt bearings; vacuum oil system; similar carbureter to that used in the Chevrolet; thermo-siphon circulatory system augmented by belt-driven fan are some of the structural details. The front axle is an I-beam section and the rear axle is semi-floating of special design. Brake drums, 12 inches in diameter, are used on the rear hubs. The wheels are 32 by 4 inches and the spring equipment the same as in the Chevrolet. The gasoline tank has a capacity of 18 gallons. Electric lighting is provided for by generator.

Locomobile—Adds a Six

Three models of Locomobile are now on the market for 1913. The newest of these is a little Six, rated at 38 horsepower. The big Six rated at 48 horsepower and the Four rated at 30 are continued. The principal changes to be noted are in the motor dimensions on the larger six-cylinder car. The stroke has been increased to 5.5 inches, necessitating changes in the connecting rods and cylinder lengths. An increase in horsepower has been affected by this change of motor dimensions, 82 horsepower having been developed at 1,800 revolutions per minute. Other changes which may be remarked are the increased valve sizes, changes in form, of the inlet and exhaust passages, and a new design of Locomobile carbureter. The latter differs from the former Locomobile product by its longer throat and the use of both hot air and hot water jackets. A larger magneto takes the place of the former type, while refinements in the oiling system of the 1913 cars consists of the shift of the oil pump drive from the exhaust to the inlet side of the motor. The oil-level pet-cock has been placed on the left side of the reservoir in the motor base, and a new type of oil lead has been designed to give an increase flow to the main bearings. Tires are now carried at the rear on brackets which are a unit with the frame of the car, and the running boards have been left clear to give a clean appearance. A motor tire pump forms part of the 1913 equipment. Electric starting and lighting systems are fitted to all models.

Lozier—Introduces Six

The Lozier light six, which has been introduced this season, is radically different in many respects from the other models produced by this company. Besides having a unit power plant and a motor in which the stroke-bore ratio is 1.52, the chassis involves other features which are new to Lozier practice. The wheelbase is 127.5 inches as compared with 130 inches on the other Lozier model. The cylinders are of the L-head type cast



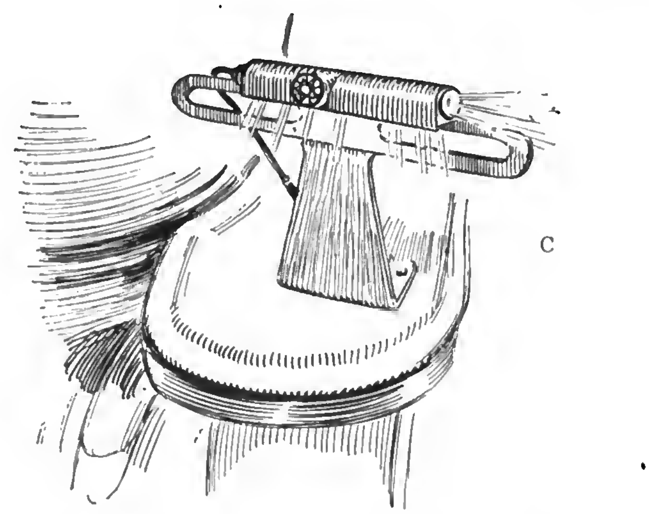


Fig. 12—A, Showing the Lozier door just lifted from its seating before it is swung to a horizontal plane to take the position of an extra seat

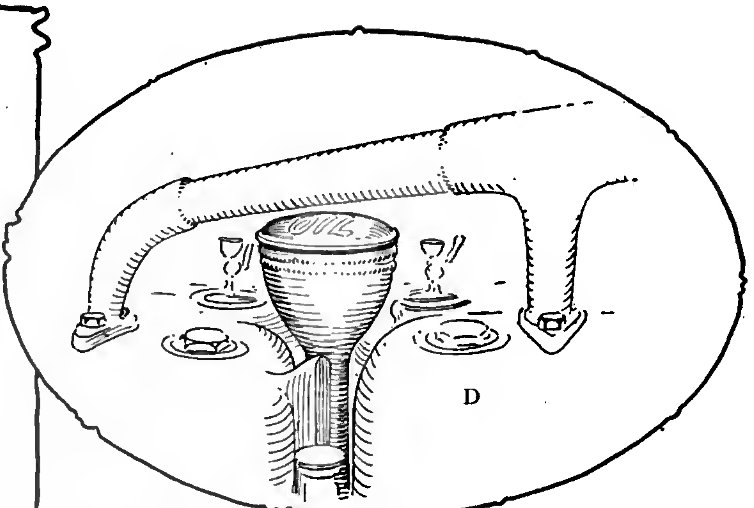
B, Showing seat of Lozier car in position after door has been folded down and arm rail lifted up

C, Rigid license plate holder which is furnished as part of the equipment of the Knox car of this year. It is riveted solidly to the mudguard, and is illuminated by electric light

D, Accessible oil filler hole between the cylinders of the Kissel-Kar



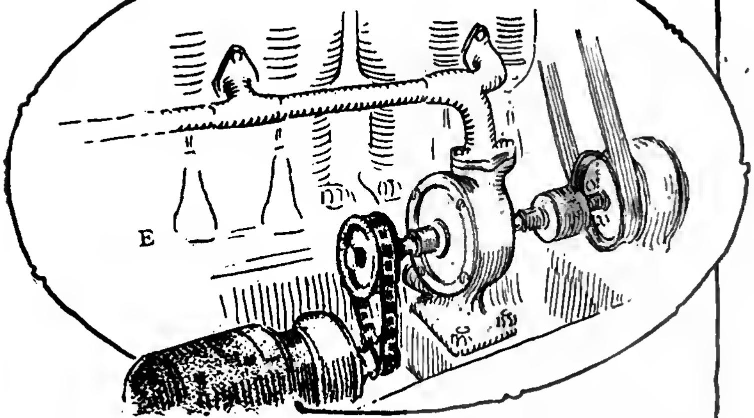
in blocks of three, while the large Lozier motor has T-head cylinders cast in pairs. A new design of intake manifold furnishing a separate connection to each cylinder is incorporated as are cover plates over the valve springs, cast-iron headed valves welded to carbon steel stems, rocker-arm valve lifters, plain bearing crankshafts, spiral timing gears, Bosch dual ignition, pressure gasoline feed, Gray & Davis starting and lighting, multiple-disk clutch with cork inserts on alternate disks, two sets of expanding brakes, and stream line bodies are incorporated. Of special note is the crankcase, the upper part of which is a large rectangle to which the cylinders are bolted and which extends out to the side frame members. This gives a shelf upon which the magneto and the lighting generator may be mounted. The larger Lozier, model 72, will be continued without change.

Marathon—Makes Bigger Motor

Three models of Marathon, designated Runner, Winner and Champion are on the market for 1913. Aside from the new names little difference will be discovered between these models and those which were upon the market last season, with the exception of an increased bore and stroke and the Runner, which was formerly known as the K-20. In all models, however, the axle shafts are incased in a one-piece steel housing, although the floating construction is only used in the two larger chassis, the smaller chassis having a semi-floating axle. The wheelbases have been lengthened in the Runner and Champion models. In the former from 96 to 104 and in the latter from 120 to 123. The Winner has a 116-inch wheelbase, same as in the model L-30 of the previous season. The tires are of the same size except in the case of the smallest model, where they have been increased from 32 by 3 inches to 32 by 4 inches. The springs have been lengthened in all three models to increase easy riding and give more comfort. Other changes in this respect have been the widening of the body and a greater length to give more leg room. In the two larger models the valves are inclosed by aluminum plates, one plate for each pair of cylinders, the castings being made in pairs. Roadster, touring and coupé bodies are furnished on the Runner and Winner, while roadster and touring bodies alone are fitted to the Champion.

Marmon—Uses Left Drive

A Marmon six and four are now on the market for 1913. The six is rated at 48-80 horsepower, and the four at 32-40. The bore of both models is 4.5 inches, and the stroke of the six is 6 inches, while the four-cylinder model has a stroke of 5 inches. Some of the features of construction on both models are force feed oiling through a hollow crankshaft, floating axles, two spark ignition, left steering and center control, cast aluminum bodies with sheet metal seat backs, electric starting and lighting, power tire pumps and combination clock speedometers. Marked differences in designs between the two models are only



seen in the clutch and in the wheelbase. In the four-cylinder model a cone clutch is used and in the six-cylinder model a dry plate multiple disk is fitted. The wheelbase on the four-cylinder model is 120 inches and on the six-cylinder model 145. A castor axle is now on the six.

Marion—Better Spring Material

Marion cars for 1913 consist of four models, two touring cars and two roadsters, and the only mechanical changes announced are small alterations and refinement. English steel in the springs increases resiliency; the throw of the brakes has been increased to give more effect to the retarding forces, and the steering wheel is of the grip type. The cars have been lowered about 1¾ inches; tool boxes are concealed between the running board and the frame, acting also as a dust shield. Decided refinements in body lines have been made, making use of straight flush sides and attractive curves. Cars are completely equipped. The models 36A, 37A and 38A have an acetylene self-starter and the model 48A a Westinghouse electric starter. The motors of the three 30-40-horsepower models are 4 x 5 inches in bore and stroke; the 48A, 4.125 x 5.5. The wheelbases are 112 inches and 120 inches respectively. Upholstery, fittings and small details have received careful attention and have been materially refined, but the mechanical changes over previous models are few.

Mason—Encloses Valves

Two chassis, one with a two-cylinder horizontal opposed motor and the other with a four-cylinder vertical characterize the Mason line for 1913. The double motor has a bore of 5 inches and a stroke of 5 inches. It is chain driven through a planetary gearset, with two forward and one reverse speed. The four-cylinder model has a bore of 4 inches and a stroke of 4.5 inches. The cylinders are cast en bloc with the valves all on the right side. The valve parts are inclosed. A multiple disk clutch, three-speed gearset and shaft drive are used. Both models are fully equipped.

Matheson—Only Sixes

The single-chassis creed has been adopted by the builders of the Matheson. The four-cylinder chassis of last year has been abandoned, while the silent six is continued in a series with past productions and without radical modifications in design. This model is known as Series C, being the third series of the original design of this car. No change has been made on the overhead valve arrangement, the multiple-disk clutch or the rear-axle gearset that are Matheson essentials. The center control and two-spark, high-tension dual ignition were last year's features to which have been added an electric starter and lighting system of Westinghouse manufacture and a full set of shock-absorbers as regular equipment. The chassis is the con-

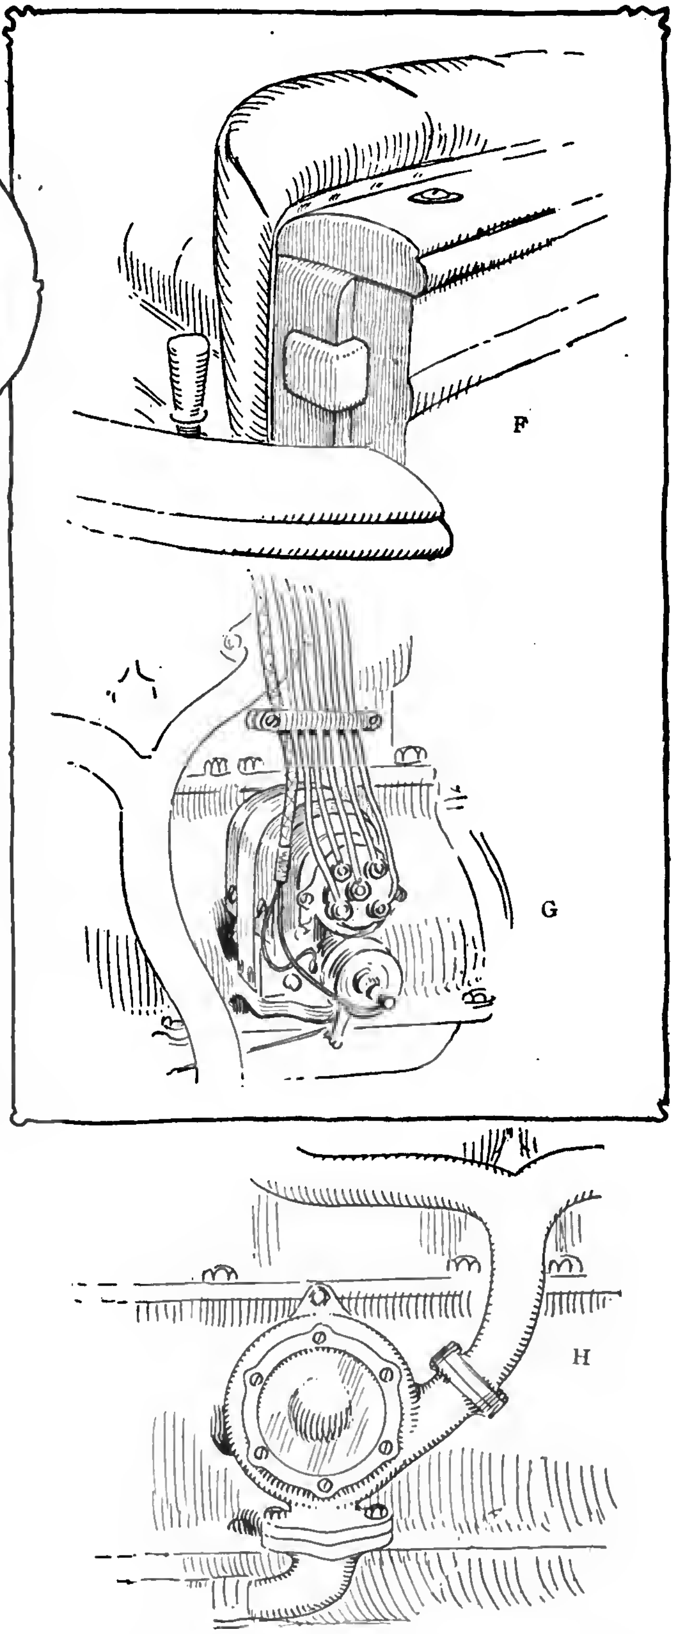


Fig. 13—E, Generator pump and fan drive arrangement on the side of the Lozier crankcase. Note fan casting fastened to crankcase arm

F, Rubber block inserted in door sill of Locomobile car to eliminate slamming noise

G, The magneto and water pump of the National car are driven by a horizontal shaft passing transversely through the crankcase. A bearing is provided on either side of the crankcase in the wall of the latter

H, This view shows the mounting of the water pump on the National car tinuation of the larger of the two sizes made last year, having the same wheelbase of 135 inches. Features in the body details are two sole leather suitcases, side-lockers inside and running-board webs, a new tire carrier, and refinements in the center control quadrant, including a horn bulb in the assembly.

Maxwell—Adopts Left Drive

The Maxwell models for 1913 will number as follows: Three are on a 40-horsepower chassis, one a 30-horsepower, and the other a 22-horsepower roadster. All these models are left drive and center control. The special, which won the Glidden in 1911, has been continued with modifications which will be noted. Instead of being known as the Special, this year's model is known as the 40. In addition to the 40 touring there is a 40 roadster which is an innovation for this season. It is of the touring roadster type, having ample facilities for carrying fuel and tires and is fitted with a waterproof luggage compartment in back of the seat. It can be reached by pulling forward a trap section in the upholstery on the seat back. The 22 roadster which is new this season and which replaces the two-cylinder Maxwell runabout which has been discontinued, is also a new model and is of the conventional small runabout type with the gasoline tank mounted in the rear. It incorporates left drive and center control; progressive gearset 93-inch wheelbase and 56-inch tread. The motor is of the T-head type with the cylinders cast in parts, and has a bore of 3.75 inches, and a stroke of 4 inches. The front axle is tubular and the rear axle semi-floating. The improvements in the model 40 outside of left drive, center control, selective gearset, self-starter, and 36-inch wheels are an increase in the wheelbase and clearance, two foredoors instead of one, spring suspension on underpan, frame lined with leather, and numerous motor improvements which may be noted as follows: Longer connecting-rods, lighter weight pistons with three rings instead of four, relief valves on the engine, larger scoops on the connecting-rod ends, copper inlet and exhaust pipe gaskets, new stuffingbox on the valve push rods, lower compression, new carbureter, new inlet manifold, fan bracket integral with the water discharge pipe, an increased water capacity, and a thermo-syphon cooling system. Throughout the chassis larger bearings have been fitted, notably in the clutch, gearset, steering connections and universal joints. In addition to having the steering wheel on the left and the gear lever in the center the changes which have been made in the control are an aluminum steering wheel, better shaped throttle and spark levers, a more accessible accelerator pedal and greatr breaking leverage. The body dimensions have been increased, the front seats lowered 1 inch and the rear 1.5 inches. In connection with the redesign and improved finish of the body several accessories were added. Among them are upholstery pockets in the tonneau, larger ventilators in the dash, improved hinges on the bonnet and a bulb horn concealed beneath the hood. Improvements in the Maxwell 30, which was last year's mascot, have been along the lines of better appearance. A front axle of dropped forged I-beam construction has been added, the frame lowered, the wheelbase lengthened, flatter spring used, and new design of fenders fitted. On all models the wiring is carried better this year than last.

McFarlan—Adopts Floating Axle

Although basic design in the McFarlan line has undergone little change, numerous minor refinements have been incorporated. Starting with the current season the McFarlan cars will not be made in yearly models, but will be designated in series. What has heretofore been known as the little six will be the series S; the big six will be series M and the new model which has just been added will be series T. The changes which have been incorporated in the line include the adoption of the floating rear axle on all models while heretofore the series M only was so equipped. The front axle has ben changed somewhat, also the steering connections now being behind and above the front axle, whereas formerly they were in front of the axle. All spring bushings are now bronze. The front springs are semi-elliptic, mounted under the frame and the rear springs are scroll elliptics with swivel seats. The most notable feature is an entirely new chassis incorporating a 4 by 6 block motor. Although the cylinder casting is a single unit, four main bearings are used on the crankshaft. The end bearings are 4.5 inches long, and the middle bearings 1.875 inches, the crankshaft is 2 inches in diameter. The motor is of the T-head type and has a fan in the flywheel as well as one directly behind the radiator. The valves are all enclosed giving the motor a compact and simple exterior appearance. With the exception of the motor, and a somewhat heavier clutch the series T chassis is identical with that of series S. The gearset is a unit with a rear axle, and the gasoline tank is mounted on the rear of the chassis giving a pressure feed of gasoline to the carbureter. A few minor changes have been made in the series S motor which are notably as follows: The valves are now enclosed; the motor is hung on three points instead of four; the water pump has been brought forward and the air pump for the starting system set behind it; the air pump is driven direct from the water pump shaft and not by offset gears and the dynamo takes the place vacated by the air pump being driven by silent chain. The series M, formerly the big six, remains unchanged, except for the addition of the electric lighting system, and the shifting of the tire carriers to the rear where all tires are carried in the 1913 models. The compressed air self-starting system, which was a feature of the McFarlan line last season has been continued. It is operated by a four-cylinder Kellogg pump storing air under 200 pounds pressure, and a single tank swung on the right frame member.

McIntyre—Only a Six

McIntyre cars now appear in a single six-cylinder chassis for 1913. This model is known as the 6-40 Limited and it sells at an unusually low price for a car of six cylinders. The motor is of the T-head type with the cylinders included in a single block. Cooling is by the thermo-syphon system, while ignition is dual battery and magneto. A gravity-fed Stromberg carbureter is used. A multiple-disk clutch and four-speed selective gearset is mounted in an extension of the crankcase in one unit, the only visible moving part of the power plant being the fan and road wheels. The rear axle is of the floating type. The wheelbase is 120 inches and the tires 35 by 4. Right-hand drive with center control by a single lever is used and starting is accomplished by an electric starting device. Equipment includes five demountable rims, mohair top and envelope, windshield, electric horn, speedometer, clock and dust cover for the car.

Mercer—Electric Starting

Although abandoning the annual model plan the Mercer company has brought out a new series incorporating four models known as G. H. J. and K. These are mounted on two chassis and are of the following types: Four-passenger touring, five-passenger touring raceabout and roadster. The changes which have been made over preceding series are as follows: The fitting of the Rushmore electric starting and lighting system, replacement of the Bosch D. R. 4 magneto by the Z. R. 4, the addition of a four-speed instead of a three-speed gearset on models J and K, and the substitution of direct drive on fourth speed instead of on third. In the fore-door bodies the control levers have been brought inside and on the model H the body has been widened somewhat. The fuel feed in all models is now controlled by a positively driven pump in place of the exhaust pressure formerly used. The horsepower ratings on model G and H, according to the S. A. E. formula are 32.4 and on Models J and K, 30.6. The wheelbase of the first two models is 118 inches and of the latter two, 108.

Metz—Adds Touring Car

The Metz 22 is continued without change for the 1913 season except that a four-passenger touring body will be fitted to the 22 chassis. The motor is a four-cylinder en bloc casting having a bore of 3 3-4 inches and a stroke of 4 inches. It is cooled by the thermo-syphon system in conjunction with a vertical tube radiator. It has a three-bearing crankshaft, is oiled by splash, has friction drive, left steer and center control. The friction numbers have been improved so that when a renewal of the surface is necessary a two-piece ring doweled together to form a complete ring can be put in place quickly and easily.

Michigan—Adopts Left Drive

Three Michigan models are on the market for 1913. Prominent features of these models are left drive, center control, electric lighting and four-speed gearsets. The motor has four cylinders cast en bloc and is of the L-head type, the valve being located on the right side. Mushroom push-rods operate the valves. The steering post is adjustable, the rake being made to suit the taste of any driver by a simple adjustment. The clutch and brake pedals are also adjustable, thereby making the whole control system to suit the driver's convenience. Either electric or gas starter is furnished at the option of the purchaser.

Midland—Produces a Six

Complying with the popular clamor for medium-priced sixes, the Midland Motor Company has produced a six in addition to the four, which it is continuing from last season. The new six has a T-head motor, 4 by 5 inches with a 135.5-inch wheelbase, 36 by 4.5-inch tires on demountable rims, left-hand drive with control levers in the center, a floating rear axle and the Gray & Davis electric lighting and starting system. The four-cylinder model has cylinders 4.5 by 5.25 instead of 4.5 by 5 as last year's motors measured, and with a 122-inch wheelbase, instead of wheelbases of 115 and 118 as on the former three models. Left-hand drive and center control are also new features. The rear axle is floating and the tires are 35 by 4.5 inches fitted on demountable rims, as in the former models. The Gray & Davis electric system is fitted on this model also, and both models are sold with full equipment. The bodies have been altered to fit the new chassis dimensions and in such redesigning has been brought up to date, and their lines greatly refined and improved.

Mitchell—Underslung Springs

Three types of cars are included in the Mitchell line for 1913, all of which differ from last year's construction in that they have double-dropped frames, with rear springs 7-8 elliptic, underslung, equipped with left-hand steering, center control, and have "T"-head motors of longer stroke in place of the L-head engine used in 1912. The motors of the four and bix six models are cast in pairs. The size is 4.25 by 7 inches. The little six cylinders are also east in pairs, but the displacement is smaller than the foregoing, cylinder measuring 4 by 6 inches. Lubrication is by combination of the circulating and splash systems operated in connection with a gear-driven rotary pump. The carbureter is the latest type Rayfield. Bosch duplex ignition is installed in all models. Cooling, transmission and axles are retained as in 1912, but the driving clutches in the hubs have been eliminated. The wheels are larger, the two smaller models taking tires 36 by 4 inches and the big six being equipped with tires 36 by 4.5 inches. Complete accessory equipment is included in the list prices. This embraces electric starter and lighting system as well as the usual liberal collection of sundries. The wheelbases of the three chassis types are respectively 120, 132 and 144 inches.

Moline—Increases Bore

Increased bore of the cylinders, a greater wheelbase and more drop to the frame are the leading features of the 1913 Moline cars as compared to those of the previous season. The increase in the bore of the cylinders decreases the stroke-bore ratio materially, and this car, which had the greatest ratio in the last season, now drops back among a large number of others possessing the same ratio. The bore of 4 inches and stroke of 6 inches gave a ratio of 1.5. The bore is now 4.125 inches and the stroke remains the same, reducing the ratio to 1.45. Briefly, the motors have four cylinders cast in pairs with the valves on the left side, thermo-syphon cooling, Bosch ignition, Ward Leonard lighting and starting dynamo, and force-feed and splash oiling system. The clutch is a leather cone with cork inserts and has a diameter of 16 inches. The three-speed gearset is carried on roller bearings. A change has been made in the gasoline system, two tanks instead of one being used. The first is located on the dash and has a capacity of 8 gallons. The other is under the seats and has a 12-gallon capacity. Right drive and control are maintained this year.

Moon—Brings Out a Six

Following the undoubted trend of the new season the Moon company has brought out its first six-cylinder model. Electric starting and lighting equipment will also be features for this season, as will the popular left steering and center control. Mechanical changes are few, even the six-cylinder car being nothing but a large edition of the smaller four-cylinder model, having the same bore of 4 inches and a stroke of 5.75 inches. Cylinders are cast in pairs and another pair has simply been added along with the necessary changes in making the six-cylinder model. The other four-cylinder model is rated at 48 horsepower and has a bore of 4.5 inches and a stroke of 5 inches. The latest Stromberg carbureter is used for this season on the Moon cars and for lighting the Wagner system has been employed. The clutch used on the Moon cars is of the multiple-disk type. The gearsets have three forward speeds and are housed within a solid aluminum non-resonant casing. Four-splined shafts are used in the gearset, while a copper-asbestos gasket placed between the cover and the box itself maintains an oil-tight condition.

Nance—Introduces a Six

The Touraine six, a new model turned out by the Nance Motor Company, a newcomer, is using a 4 by 5.5-inch motor, with the cylinders cast in blocks of three. The motors test to 61 horsepower at 2,220 revolutions per minute and are of the T-head type. The self-contained circulating system takes care of the lubrication, the oil supply being carried in the base. A multiple disk clutch with alternate disks faced with Raybestos transmits the power to a three-speed gearset. A straight line shaft drive is carried on crucible steel cross members. Axle is floating; brakes are located on rear wheels and act on 16.625 by .625-inch brake drums; stearing gear with worm and gear type and wheels are optional wood or wire. Wheelbase on the seven-passenger touring model is 134 inches. On the five-passenger Phaeton it is 124 inches and on the special roadster, 112 inches. A double jet carbureter which the makers claim delivers a mileage of 10 to 16 to the gallon of gasoline, is employed on all cars. The lighting is by the Gray and Davis electric dynamo system.

National—Electric Starting

The latest National "40" Series is known as the Improved Series V. Among the newest features of these cars, five of which are called regular models, are the Gray and Davis electric starter and lighting system. These models also include left-side drive; center control, long-stroke motor, 4.875 by 6 inches; tire pump integral part of the motor; Bosch dual double magneto; electric horn; Truffault-Hartford shock absorbers on rear; 128-inch wheelbase; adequate baggage-carrying compartment, concealed but easily accessible; adjustable ventilating and rain vision windshield; multiple jet carbureter; speedometer; tire carrier in rear; gasoline pressure feed tank with gauge in rear; plain, continuous inclosed metal guards; tool chest concealed by splasher and an extra Firestone demountable rim. The tire pump is capable of fully inflating a tire in 3 minutes.

Norwalk—Sixes Only

Six-cylinder cars will be specialized in the Norwalk 1913 line. These are made in two chassis known as Model A and Model B. The Model A underslung Six incorporates a T-head motor of

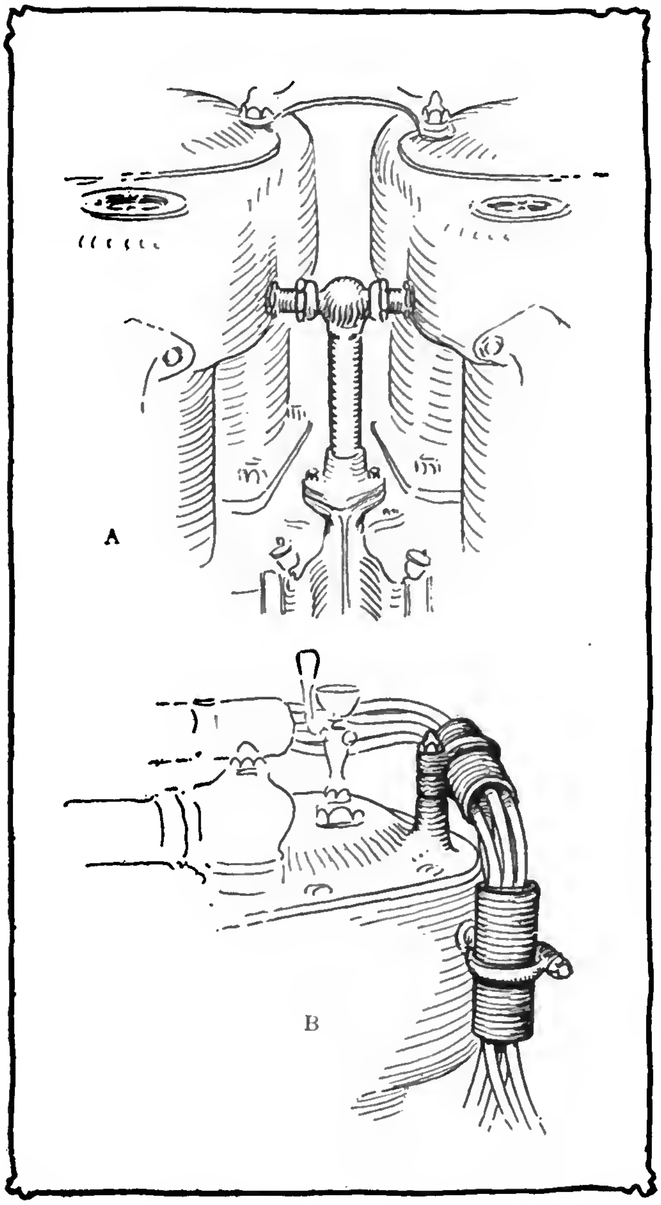

Fig. 14—A, Oldsmobile water intake manifold; B, National wire holder

4-inch bore and 5-inch stroke. The cylinders are cast three en bloc with integral water jackets. The valves are 2.125 inches in diameter and the valve action is covered by removable plates which are rendered rust-proof. A positively circulated splash system is used for lubrication. Among the fittings for the motor are the Carter double-jet six-cylinder carbureter, and the Gray and Davis electric starting device assembled integrally with the motor. The clutch is multiple disk having 30 saw-blade steel disks, each 8.125 inches in diameter and operated by 800-pound engaging spring. Three-point suspension of the motor gearset and clutch is used. Model B underslung Six has a motor of 4.25 inches bore and 5.5 inches stroke. It is also the T-head type and the cylinders cast in three. In general design it is similar to Model A, the valves being inclosed and the same oiling system. The electric starting and lighting system used in conjunction with this model is a unit with the flywheel instead of the Gray & Davis independent unit schemes employed on the other models.

Nyberg—Adds New Four

Four models of Nyberg car comprise the 1913 line. There were three last year, and these are continued under the name of the Four-40, Six-45 and Six-60. To these has been added the smallest car, which is known as the Four-37. The same general construction is employed throughout the four models, and they differ only in sizes of the various parts. On the three larger models two different wheelbases are employed, the small touring cars having 128-inch wheelbase and the large touring car 138 inches. All models have a unit power plant with three-point suspension, inclosed flywheel, disk clutch, rear spring bolted to rear cross-member and semi-elliptic front springs. The Four-37 model incorporated the new long-stroke Rutenber motor, having a bore of 3.75 inches and a stroke of 5.25 inches. Of chief interest in this motor is the fact that the magneto and water pump are located in the front instead of on the side and are driven by the same half-time gear that drives the camshaft. Another feature of this motor is that it is a monobloc casting. Every part of the motor is inclosed. The crankcase is of ribbed aluminum alloy. Ignition is supplied by Remy magneto and a Schebler or Stromberg carbureter forms a part of the equipment also. The two six-cylinder models are listed with full equipment, including electric starter, lights and horn, also top, windshield, speedometer and five demountable rims. Left-hand steering and center control are standard.

Oakland—Adds a Six

Another six to be introduced for the season of 1913 will be that manufactured by the Oakland Motor Car Company. The three four-cylinder types known as models 35, 40 and 42, comprise a group of four-cylinder models. The first of these has a 3.5 by 5-inch motor, while the other two are mounted on the same chassis equipped with a 4.125 by 4.75-inch motor. The cylinder dimensions on the latter are the same as those on the Six-60, which has just been introduced. Having one design in this way permits the concern to standardize a great many parts and thus cut down the cost of manufacture. The wheelbases of all four models are different, being 112, 114, 116 and 130 in the order named above. The difference in construction between the Six-60 and the Four-42 lies in the fact that the motor on the former has its magneto, water pump and camshaft driven by silent Coventry chain, whereas in the four-cylinder motor they are driven by gears. Models 35 and 40 differ from the other two in that their axles are semi-floating instead of floating; they have a single drop frame instead of a double drop; their radiators are flat and not curved or V-shaped; they carry 15-gallon gasoline tanks under the front seats, and feed the fuel by gravity in place of pressure as used on the other models, where the tanks are flung in the rear. A feature of the Oakland line for the coming season is the fact that the running board does not run the entire length of the car on the 42 or Six-60. It is broken in the center and forms two steps, one for the foredoor and the other for the rear. Deaco lighting and ignition will also be features of the 1913 car. Twelve different body types allow a wide range of selection.

Ohio—Makes a Six

Two fours and one six pleasure chassis are put out by the Ohio Company for the 1913 season. On these will be mounted all styles of body. The six and fours are made on the same general styles, the dimensions, however, being different. Six-cylinder car has a wheelbase of 138 inches and a motor of 4.5 x 6 inches. A seven-bearing crankshaft is used on this motor. Left steer and center control are also features. The equipment of the car is very complete, including electric light generator, electric lights, semaphore tail lights, storage battery, trouble finder, 37 x 4-inch demountable rims and customary tool equipment. Models 19, 20, 21, 22 and 23 are mounted on a four-cylinder chassis incorporating a motor rated at 47 horsepower of the four-cylinder type with T-head cylinders cast in pairs. The features of this model are the 2.125-inch valves, the helical timing gears, hot-water-jacketed carbureter and full equipment. The other four-cylinder chassis upon which are mounted models 13, 14, 15 and 16 also includes a unit power plant with three-point suspension. The motor has a 4.25-inch bore and a 4.75-inch stroke; 2.125-inch valves are also used in this motor. The general design of the motor is the same as that mentioned in the four-cylinder motor above.

Oldsmobile—New Light Six

A new light six Oldsmobile has been introduced for 1913. It incorporates a 40 to 50-horsepower motor, electric starting and lighting, three-point suspension, vanadium steel floating axle, 135-inch wheelbase, unit power plant, and a 30-gallon gasoline tank mounted on rear, a one-piece adjustable glass front and full equipment including a motor-driven tire pump. In addition to this car the four-cylinder Defender will be the only other model to be made for the coming season. This has a 4 by 6 motor and is practically the same as for 1912. The bore of the New Six is 4.125 inches and the stroke 4.75 inches. The cylinders are cast in pairs and are given a gray enamel finish.

Only—Now Has Four Cylinders

The Only car which has attracted considerable attention owing to its novel features of design will be continued with practically no changes for the 1913 season. The original car was a single cylinder model but within the last year the motor has been changed to the four-cylinder type. The bore is 4.25 inches and the stroke 7.875 inches. The valves have a head diameter of 2.5 inches and are actuated by roller followers on the cam. The car is guaranteed to operate at 30 miles on one gallon of gasoline and is also guaranteed to attain a speed of 75 miles an hour. The carbureter is a special design having three auxiliary gas and air intakes, the throttle actuating air, gas and gasoline passages at once. Thermo-syphon cooling is used in conjunction with a special design of radiator. The center of gravity of the car is in the same horizontal plane as the wheel hubs. The wheelbase is 112 inches and the tread 56 inches.

Overland—Bigger Wheels

Two Overland models are on the market for 1913. They are known as models 69 and 71 and replace the 1912 models 59 and 61. Although still retaining the principal features of Overland construction, a number of changes have been made in both these models. Model 69, the cheaper of the two, is a four-cylinder L-head type with its cylinders cast separately. The bore is 4 inches and the stroke 4.5 inches. Thermo-syphon cooling, combined splash and force-feed oiling, Remy dual ignition and Schebler carbureter take care of the functioning of the motor. Some of the changes made in this model are oil-tight guides around the valve tappets, oil grooves in the pistons, flanged in place of threaded intake manifold, new type of rear axle which is called by the Overland company a three-quarter floating, brakes increased in diameter to 13 inches, modified brake equalizing device which involves the use of ball-and-socket joints in place of ordinary linkage, the wheelbase has been increased to 110 inches, 4 inches more than last year, making an extreme length for the touring car of 168 inches and for the roadster 151 inches. The design of the model 71 chassis is practically the same as model 69. The motor is larger, having a bore of 4.375 inches and a stroke of 4.5 inches. It is rated at 32.6 horsepower. The differences between this car and the model 69 are its larger motor, and a full set of electric lights throughout, the oiling is all by splash, the three-speed gearset is mounted on the rear axle in the same manner as in the model just described, the wheels are 34 by 4 inches in place of 32 by 3.5 inches as on the model 69, the axle is floating, tool boxes are fitted and on both models, with the exception of coupé types, Presto starters form part of the equipment.

Paige—Adopts Left Drive

The Paige 36 is a new feature of the line of this company for 1913. It involves left drive, electric starting and lighting, silent-chain drive for camshaft, pump and generator and en bloc motor, which is a unit power plant, and other features of a modern nature. The Paige 25, which was on the market last year, has been continued with no changes in construction, a little more expensive equipment being added. The 36, which is now the leader, has a bore of 4 inches and a stroke of 5 inches with the entire motor, clutch and gearset in one unit. The aluminum crankcase is continued back and includes the two other members of the plant. The Gray & Davis system of lighting and starting and Bosch magneto for ignition complete the electric equipment. Both gas and spark control are mounted on stationary quadrants above the steering wheel, while the dash regulator for the carbureter is also supplied. Gasoline feed is by gravity, the tank being installed beneath the shroud and the filler cap being located just forward of the windshield. Nothing is carried on the running board, the tires being mounted on solid brackets to the rear of the car. One auxiliary dash or cowl board carries all the dash equipment, making the switches convenient to the operator. The clutch is multiple-disk with cork inserts, the rear axle is of the floating type, five demountable rims are furnished with the car and license brackets are a part of the equipment.

Packard—A New Six

Of chief interest in the Packard line for 1913 is the little six car, which has just been introduced. It is known as model 38 and incorporates a number of features not to be found in any of the other Packard models. Chief among these are the adoption of the left drive; left control; Delco starting, lighting and ignition; steering column control board for lighting, starting, ignition, carbureter and electric horn. The motor differs from the larger Packard six in that it involves L-head cylinders cast in pairs. The larger six has a T-head motor with cylinders cast in pairs. On the new model the valves are all inclosed by removable cover plates. The valves are on the left side of the motor and the carbureter on the other in the model 38, giving rise to a new shape of manifold for the Packard. This runs between each two blocks of cylinders to the valve side of the motor. According to block tests the rated horsepower of 38, according to the S. A. E. formula, is attained at 800 revolutions

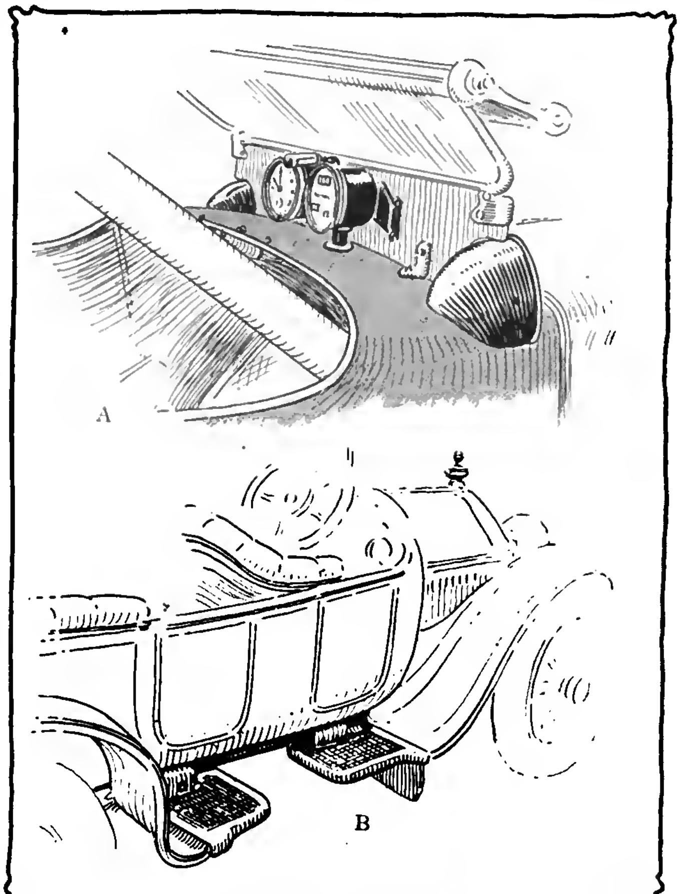

Fig. 15—A, National speedometer mounting above cowl; B, Oakland non-continuous side steps

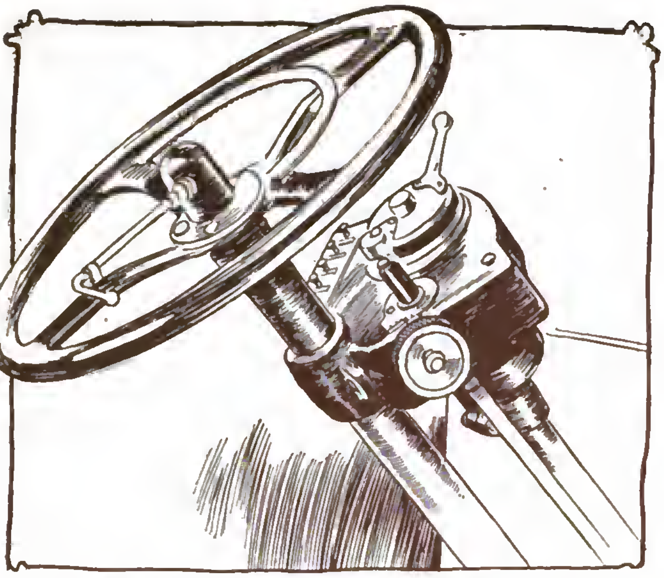

Fig. 16—Packard electric control board on steering post

per minute. The bore of the little six is 4 inches and the stroke 5.5 inches. Other features of interest in this model are the use of exterior brake adjustments, grease cups, the gearset and differential which can be removed as a unit in case of desiring to make any repairs, an auxiliary oiling system which comes into play when the throttle has been opened a distance equal to that necessary to cause the car to go 30 miles an hour on level ground. This is interconnected with the throttle.

Palmer-Singer—A New Six

For 1913 the Palmer and Singer Manufacturing Company is putting on the market a six-cylinder, 60-horsepower model and a six-cylinder, 45-horsepower model. Both of these will be fitted with a two and five-passenger body at the purchaser's option. The Six-60 remains unchanged for 1913. The changes on the Six-40 or Brighton model are the fitting of 36-inch wheels in place of the 34-inch, the floating axle with radius rods connecting the frame and very slight body refinements. The big six has its cylinders cast in pairs and is of the T-head type. A four-speed gearset and multiple disk clutch are also features of this model. The Brighton six has its cylinders cast in triplets, is of the T-head type with 4 by 5-inch cylinders, and uses a three-speed gearset and a multiple disk clutch. The wheelbase on this model is 127 inches, and on the Brighton 138 inches. Electric lighting and air starting and tire pumping outfits are included in the equipment of both models.

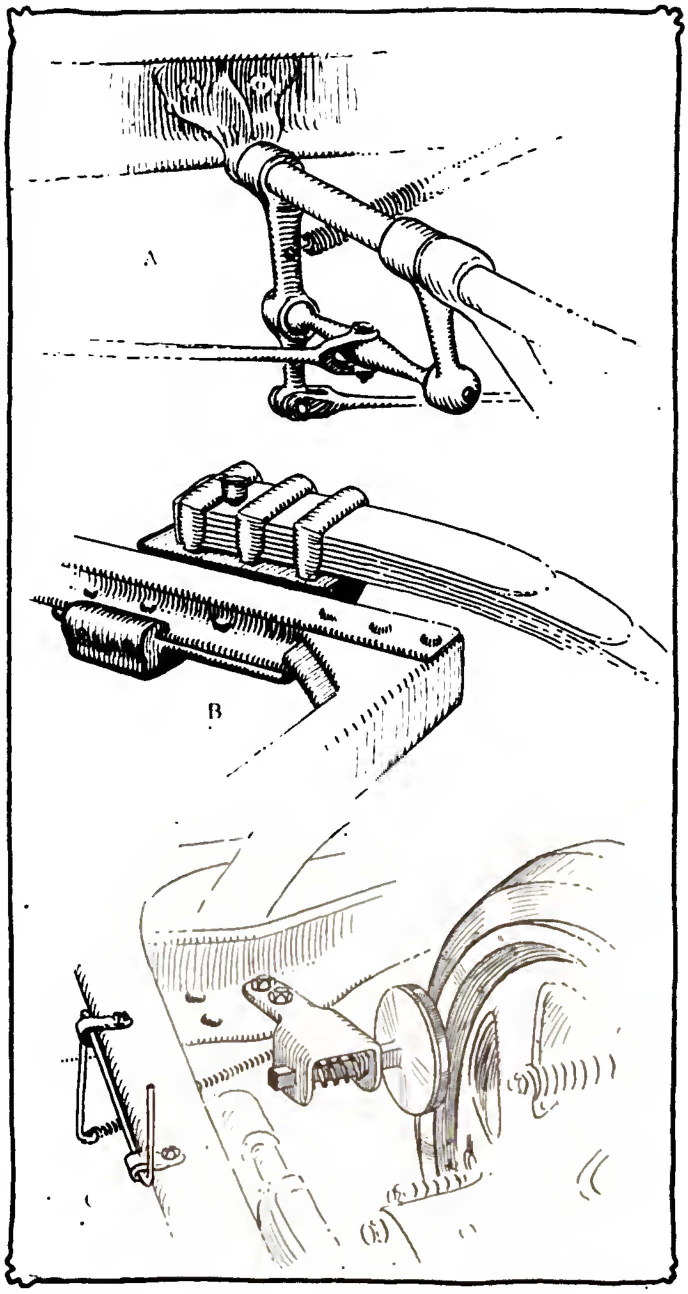

Fig. 17—A, Overland brake equalizer; B, Overland triple spring clips; C, Overland clutch brake

Paterson—Unit Plant

Four models comprising two chassis constitute the 1913 line of the W. A. Paterson Company, Flint, Mich. On the smaller chassis are built models 43, 43-A and 41, identical except in equipment. On the larger chassis is built model 47. The chassis of model 43 has a motor of four cylinders, 4.13 by 4.75 inches, cast in pairs with valves on the left side. Their mechanisms are fully inclosed and the motor, flywheel, clutch and gearset are assembled as a unit. The clutch is of the cone type, and the gearset provides three speeds forward and one reverse. An electric lighting and starting device is installed and demountable rims. The rear axle is of the floating type, the wheelbase is 116 inches and the tires are 34 by 4 inches. Type 47 has a motor of 4.5 by 5.25 inches and a wheelbase of 122 inches, with 36 by 4-inch tires. The smaller models are all provided with five-passenger bodies, while the larger carries seven pasengers.

Pathfinder—Electric Starting

Instead of four models the Pathfinder line for 1913 consists of six, all mounted on one chassis. No radical changes have been made in the chassis except those that would be entailed by the installation of the Gray and Davis electric starting system. The motor is the latest Continental type of L-head design with cylinders cast en bloc. The bore is 4.125 inches, and the stroke 5.25. The motor develops 42 horsepower at 1,330 revolutions per minute. Lubrication is taken care of by two plunger pumps, one delivering a stream of oil to the gears, and the other to the main bearings in the crankcase. Thermo-syphon cooling is used; a cone clutch; three speed gearsets; irreversible steering and chariot type wheels.

Peerless—Refines Motor

Pioneers in 1913 announcements, the Peerless Company produces for the new year five models whose features differ from former productions only in refined detail, as yearly models are contrary to the manufacturing policy of this company. The Bosch double-dual ignition system tried out in the 1912 cars has been discarded in favor of the simple dual system for reasons in simplicity. The piston throttle valve formerly used has been abandoned in favor of the damper type. The Gray & Davis lighting generator is now driven from the fan shaft instead of from the pump shaft, and operates at higher speed. A unique arrangement is provided to prevent loss of oil through leaving the oil drains in the crankcase open. This consists of a lever linkage which makes it impossible to close down the hood with the oil petcocks open. A small force pump on the dash is provided to prime the motor by drawing gasoline from the float-chamber and spraying it into the valve chambers. The models are designated 38, 48, 60, all sixes, and 24 and 40, fours. The Gray & Davis lighting and starting system is regular equipment on all models.

Pierce-Arrow—All Sixes

While the Pierce-Arrow line is continued with three six-cylinder models as has been the policy of the company for years since it dropped four-cylinder constructions, all three models have undergone a thorough housecleaning which places them

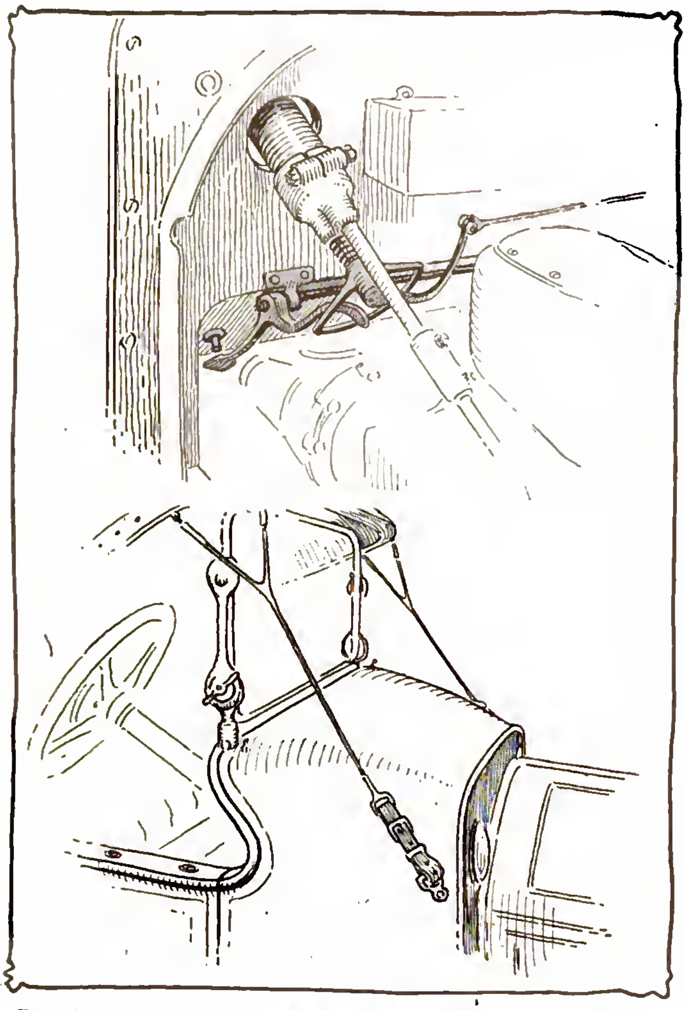

Fig. 18—A, Paige throttle and spark cam control; B, Oakland top strap attachment

much in advance of other makes in not a few engineering details. While generally classed as conservative this company has also been a pioneer, and when changes were deemed improvements, there never was any hesitation in making them, irrespective of other makers. This year shows much improvement and some pioneering. Only one model has a larger motor, namely the 36, which has been changed to 38, its stroke now being 5.5 inches instead of 5.125 inches. It has larger valves and more power, hence the increase in its rating. Now for the general improvements that agree in all models. Gravity motor oiling is superseded by direct pressure feed up to 20 pounds to seven crankshaft bearings and gears, and thence to cranks and wrist-pins. The old gravity oil tank above the cylinder is gone and the motor looks much cleaner. It is still a non-splash system. A compressed air starter is fitted. The 200 pounds air pressure is created by a four-cylinder pump mounted on the front end of the gearbox and driven from the gearset countershaft. It delivers to a reservoir on the chassis from which the motor draws. In addition to this there is the usual air piping and air distributer with dash control. The gasoline primer on the dash connected with a nozzle in the manifold to facilitate starting, is continued and now all models are fitted with compression releases. The carbureter has been overhauled. It is a two-jet design; the auxiliary nozzle located in the juncture of the auxiliary air passage with the mixing chamher does not come into operation until speeds of 800 or over are reached and the auxiliary air valve has opened. The two nozzles give better motor performances on low and high speeds. The needle valve in the main nozzle is improved by a protection, which prevents the tapered end of the valve being injured when screwed up to finer adjustments. Leather disk couplings now are used in the magneto and water-pump shafts. These are quiet. Leaving the motor there are several other improvements. The German bronze facing on the clutch cone has been dropped and leather substituted, it being lighter and thereby facilitating gear-shifting. Another clutch improvement is that the clutch rocker shaft is shorter than formerly and carried on two brackets from the motor rear support instead of the frame side members. Electric lights are standard, the motor carrying a Westinghouse generator.

Pilot—A New Six

In addition to the 40 there is a Pilot 50 on the market for this year and also following the general trend a six-cylinder, 60-horsepower model. All three models have T-head, Teetor motors. Both four-cylinder models have a bore of 4 1-2 inches, the strokes being 5 inches for the model 40, and 6 inches for the model 50. The Six-60 has a bore of 4 inches and a stroke of 6 inches. All three models are fitted with floating axles, Brown-Lipe differentials, semi-elliptic, front and rear springs, cone clutches. Electric starting and lighting is also a feature with the Pilot line this season.

Pope-Hartford—New Four

Electric lighting and starting and one new model have been added to the Pope-Hartford line for 1913, making a total of three models on the market for 1913. They are known as the 31, 33, and 29, and are rated at 40, 50 and 60 horsepower respectively. The new model 31, rated at 40 horsepower, is made in five body styles, a touring car, phaeton, roadster, limousine and coupé. It embodies a four-cylinder motor cast in pairs having a

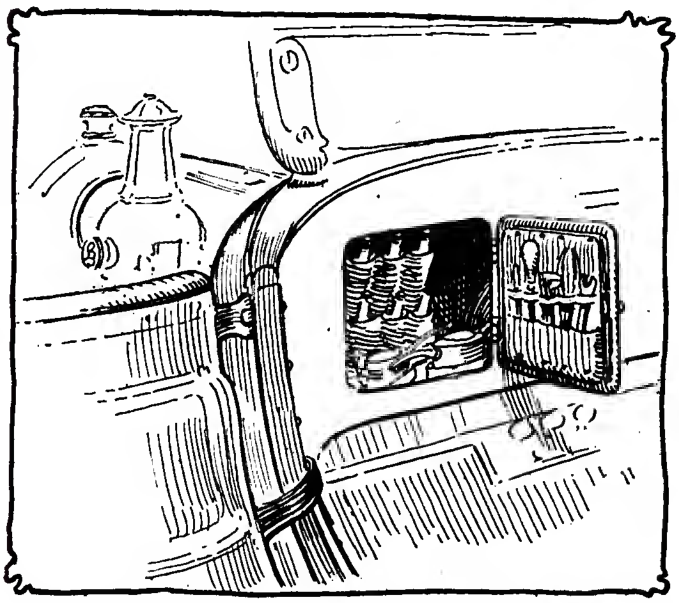

Fig. 19—Pierce tool boxes mounted in dash on either side

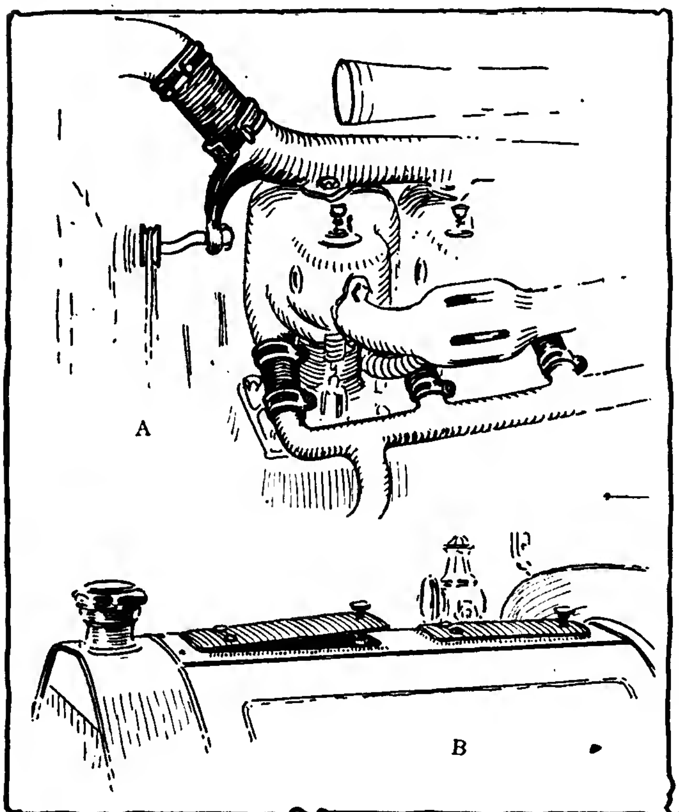
bore of 4.3125 inches, and a stroke of 5.125 inches. The Pope-Hartford carbureter which has been used in connection with Pope models in the past is fitted to this new model. A planetic radiator of distinct Pope-Hartford design is a feature of the cooling system while the ignition is taken care of by Bosch dual system. A leather-faced cone clutch with cork inserts transmits the power to a four-speed gearset having its direct drive on fourth and composed of chrome nickel steel gears, and shafts mounted on Timken roller bearings. The worm-and-gear steering is used and another feature of the control is the double brakes acting on drums of 15.5 inches diameter with 2.5-inch faces located on the rear wheel. Thirty-six by four and one-half wheels running on Timken roller bearings are used all around and are fitted with Firestone demountable rims. A metal body with mahogany dash hooded and provided with a panel in front of the forward seat is used on this car. The tool box is connected rigidly to the body of the car at the rear and is composed of pressed steel. The gasoline tank is removable and can be removed without removing the body, and has a capacity of 18 gallons. Gray and Davis starting has been fitted to this model. The big four-cylinder model rated at 50 horsepower, having a bore of 4.75 inches and a stroke of 5.5 inches, has been continued and numerous improvements and refinements incorporated. Among these are the addition of the Gray & Davis electric lighting and starting systems, a more complete equipment including adjustable windshield, cape top and curtains, trunk rack, demountable rims, etc. The Pope-Hartford model 29 six-cylinder rated at 60 horsepower is similarly equipped and is now in its third year. Among the features of the six-cylinder model are the double drop frame, its four-speed roller bearing transmission, full floating roller bearing rear axle.



Premier—Only Makes Sixes

Starting with this year the Premier company has abandoned the manufacture of four-cylinder models and has concentrated its attention on two sizes. The big six car is practically the same as that marketed as the model M six of 1912. It has the 4.5 by 5.25-inch motor cast in pairs. The little six is a new model but differs only in the size of its motor and in chassis dimensions from the big six. In the latter the only change of importance from the 1912 style construction is the use of a universal joint in place of the ball joint formerly used in the steering-rod connection. In general, it may be said that Premier construction embodies a T-head motor with a movable disk clutch as a unit working through a three-speed sliding gearset to bevel-gear rear axle. The motor of the little six, with a bore of 4 inches and a stroke of 5 inches, has its cylinders, unlike the big six, cast in threes. As is customary with Premier practice, the upper water-jacket is a light, removable aluminum plate. The valves are inclosed by aluminum side plates, which are readily removable, and are operated by push-rods having rollers 1 inch in diameter. The cooling system is so arranged that should the pump become disabled a natural thermo-syphon action would be set up and the danger minimized. Left drive and center control are features of the 1913 Premier, as are also the spare tire carrier on the rear and the gasoline filler pipe between the two front seats, which may be reached by lifting the seat arm.

Pullman—Drops One Model

Instead of four models the Pullman company has placed three on the market for the coming season. The models made this year are known as the 4-36, 4-44 and 6-66. The first number in each case refers to the number of cylinders, while the second refers to the rated horsepower. Last year the models were known as the 4-30, 4-40, 4-50 and 6-60. The 4-50 has been dropped and the other three continued with modifications. The principle changes lie along the lines of improvement in manufacture, the selection of better material and working to closer limits. For all three models the following changes will be noted: Larger radiators, lighter wristpins, dash carbureter primer, larger steering wheel and longer springs, both front and rear. Besides

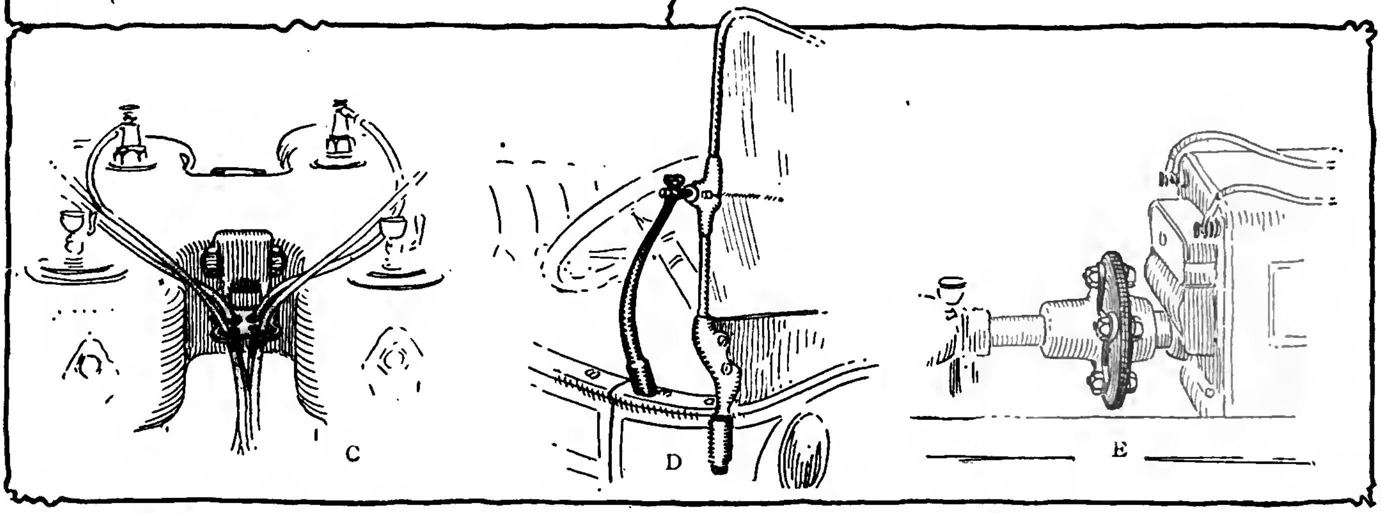


Fig. 20—A, Maxwell rubber water manifold connections; B, Pierce hood cover plates; C, Pullman wire clip; D, Peerless windshield bracket; E, Pierce leather-disk magneto drive coupling

these there are changes which have only been made on the 4-44 and 6-66. These include a new and stiffer crankcase bottom pan, an extra bearing on the camshaft, a dash oil control, a flywheel 2 inches larger in diameter, and extra bearing of the shifter dog of the gearset, an electric lighting generator and, on the 6-66 only, embossed yokes on the rear wheels. Careful manufacture throughout the entire chassis is shown by the use of nickel-steel bolts, the cam contours are the same for all models and grinding work in this field is standardized. Bosch dual ignition is used on all models. An Ever-Ready starter is fitted to the larger models, while a feature of the equipment is an electric vulcanizer.

Rambler—Electric Starting

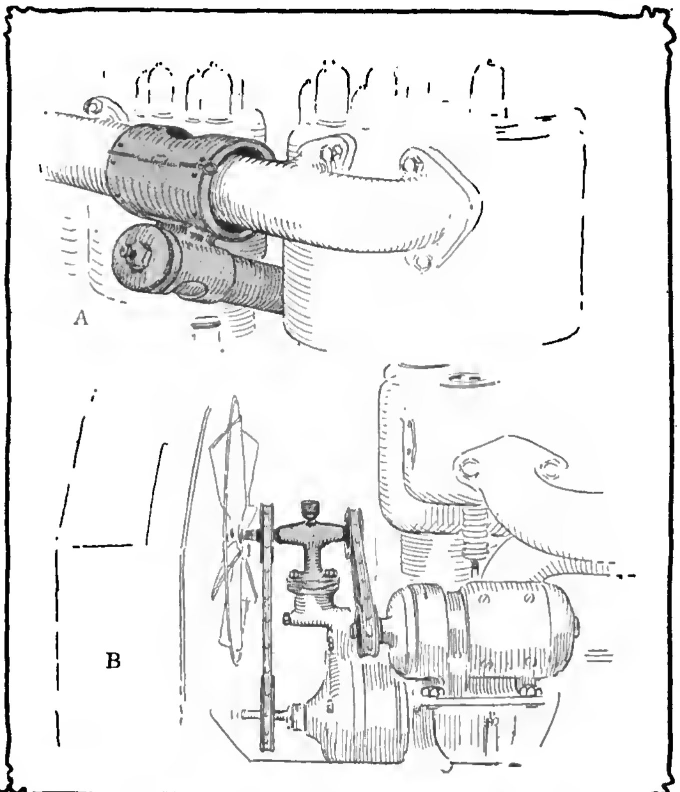
A new Rambler model is now on the market for 1913; it incorporates what the makers call a gasoline-electric motor. The starting system being combined with the flywheel end of the motor in such a way as to be a unit with it. Other changes in the Rambler line, which are all made on the single chassis embodying the 4.5 by 5-inch motor, include the adoption of the cone clutch, a modification of the gearset giving a 1-inch shorter gear shift, adjustable steering column upon which the angle of rake may be altered, and, in the motor, larger valves, a Stromberg carbureter, longer connecting-rods and a better placing of the wiring. The offset construction of the cylinders has been continued as in the past. A new oiling system composed of the Detroit mechanical oiler of 2 gallons capacity mounted on the side of the motor and its corresponding leads to the cylinders and bearings, has been mounted on the 1913 car. The new radiator introduced for the 1912 season has been continued. Three-point suspension is continued for this season, a tubular cross-piece 2 inches in diameter forming the front supporting member. The entire motor is mounted on a slant to secure straight-line drive. In place of the expanding band type of clutch, which has been a Rambler feature, a leather-faced cone has been fitted. Instead of two brake rockershafts which were formerly carried separately, there is now but one, which is a combination of both, one within the other. The U. S. L. starting system consists of a motor-generator mounted integrally with the flywheel, a foot control, an automatic switch, and accumulator, a regulator and a large conduit.

R-C-H—Long Wheelbase Roadster

Full equipment is the slogan of the R. C. H. company and nothing has been spared in doing everything possible in this way for the new line. Little change in constructional details have been made, the principal innovation being the introduction of the long wheelbase roadster. This is placed on the touring car chassis of last year, the roadster of the 1912 season having been mounted on a chassis of shorter wheelbase. Electric lighting, rear-vision mirror, top cover, slip, Jiffy curtains, extra rim holders and Warner auto-meter are a part of the equipment which is fitted to these cars. Other refinements in the nature of changes are the mounting of the throttle control lever on the steering column and the mounting of a hand emergency brake, which was omitted on last year's car. No change whatever has been made in the four-cylinder monobloc motor. The gearset is mounted as a unit with the rear axle.

Regal—Overslung Model

In addition to the line of underslung cars, the Regal company has added a model which has the frame suspended over the axles. The new design is called model C and is a five-passenger touring car incorporating a new motor which has been specially designed for this chassis. The other models, of which there are four, are made on two chassis types, models T, N coupé being mounted on the smaller of the two and models H and S on the larger. These are both four-cylinder models and differ only in size. The new model has a four-cylinder monobloc motor with



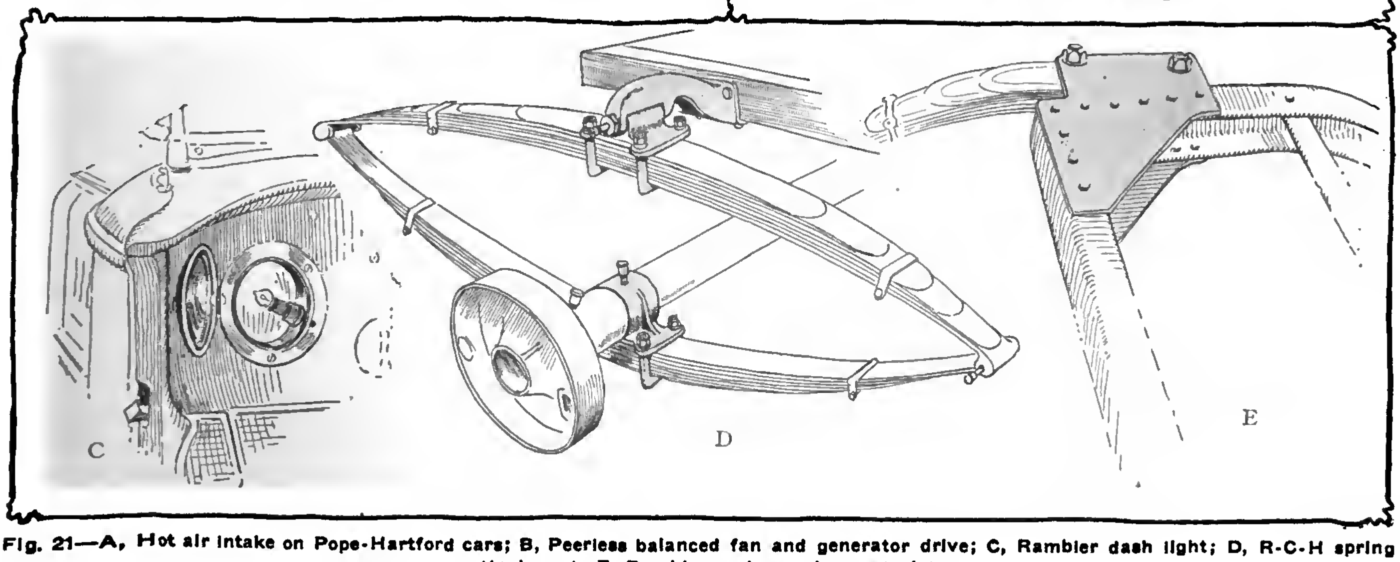


Fig. 21—A, Hot air intake on Pope-Hartford cars; B, Peerless balanced fan and generator drive; C, Rambler dash light; D, R-C-H spring attachment; E, Rambler spring and gusset plate

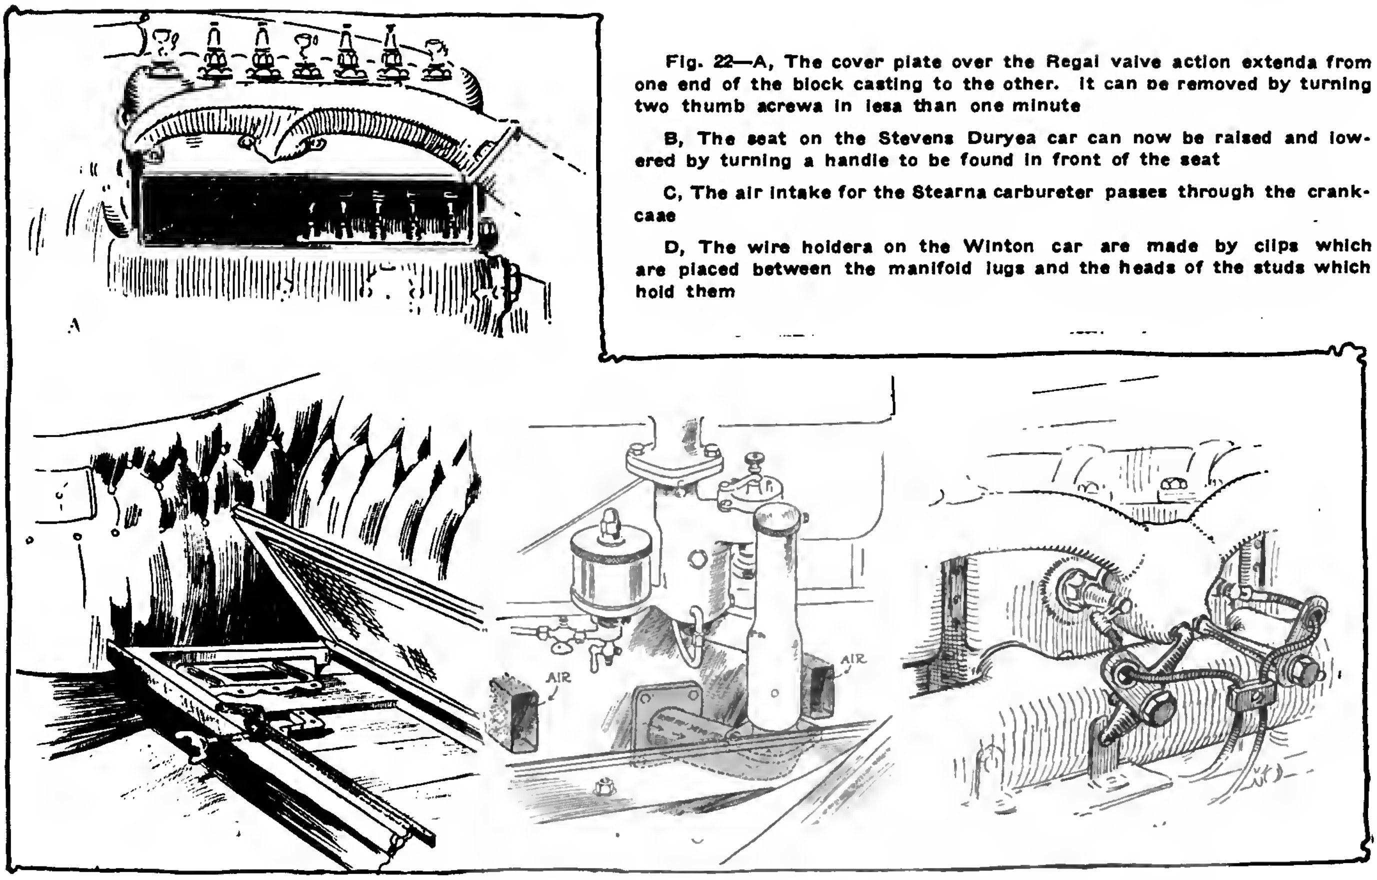

Fig. 22—A, The cover plate over the Regal valve action extends from one end of the block casting to the other. It can be removed by turning two thumb screws in less than one minute

B, The seat on the Stevens Duryea car can now be raised and lowered by turning a handle to be found in front of the seat

C, The air intake for the Stearns carbureter passes through the crankcase

D, The wire holders on the Winton car are made by clips which are placed between the manifold lugs and the heads of the studs which hold them

a bore of 4 inches and a stroke of 5 inches. The exhaust passages are integral with the block casting. The crankcase is aluminum and contains the constant-level splash system of lubrication. The clutch, gearset and springs are very similar to those used on the former Regal model, the frame, however, differs from the former frames in that it is overhung instead of the underslung type. The overhung frame permits of a direct suspension of the motor from the frame and three-quarter elliptic springs. Electric lights, demountable rims and speedometer are part of the equipment. Small changes in body construction, such as furnishing a greater curve to the seat backs and placing of fittings, form about the only changes in the models which have been continued.

Reo—Better Body

Among the improvements made by the Reo concern are greater size of tire both front and rear; electric side and tail lights, and a more expensive magneto. The motor which is rated at 30 horsepower, has four cylinders, cast in pairs. The bore is 4 inches and the stroke 4.5 inches. The valves are in the head of the cylinders. The carbureter is jacketed both for hot air and hot water. The 1913 body is wider and longer than that of the previous year, and it is also more highly and comfortably finished. Seventeen coats of paint are given the bodies while the hood, fenders, etc., have two coats of rubber enamel baked on. Left drive and center control are maintained. A storage battery provides current for the dash and tail lights which are of the combination electric and oil type.

Republic—Adds a Six

The most important development in the Republic line is the addition of the six-cylinder, 4.5 by 5-inch motor. This has its cylinders cast in pairs and its 2.25-inch valves on opposite sides of the cylinders. It is equipped with a special Stromberg carbureter to which the gasoline is fed under a pressure system. The gearset has four speeds and reverse. The clutch is a leather-faced cone with cork inserts. The wheelbase of this car is 133 inches. It is made in four standard styles of body, for two, four, five and seven passengers. It is magnificently upholstered and fully equipped. Delco lighting, starting and ignition is used. The Republic four appears on the 1913 market little different from a year ago. Small refinements have been made, and the equipment is more complete. The later production will be known as Series E and will embrace one more body than was offered prior to this series. This body is a two-passenger runabout which is applied to the same chassis as the other body styles, with the exception the 34 by 4-inch tires are used instead of 36 by 4 as on the other types. The leather-faced cone clutch with which the Republic is equipped is this year fitted with cork inserts. A special feature of the roadster is a trundle auxiliary seat which pulls out over the running board from beneath the front seat. An electric generator furnishes current for lighting and ignition.

Schacht—Electric Starting

The Schacht line for 1913 consists of two distinct body models built on one standard chassis. The touring model, N-S, and the model K-L roadster are both of the fore-door type. The motor for this season is 4.25 inches bore by 5.5 inches stroke and both cars have a wheelbase of 120 inches. Another feature of the line for this season is electric lighting and starting system which is operated with generator and storage battery. The cylinders on the motor are offset .625 inch from the center of the crankshaft. All bearings are Parsons white brass, and the crankcase is an aluminum casting. Floating rear axle, left drive and center control, 36 by 4 demountable rims, with one extra, and deep upholstery are features of this year's car.

Selden—Single Chassis

In conformance with its previous manner of production, the Selden enters the 1913 market with a single chassis, continued with few changes from former years. The effort that has been expended on the new series has been directed towards development of the design, in close adherence to former ideals. The Selden four-cylinder motor is practically unchanged, while the

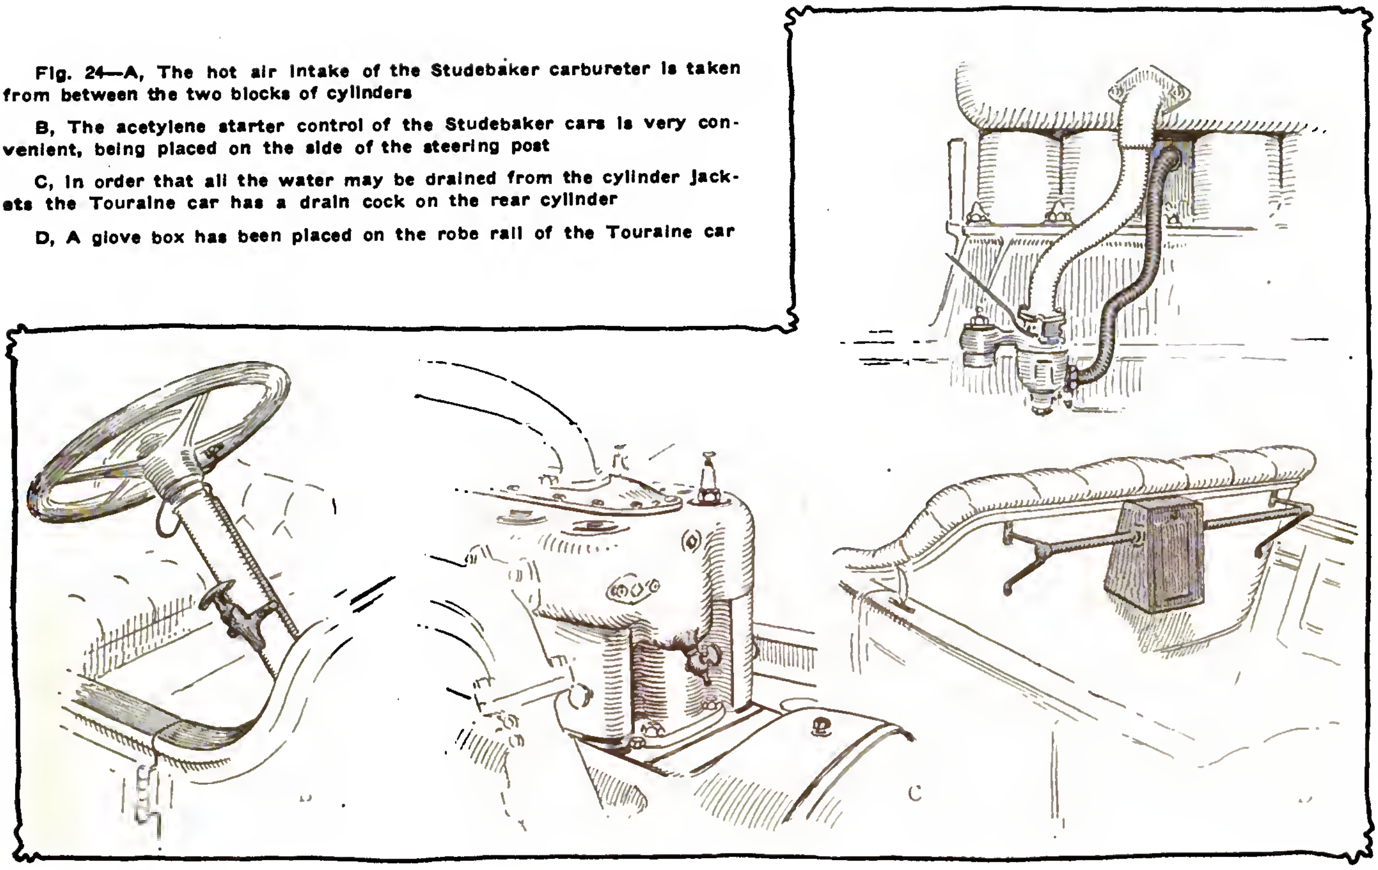

Fig. 24—A, The hot air intake of the Studebaker carbureter is taken from between the two blocks of cylinders

B, The acetylene starter control of the Studebaker cars is very convenient, being placed on the side of the steering post

C, In order that all the water may be drained from the cylinder jackets the Touraine car has a drain cock on the rear cylinder

D, A glove box has been placed on the robe rail of the Touraine car

dry multiple-disk clutch, adopted last year, has undergone no modifications. The principle changes are in the rear axle and in the use of the Gray & Davis starting system, in addition to the lighting system formerly employed. The brakes, formerly both internal, 14 by 1 3-4 inches, have been changed. The service brake operates on the outside of the same drum on which the internal emergency brake operates. The size of each has been increased to 16 by 2 inches. Five body styles will be furnished on this chassis, consisting of a two-passenger roadster, a four-passenger torpedo, a five-passenger touring car, a seven-passenger touring car and a seven-passenger limousine.

S. G. V.—Pressure Gasoline

The only change noted on the S. G. V. model is the substitution of pressure in place of gravity fuel feed on the Model A. Otherwise the line remains the same. The model D, 35-horsepower, differs from Model A, in that there are only three motor gears instead of five, the pump and magneto being operated on the same shaft. There is a spark advance on the Model D and none on the Model A.

Speedwell—Adopts Rotary Valve

Speedwell has made a most radical change in their policy for 1913. The rotary Mead valve motor has been adopted for a six-cylinder car just put on the market. The valves consist of two rotating cylinders carried in the head of the combustion space. They are driven by silent chain from the crankshaft and are lubricated by the oil which is mixed with the fuel. The cylinders have a bore of 4.125 inches and a stroke of 5.25 inches. The cars are equipped with Wagner starting and lighting system. The Mead motor weighs 754 pounds as compared to the 824 pounds of the poppet type used by the Speedwell company. Both have the same cylinder dimensions.

Staver—Adds a Four

Three Staver chassis will be on the market for 1913. They will be known as the 45, 55 and 65. The latest model, and the one which has been added to the line for this season, is the 45. It has a 4.5 by 5-inch motor giving an S. A. E. rating of 32.4 horsepower and developing on the brake, according to the makers, 49.6. The motor is of the T-head type with the cylinders cast en bloc. It is mounted on a sub-frame consisting of parallel members swung inside the side members of the main frame. An electric starting and lighting system is fitted to the car, although air starting is optional with the purchaser. Working in conjunction with the motor there is a Rayfield carbureter, Remy R. D. X. magneto, honeycomb radiator, and a splash system of lubrication. The clutch on this new model is a 38 disk type running in oil. The gearset has three speeds forward and is carried on Rhineland imported ball bearings. Left drive and center control has been incorporated, and all pedals are adjustable to suit the leg length of the driver. Semi-elliptic front and three-quarter elliptic rear springs are used held by a new type of double spring clip which is of square section to prevent loosening of nuts.

Stearns—New Knight Six

Although continuing its Knight type of motor practically unchanged since its adoption a little over a year ago, the F. B. Stearns Company has just announced a six-cylinder Knight motor equipped car. The bore of the six-cylinder car is the same as the four, namely, 4.5 inches, while the stroke is .25 inch longer than that of the four, or 5.75 inches. This new Knight creation adheres to the design principles which have been so carefully worked out for the earlier type, in most respects. The front end of the motor is hung on an arched cross-piece, bolted to the side rails of the frame, replacing the aluminum arm construction usually employed. A separate cross-member supports the radiator. The rear end of the motor is bolted to the side members of the frame by integral crankcase arms. A four-speed gearset is used, while final drive is through a propeller shaft equipped with two universal joints. Gray & Davis lighting and starting systems are fitted as standard equipment on the sixes. The new chassis is made in two lengths having 134 and 140-inch wheelbases for which six body styles are provided. The 134-inch wheelbase

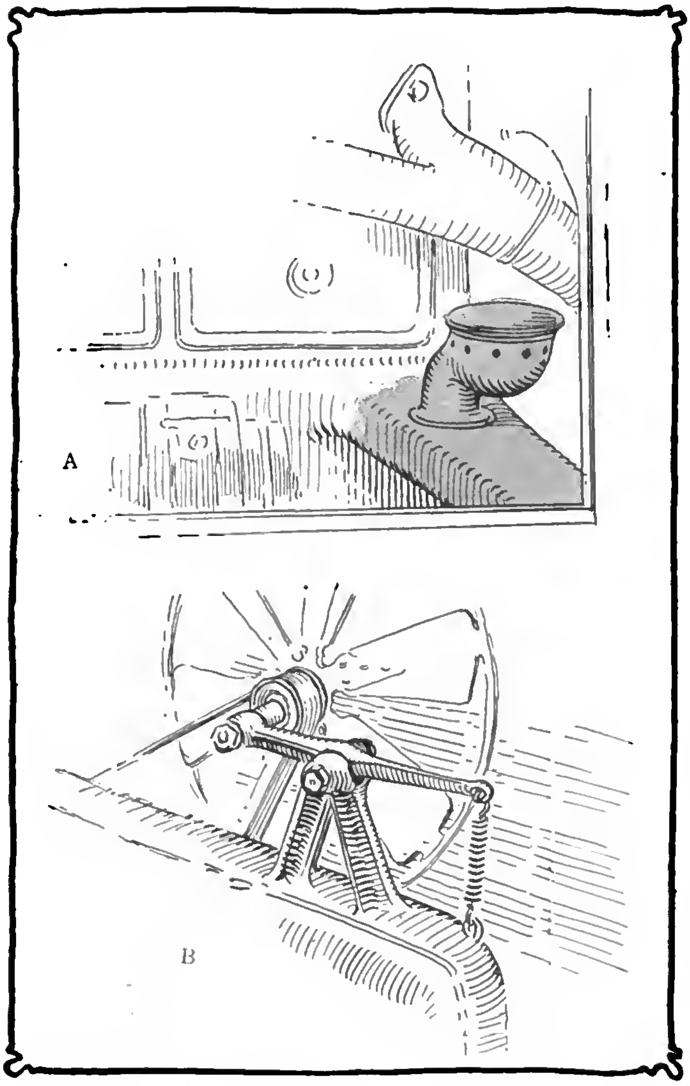

Fig. 24—A, Oil filler on S.G.V. cars; B, Spring tension on Velie fan belt

takes the three-passenger roadster, four-passenger light touring and five-passenger touring bodies, while the 140-inch wheelbase carries the seven-passenger touring type. Landaulet and limousine bodies are furnished for either chassis. The touring car bodies are all flush-sided with a narrow moulding around the bodies and doors. Running boards are clear, tires being carried at the rear on special brackets. Equipment is complete in every respect.

Stevens-Duryea—Only Sixes

Two six-cylinder chassis are made by the Stevens-Duryea Company for 1913. This is in line with the policy of this concern last year, but some minor refinements have been made. The motor is rated at 44.6 horsepower and has a bore of 4.3125 inches and a stroke of 5.5 inches. All types of bodies are fitted to this chassis. The Westlake dynamo will be incorporated on this year's cars, the valves will be inclosed, the oil leads will be inclosed, and one bolted-on valve cap will be placed over each exhaust and intake vave, one cap covering each pair of valves. The gravity feed gasoline is retained, but the running boards has been cleared. The tires are carried on the side. The starting system is by acetylene, the Prest-O-Lite tank being used in conjunction with a distributor of the Stevens-Duryea type. The wheelbases are 131 and 138 inches.

Stoddard-Dayton—Four Knights

Four models of Stoddard-Dayton cars will be produced by the United States Motor Car Company for the present season. The six-cylinder Knight car is, of course, the leader, while but one of the characteristic valve-in-the-head Stoddard-Dayton motors remains. Two smaller cars now use the L-head type of engine. Beginning with the sleeve-valve six, this car is fitted with left-hand drive and center control as last year's model was, and offers the option of wire wheels. Changes have been made in the design of the front axle, a new type of worm-and-sector steering gear is used, the radiator has been enlarged, new wheel-hub bearings have been fitted, and the control has been simplified. Model 48 is the only remaining model using the valve-in-the-head motor. It remains the same as last year in mechanical features, except for a few minor details which have been refined. The two L-head models 30 and 38 use engines cast en bloc with valve mechanisms inclosed, and show little deviation from former practices. All standard body types are fitted on each chassis with the exception of the 30, which takes a five-passenger touring, and a two-passenger roadster only. All body types have undergone refinement.

Studebaker—Adds a Six

Studebaker opens the season with three entirely new cars, two of them are four-cylinder types and the other is a six. Besides these three chassis, models 20 and 30 of last year are continued without radical change, making five distinct types now on the market. It will be remembered that the Flanders and E.M.F. cars are now given the name of Studebaker and that the model 20 referred to above was the Flanders 20, while the model 30 was the E.M.F. 30. Of particular interest are the three new models, which involve features new to Studebaker construction. A large number of parts are interchangeable on these three models. All the new motors of the L-head type with the cylinders cast en bloc and the valves on the left side. The exhaust and intake manifolds are cast integrally and so arranged that the gas enters the intake manifold on the side opposite the intake valves. The three models are known as the 25, 35 and 6. They all have the same stroke of 5 inches and models 25 and 6 have the same bore of 3.5 inches. The bore of the larger four-cylinder model is 4.125 inches. Three-bearing crankshafts are used in the four-cylinder cars and four-bearing crankshafts in the six-cylinder. The camshaft gears are of cast iron, while the crankshaft gear is of steel. A spiral pitch is used on these gears. The cams are integral with the camshaft as are also the oil-pump eccentrics. One feature of the new motors is the location of the water pump and magneto on brackets which bolt to the front end of the crankcase. The drive of these is accomplished by a transverse shaft driven by spiral gearing at its center from the crankshaft. Splash lubrication and Splitdorf dual ignition take care of these two important features, while starting and lighting is accomplished by the Wagner electric system. This system contains a motor-generator, geared 2.65 to 1, in relation to the crankshaft, furnishes the starting power and storing a six-cell, nine-plate storage battery of a capacity of 60 ampere-hours at a voltage of 12. The storage battery is placed on the left running board and the generator on the right side to maintain balance. On the 25 there is no starter, but an acetylene primer instead. The small car, model 25, has its driveshaft inclosed in a torque tube, but on the larger cars a stamped steel torque member is used. Three-speed gearsets are provided on all models, as is also the case with right control and drive.

Stutz—Puts Out a Sixes

In addition to the Stutz four-cylinder models a six is now on the market. Both have Esterline lighting and starting. It is of a similar design to the Stutz four-cylinder motors, but has a smaller bore and stroke, these dimensions being 4.25 by 5 inches. The Stutz four-cylinder motors, which are the same this year as last, have a bore of 4.75 inches and a stroke of 5.5 inches. It is of the T-head type with 2.5-inch valve. One of the added refinements this year is a hot waterjacket added to the intake manifold to warm the mixture before it enters the cylinders. In these motors the cylinders are offset .75 inch, and the connecting-rods are held at their big end by a four-bolt bearing cap giving a bearing 2 inches in diameter and 3.5 inches in length, The motors are lubricated by force feed through hollow crankshafts, the oil ducts being integral with the crankcase. Ignition system are the Splitdorf double distributer magneto on the four-cylinder roadster and the latest Eisemann magneto on all the other models. Exactly the same bodies are used on the four and six-cylinder models. The four-cylinder touring and the six roadster have a wheelbase of 120 inches, while all other bodies are put on a 124-inch wheelbase chassis. The six has a 130-inch wheelbase for the touring body. Some changes have been made in the Stutz rear system, although the general design is the same as has been used for the past 5 years, the differential case being about 2 inches larger in diameter. An outside adjustment has also been provided for adjusting the mesh between the drive pinion and the bevel gear. By removing two small plates on either side of the differential case an adjusting collar can be reached to move the drive gear in either direction. Right drive and control with inside levers are used on all models.

Spaulding—Drops Small Model

In the third year of motor car manufacture the Spaulding Manufacturing Company, Grinnell, Ia., has made additions to its plant, and expects to greatly increase its production for 1913. The Spaulding is designed along recognized and conservative lines, and has been little modified in its 1913 model. The small model has been dropped and the large one continued. The principal changes that have been made are the installation of the Gray & Davis electric lighting and starting system; an electric heating system; left-hand drive with center control; demountable rims with a spare; a tire holder in the rear, and modifications in the motor size. The motor has been changed from 4.125 x 5.25 to 4.25 x 5.5. Modifications are to be noticed in the oiling system; the valve-mechanisms have been inclosed; and the intake manifold is not cast integral with the cylinders, which are this year en bloc, instead of separate. A pressed-steel rear axle of the floating type is used. The wheelbase is 120 inches, and the tires are 36 by 4 instead of the corresponding dimensions of 117 and 34 inches of last year.

Velie—Adds New Four

In addition to the model 40 the Velie Dispatch has been put on the market. This is a new motor incorporating a large stroke bore ratio, the cylinder dimensions being 3.75 by 5.5 inches. The motor is rated at 32 horsepower at 1,000 revolutions. The cylinders are cast en bloc and many other features common to modern cars are involved. Among these may be mentioned silent chain drive for magneto and camshaft; enclosed valves and thermo-syphon cooling. The crankshaft is carried on three main bearings and has a diameter of 3.25 inches. The valves have a clear diameter of 7.125 inches. Among the other chassis features on this model are left drive and center control. A floating axle carried on roller bearings is also incorporated. The Velie 40, which is continued, has a bore of 4.5 inches, and a stroke of 5.25 inches. The makers claim that it develops 40 horsepower of 1,000 revolutions per minute and 50 horsepower at 1,600 revolutions per minute. A 1.25-inch double jet Stromberg carbureter is used on this model, while the ignition includes a Splitdorf high-tension magneto, and an Atwater Kent unit sparker. The clutch is a three-disk drive-plate type, fitted with an automatic clutch brake. The dynamo electric lighting system with five lamps and a Disko starter are included in the Velie equipment.

Winton—Changes Springs

Three-quarter elliptic rear springs, suspended outside the frame rails, are the chief point of difference between the Winton car of 1913 and its predecessors. Otherwise the current line presents small variation from last year's cars. The cowl is given a trifle less angle and the doors have been trimmed slightly with handles placed inside the body. Ventilation has been improved in minor details. The change in springs gives the opportunity to curve down the rear of the body without a break, which has been done with pleasing effect. Trifling changes have been made in the upholstering, designed to augment riding comfort.

White—Three Models

Monoblock castings and long stroke are characteristics of White gasoline productions. The leader of the line is the White six cylinder which is now in its second season, having been shown first in 1912. Embodying many refinements, this model, with the 30 and 40 of last year, has been continued on the series production plan. The new 30 has been redesigned with left-side drive and center control the same as the six and the 40. The current models are in the order mentioned, models GF, GAF and GEB. The six model has its six cylinders in a single casting, all valves on the right side with inclosed mechanisms and 4.25 by 5.75-inch bore and stroke. Three ball bearings are used as engine journals and both manifolds are integral with the cylinders. This, with conduited wires and concealed water passages, imparts a pleasing, clean appearance to the motor. Two fans are used in connection with the pump-circulated water-cooling system, one of which is behind the radiator and the other the vaned flywheel. A carbureter of White design is used, and a compression-relief is fitted for starting. The electric starter is a part of the White electric lighting and starting system, which is of the single-unit type, the dynamo fulfilling both the functions of a motor and a generator for charging the battery. This system is used on all models. General chassis details on the six differ only in dimensions from the other models. Body types include touring cars, roadsters, limousines and Berline limousines and coupés.

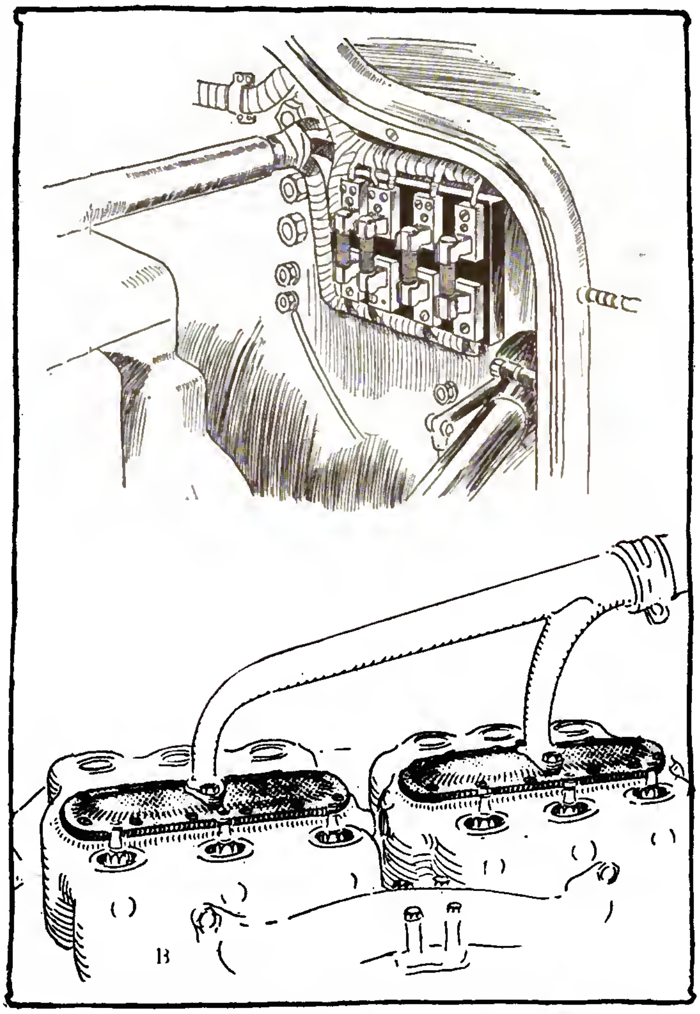

Fig. 25—A, Fuse box of White dash; B, Jacket plates on Touraine six

*Underslung Frame. †Has six wheels.

ABBREVIATIONS:—Model: Tour, touring; Road, roadster. **Cylinders:** Sep'rt, separate. **Valve Location:** Opp, valves on opposite sides of cylinder; Head, both valves in head; L & H, left side and in head; R & H, right side and in head. **Camshaft Drive:** Gear, spur gears; Hel'l, helical gears; Spi'l, spiral gears. **Cooling Circulation:** Thermo, thermo-syphon. **Radiator:** Cell, cellular; Tub, tubular. **Lubrication:** Spl-Pres, combined splash and pressure system in circulating unless called Noncir. **Ignition:** Sing single; Doub, double; Dual 2, double distributer; Gov, governor; Atw Kent, Atwater Kent. **Fuel Feed:** Grav, gravity; Pres, pressure. **Engine Starter:** Spr, spring; Elec, electric; Acet, acetlyene; Mech, mechanical; Opt, optional; Air, compressed air. **Bore and Stroke:** In decimals to nearest 1-100 inch, as 4.25=$4\frac{1}{4}$, etc., .06=$\frac{1}{16}$, .19=$\frac{3}{16}$, .13=$\frac{1}{8}$, .25=$\frac{1}{4}$, .31$\frac{5}{16}$=, .38=$\frac{3}{8}$, .44=$\frac{7}{16}$, .5=$\frac{1}{2}$, .56=$\frac{9}{16}$, .63=$\frac{5}{8}$, .69=$\frac{11}{16}$, .75=$\frac{3}{4}$, .81=$\frac{13}{16}$, .88=$\frac{7}{8}$.

Horsepower and Mechanical Details

In Calculating the Horsepower of the Motors Given in the Table the S. A. E. Formula Was Followed—That Is, Horsepower Equals Cylinder Bore Squared, Multiplied by the Number of Cylinders Divided by 2.5.

Tendencies in Regard to Piston Displacement Among the American Automobile Manufacturers for 1913

Looking back over the last 3 years, there is a decided trend on the part of manufacturers who continue the same model over this period, to increase the amount of the piston displacement. This is graphically shown in Fig. —. With the exception of a few cases where the piston displacement has remained the same, this table shows that it is general practice to make the same model for 2 years and then to increase the motor size, or to have increased the size in 1912 over that of 1911 and leaving the 1913 models the same as 1912.

In many cases this increase can be directly traced to the practice now prevalent in lengthening the stroke. An example of this can be found by referring to the table on page — wherein comparisons of twenty various makes of cars are shown in their different models for the last 2 years, including 1913. The Model 32 Peerless in 1911 had a bore and stroke of 5 and 5.5-inches respectively giving a piston displacement of 647.9 cubic inches. In 1912 the stroke was increased to 7 inches, leaving the bore at 5 inches. This increase in stroke gives 174.9 cubic inches more piston displacement and this size is being continued for 1913, the total piston displacement of the engine with the increased stroke being 824.8 cubic inches.

Another example is the 1913 Cadillac, in which the stroke of the motor has been increased from 4.50 inches to 5.75 inces, the bore remaining 4.50-inches as heretofore. This increase of 1.5 inches in the stroke corresponds to an increase of 79.5 cubic inches piston displacement.

In drawing comparisons among the various models, the question of bore has been the main point upon which the similarity between the model of one

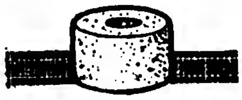
Together with a Brief Résumé of the Changes Made by the Various Companies for the New Season

year and that nf another have been compared, aa this shows how the modela nf the same rated horsepower have varied nver the period uoder review. In this connection the ease nf the Locomobile reveals how dealing with bore alnne is liable to be very misleading. In 1911 and 1912 this make of car was offered, amnng other models, with a six-cylinder motor, having a bore and stroke of 4.50 inches, in other words, a sqnarc engine. The piston displacement of tbis engine was 429.5 cobic inches. In 1913, apart from any structural alterations, the bore was retained as before at 4.50 inches, while the stroke was increased to 5.50 loches, bringing the pistnn displacement np tn 524.8 cubic inches. A new model has been added with a bore and stroke nf 4.25 and 5 inches, giving a piston displacement nf 425.4 cnbic inches nr 4.1 cubic incbes less than the 4.50-inch sqosre enginc of 1911.

Several concerns such aa the Packard, Chalmers, Haynes, Franklin and Stearns whn brooght nnt new models for last season, have retained them in exactly the samc sizes for 1913, which bears out what has already been stated, namely, that in most cases the same size engine is marketed for 2 years without alteration as to piston displacement. The Packard models are now all six-cylinder designs, and while it might not be correct to contrast a six agaiost a fnnr, nevertheless a comparison nf pistnn displacement shows that the new six-cylinder is smaller than the largest fnnr previously manufactured. Reference to tbe table shows that while it is not moch smaller than the large four-cylinder motor nf last year, it is considerably larger than the 18 which was the smaller model. The displacement nf the fonr-cylinder 40 Premier for last year was 884.0 enbic inches, while the new six-cylinder type has a displacement of 376.9 cubic loches nr 42.9 cubie inches mnre than the preceding four cylinder.

The Carbureters for 1913

Many Companies Add New Models—Multi-jet Design Makes Steady Gains—Various Devices Attached to Facilitate Starting—Several European Products Now on the Market—Absence of Moving Parts a Pronounced Foreign Trend—Auxiliary Air Valve Continues in Popularity in America.



THAT the season of 1912 was an active one in carbureter research and invention is proven by the changes in many of the standard models as compared with their predecessors and also by the number of new models listed for this year, not a few of these being introduced by the largest makers. The heavier weight of gasoline used has been largely responsible for much of the carbureter activity, and coupled with this is the demand for extreme motor flexibility over an ever-increasing range of speeds.

The keen rivalry among the carbureter makers has played its part in this work of evolution, and while there is much that is new to be seen at the shows, there is also more behind the screens. One or two of the makers have announced that they have ready to show to the engineers new models which they are not going to announce to the public for some time.

To summarize whither the tide of carburetion is flowing is somewhat difficult, but in a sentence, it is leading in the direction of multi-jets and the reduction of moving parts, this conclusion being reached by a survey of the score or more of American carbureters, and also from the dozen European types that are now on the American market. Schebler has joined the multi-jet ranks with a new model, O, fitted with main and supplementary jets; Stromberg in its new models uses two jets, although this concern has used the double-jet idea in one of its models for several seasons; and Pierce in its new carbureter, which it makes for its own product, has added a supplementary jet. More could be cited. Up to the present the single-jet type is practically a 75 per cent. leader over the multi type.

There are various reasons which indicate the direction in which the wind is blowing when it comes to the reduction of moving parts, although at this date it is quite beyond the realm of speculation as to what the eventual type will be, and it is more than probable that the time will not arrive for years when any one type will be the adopted standard, because most satisfactory results can be had with different types.

In Europe the situation to-day is more defined. R. W. A. Brewer in writing on the subject to THE AUTOMOBILE, at the close of the recent Olympia show, said: "I think I am perfectly correct in saying that there was not a single European car at the Olympia fitted with any sort of extra-air-inlet device; the general tendency seems to be in the direction of a combination of jets or some type of varying jet orifice."

Very pronounced progress has been made in American carbureters in the fitting of easy-starting arangements. This movement started 2 years ago with the fitting of shutter valves to obstruct the normal air passage in order to increase the motor suction or pull on the gasoline in the spraying nozzle and thereby obtain a very rich mixture. At that time a few of the leading carbureter engineers fitted an interconnection between this shutter valve and the auxiliary air valve so that the latter could also be held shut when the shutter valve was closed. Today these concerns are going a step further and are fitting what may best be termed a gasoline by-pass pipe which connects direct between the float chamber or the nozzle and the intake manifold above the throttle; the modus operandi being that to start, the throttle can be practically closed so that the entire motor suction is on the upper end of the by-pass tube, this suction being sufficient to draw the pure gasoline through, giving the necessary richness. The different ways in which these starting by-passes are fitted are shown in the different illustrations which follow.

A problem in carburetion is to maintain a requisite suction or pulling force on the gasoline in the nozzle at the different motor speeds, so that the mixture will be of the desired composition, having the proper proportion of air and gasoline. There are many difficulties in this job. For example: At low speeds a richer mixture may be needed, and if enough gasoline is issuing from the nozzle there will be too much flowing when the motor speeds up and the pull or suction of the air passing the nozzle has increased in direct proportion with the increase in motor speed. To relieve such a situation means must be provided to keep the suction down and, instead of giving a mixture richer in gasoline at high speeds, give a mixture that is leaner.

There are several ways of establishing the desired balance at the nozzle. The oldest and best known method in America is by the auxiliary air valve. It operates as follows: All of the air enters the air passage surrounding the nozzle up to predetermined motor speeds, but when the motor speed increases the auxiliary valve opens and allows air to enter, which has not to pass the nozzle, but preferably enters the mixing chamber at a point higher up. The entrance of this air naturally cuts down the velocity of the main air supply entering around the nozzle, and so, with its velocity reduced, there is a corresponding reduction in the amount of gasoline issuing.

A second class of makers, who are apparently opposed to the spring or dashpot-regulated auxiliary air valve, uses what may be designated a variable venturi, the venturi being the hourglass air passage in which the nozzle is located. The object gained by increasing the cross-section area of this passage on high speeds is identical with that in the auxiliary air valve, in that with the cross area increased the velocity of the air to the motor is kept constant and so the pull on the fuel in the nozzle is kept down. There are various ways of accomplishing this; one does it by a plunger piston which is controlled by the motor suction and which piston partially obstructs the air passage; another does it by a series of varying-diameter ring valves, and a third accomplishes it in a different manner.

There is a third class that uses neither the auxiliary air valve nor the variable air passage, but, on the other hand, regulate the suction by atmospheric pressure, this type of carbureter generally being one without moving parts.

There is a fourth class that aims to control this nozzle suction by mechanical means Generally a moving needle is fitted in the tip of the nozzle. This needle is interconnected with the throttle, and as the throttle is opened the needle is raised only in proportion as additional gasoline is needed. Then, too, there are some who use the moving needle in the nozzle, and also use the auxiliary valve in combination with it.

In the following pages the leading types of various carbureters now before the American buying public are briefly described, without any attempt being made to opinionate on their respective merits, a task left to the reader. Vertical-section illustrations, made from blue prints, are used wherever possible to show the principle on which the different types operate. The modus operandi of each is explained.

Schebler—Introduces Multi-Jet

There is a new Schebler carbureter for this year. Its official name is model O and it differs from all previous Schebler models in that it uses two spraying nozzles or jets, one known as the main jet C, is located in the venturi-shaped air passage which is concentric with the float and the other or secondary jet D is mounted higher up in the carbureter wall. This secondary jet is under the control of a plunger valve, which is raised from its seating by motor suction and permits the flow of gasoline past it. The main jet with the venturi forms the low-speed feature of the carbureter and performs all of the functions up to motor speeds of 400 revolutions per minute. Above this speed, the suction at the jet is reduced by the admission of extra air through a spring-regulated auxiliary air valve A. This auxiliary air valve governs the mixture between the range of 400 and 800 revolutions per minute. Above the latter figure the auxiliary jet D comes into play. The suction at this point lifts a small poppet valve at D, closing what may be called the auxiliary mixing chamber, and allows a mixture of gasoline and air to join the mixture secured from the jet in the venturi. The auxiliary jet is formed by the space left between the small poppet valve and its seating when the former is raised by the suction against the spiral spring holding it in place and by a tube which carries the gasoline from the float chamber to the auxiliary mixing chamber. The air for the auxiliary mixing chamber enters through a port in the casting, leading to the outside air. This carbureter is supplied with a hot-water jacket and with an easy starting shutter, which is operated by a bell-crank lever which closes by means of a butterfly valve B, in the main air inlet and locks the auxiliary air inlet through an inter-connection. The carbureter has three adjustment points; one, the needle valve which determines the size of the main jet; and the other, a knurled screw which determines the tension on the spring controlling the poppet valve for the secondary jet.

The Schebler L, Fig. 2, has been improved over the 1912 style. It operates on the same principle as the model O, but has but one jet. The suction at this jet is determined and governed by a spring-regulated auxiliary air valve V. This carbureter is provided with a modified Venturi mixing chamber B, the smallest section of which is at L, the point where the fuel is sprayed from the nozzle N. The needle valve regulates the flow of gasoline through X and from the supply source. The auxiliary air valve is regulated by an adjustment screw which varies the tension in the conically wound spring. This spring acts against the suction of the motor, and the greater the speed of the latter, and hence the greater the suction, the more the auxiliary air is admitted due to the increased opening of this air valve, which is also provided with dash control through the rack and pinion shown.

In operation, the main air supply enters vertically through the main air passage, mixing with the atomized fuel at L. The needle valve may be externally adjusted by means of a thumbscrew. The nozzle extends diagonally into the mixing chamber and is provided with a long tapering needle which admits of fine adjustment. There are means of regulating fuel supply and air supply relative to one another externally by dials playing over graduated scales and thus indicating the proportions of the mixture ingredients. This type is waterjacketed around the outlet passage to the manifold. A spring pin provided with a bell-crank lever also makes it possible to depress the float, thus raising the needle valve and flooding the carbureter when necessary. A very good feature of this construction is the provision for the removal of the entire float chamber, float and its needle-valve mechanism. A single nut working on the threaded lower por-

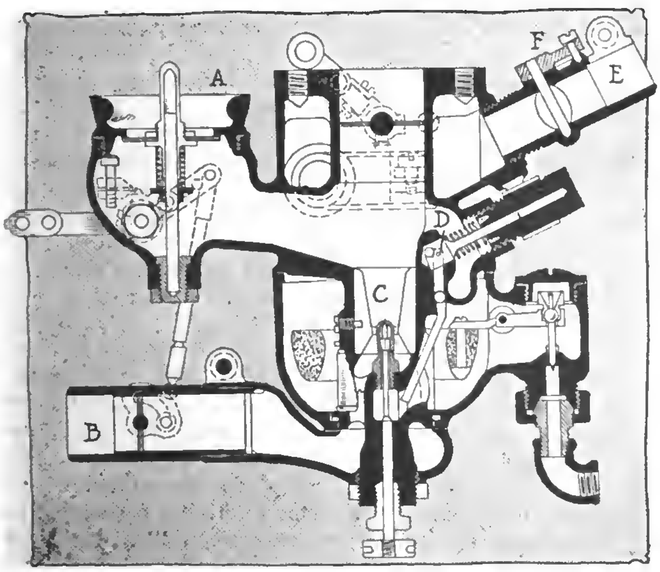


Fig. 1—Schebler O has a poppet shaped secondary jet

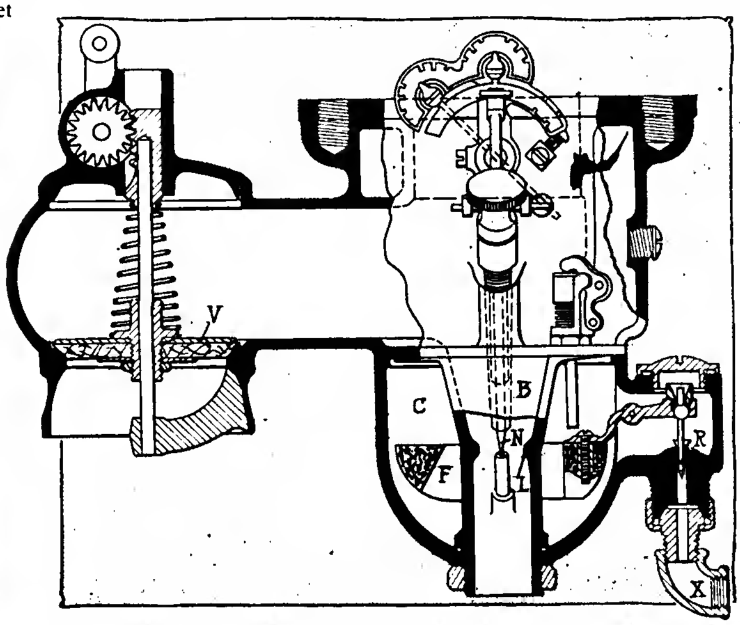

Fig. 2—Schebler L has concentric float and spring auxiliary valve

tion of the main air inlet tube holds the fuel chamber in place, and for cleaning purposes this accessibility feature should prove of great value.

The other Schebler models are continued as during 1912.

Stromberg—Two New Multi-jet Models

To the three Stromberg carbureter models of last year have been added two new models which, while built along general Stromberg lines, incorporate some new features by way of improvements.

The three models of last year, A, B and C, have all been improved in that they are fitted with a new funnel-shaped venturi tube in the center of which is located the main nozzle. This venturi threads into the body of the carbureter. Of these models, A and B are single-jet types and C is a double-jet design. B has a concentric-float construction for small motors, while A and C are not concentric designs.

Of the new models, G is quite similar to model A, Fig. 5, excepting that it is made without a waterjacket. It is also a double-jet type, the supplementary jet being located in the horizontal passage between the mixing chamber and the auxiliary air valve. This jet has an adjustable needle-valve regulation. The venturi is threaded into the carbureter body and this part is so grooved that an opening extends around the venturi. The side of this opening towards the float chamber opens through the main body of the carbureter to the atmosphere and the other side opens in the gasoline tube leading to the auxiliary nozzle at a point above the gasoline level. Its operation is as follows: Low speeds are supplied by the primary nozzle in the venturi; as the motor speed increases, the suction on the auxiliary gasoline nozzle also increases, but no gasoline issues from this nozzle until the suction of the motor on it becomes greater than the capacity of the bleeder hole connecting with the atmosphere through the groove around the venturi. After this point is reached, gasoline flows through the supplementary nozzle, its flow increasing or decreasing with the motor speed.

Model D, the other newcomer, Fig. 4, is a two-jet type with the auxiliary nozzle I located in the passage between the mixing chamber and the auxiliary air valve and controlled by the latter so that the needle K controlling the nozzle is raised when the auxiliary air valve opens. The air valve is a new design of balanced construction and works in a chamber surrounded by a sleeve which can be operated from the dash. This sleeve fixes the size of the air opening for the valve. The hollow valve stem

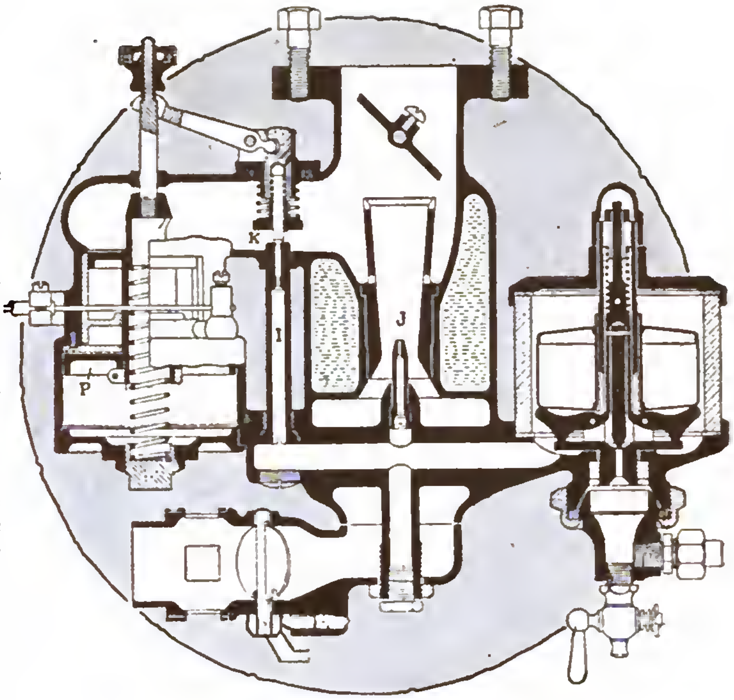

Fig. 4—Stromberg new double jet with eccentric float

carries two pistons operating in a dashpot, so as to give a richer or leaner mixture from the auxiliary jet, depending on whether the sleeve-controlled air opening is exposed to a lesser or greater extent. No adjustments are required with this carbureter, save for the use of the correct size of main nozzle and auxiliary-jet needle, a variety of sizes being provided by the manufacturer.

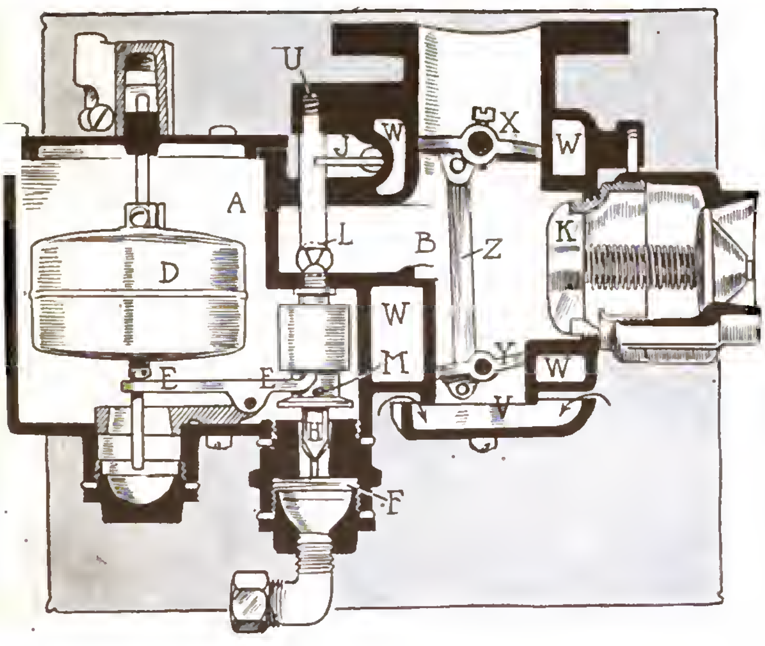

Fig. 3—Rayfield model D carbureter with interconnected throttle and air

Rayfield—Continues Mechanical Type

The Rayfield carbureter, Fig. 3, belongs to that class in which the flow of gasoline from a single nozzle is controlled by a needle valve interconnected with the throttle, so that with wider throttle opening there is a wider opening in the nozzle. But this interconnection with the throttle goes further in that the main air entrance is controlled by a butterfly Y linked to the throttle X, thereby regulating the primary air supply, according to the throttle position. There is also an auxiliary air valve K under spring regulation. The variable needle valve L is held seated by the spring U and is operated by the arm J. It is interconnected with the throttle and air shutter X and Y, these two valves being linked together by the bar Z. These valves have provision for adjustment so that they may be so operated relative to each other that the proper proportions of air and fuel are combined in the mixing chamber B. The auxiliary air valve K is so adjusted as to open under the greater suction of high speeds and to allow the entrance of the needed air for such increased speeds. The stationary air intakes are seen at V and back of the needle valve, L, opening ino the mixing chamber, as shown. Referring to air valves X and Y it will be noticed that butterfly throttle has a slight lead on the valve Y. This provides for slow running with closed or very low throttle, allowing just enough air to pass in proportion to the very small nozzle opening.

The Rayfield reveals standard float construction so far as the float mechanism is concerned, in that the float D is of metal playing in the float chamber A, and connecting with the inlet needle valve through the pivoted lever E. As the fuel enters from the supply source it is strained through the screen F before passing through the needle valve. Admission to the mixing chamber is through the center of the nozzle, which is opened and closed by the needle L. The lower end of this nozzle which communicates with the float chamber is provided with several radial holes M running to the hollow center. The gasoline enters

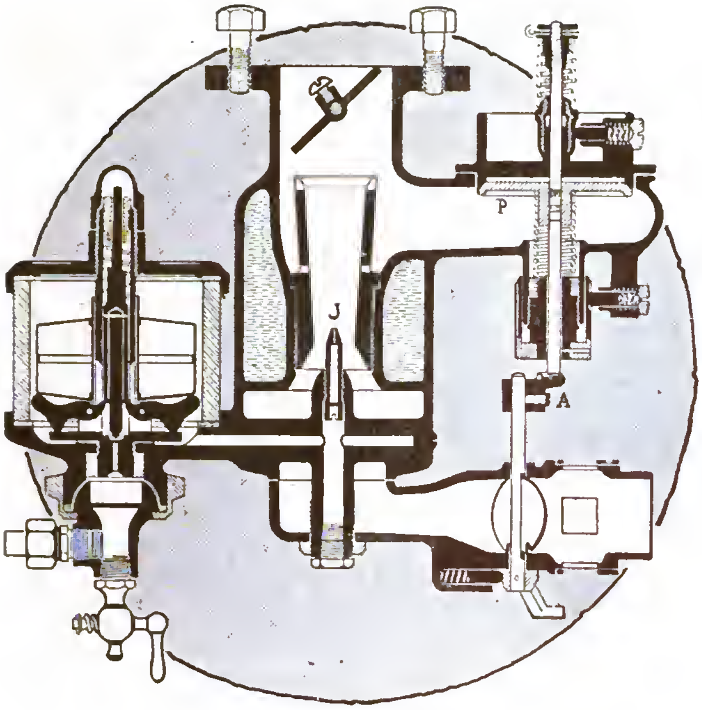

Fig. 5—Stromberg single jet model with eccentric float feed

these holes and thence flows up through the nozzle to its orifice.

Waterjacketing is extensive, the mixing chamber being fully covered where possible, as shown at W. A dam at the point where the fuel passage merges with the air chamber allows for the collection of a small amount of gasoline when the engine is not running. When started, this pure fuel is drawn directly into the motor, priming it in the usual way.

It should be especially noted in a consideration of the Rayfield instrument that the mixing is entirely automatic, no suction or vacuum principle being utilized to regulate the amount of fuel supplied, this being mechanically apportioned by the driver when he opens the throttle. Such an instrument must be adjusted for every variable, there being four points for regulation. However, when these are properly related the instrument has proven remarkably efficient. This carbureter was used on the winning Mercedes in the 1912 Vanderbilt and Elgin races.

Zenith—Without Moving Parts

There are in the Zenith carbureter, Fig. 6, three jets. Two of them are concentric, namely, G and H, and the third one is on the same level as the butterfly throttle valve at U. The outer annular jet H is connected at its lower end with the tube E, this tube being fed by a small orifice from the float chamber. The supply of petrol into this tube is constant for it depends merely upon the height of the petrol in the float chamber; thus the supply of gasoline to the annular jet does not increase when the engine suction increases; indeed this supply actually decreases for the jet is starved owing to an insufficient supply into the small tube E.

The action of the main jet G is similar to that of ordinary single-jet carbureters, so that it is of course possible to make it of such a size as to give the best results for a given speed. It is, however, patent that should this given speed be increased, or not reached, then the mixture will become too strong or too weak respectively. It is in this fact that the *raison d'être* of the subsidiary jet is to be found, and it will be seen that it is possible to strike the happy medium by drawing the necessary quantity of petrol from two jets which operate in diametrically opposite directions. As the speed of the engine increases, more and more gasoline is drawn by the suction from the main jet in direct proportion to the progressive diminution of the quantity of petrol per revolution of the other jet.

So much for the two main jets. Now a few remarks with reference to the small throttle jet situated at the upper end of the tube J; this tube which is for the purpose of adjusting for slow running is open at both ends and fits closely into a well. On the left-hand side of this well is cut a vertical groove terminating at U. On the lower portion of the tube O is cut a partial helix which coincides with the aforesaid vertical groove. It will thus be understood that by rotating the tube J by means of a milled screw the point of contact between the vertical groove and the helix will be raised or lowered according to which way the tube is rotated. Thus, if the point of contact be low, more petrol can be sucked through U, while if the point be raised the mixture becomes weaker. By this means the slow running of the engine can be adjusted from the exterior by rotating the small screw B, which is fixed to the tube. When the desired running has been obtained, the screw is tightened to permanently set the position.

Under ordinary running conditions the tube J does not come into action, the two jets providing all the petrol that is necessary. It is principally under starting and slow running conditions that this part of the carbureter comes into play. In order to start the engine the throttle is only opened very slightly, and on turning the engine over by hand, a very strong suction is set up at U, which draws the petrol through the vertical groove and out through U, where it is vaporized by the inrushing air. By this means, at the first turn of the crank, a quantity of suitable mixture is induced into the cylinder, causing the engine to start immediately.

When an engine is throttled down to run very slowly, out of gear, the depression around the concentric jets is extremely weak and not sufficient to draw petrol from them. The petrol will then rise in the tube J until it reaches the point of contact when it will be strongly sucked up and sprayed at U, thus providing the exact quantity of mixture necessary to keep the engine turning over slowly out of gear.

The carbureter is a simple one and its modus operandi is extremely ingenious especially the details connected with the tube U. The later models have a small glass window in the float chamber through which it is possible to at any time observe the level of the gasoline in the float chamber. This window is not, however, shown in the diagram.

Holley—1912 Type Continued

The Holley is a good example of the concentric-float type of carbureter in which the main air passage, Fig. 7, does not rise

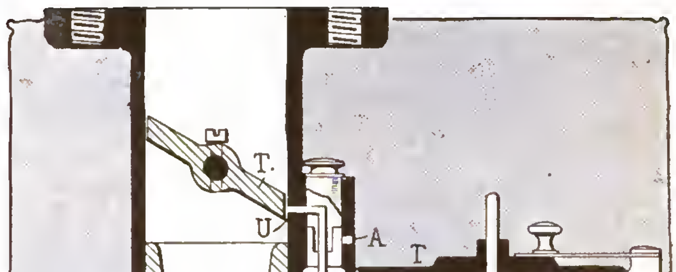

Fig. 6—Zenith carbureter employs auxiliary jet at butterfly valve edge

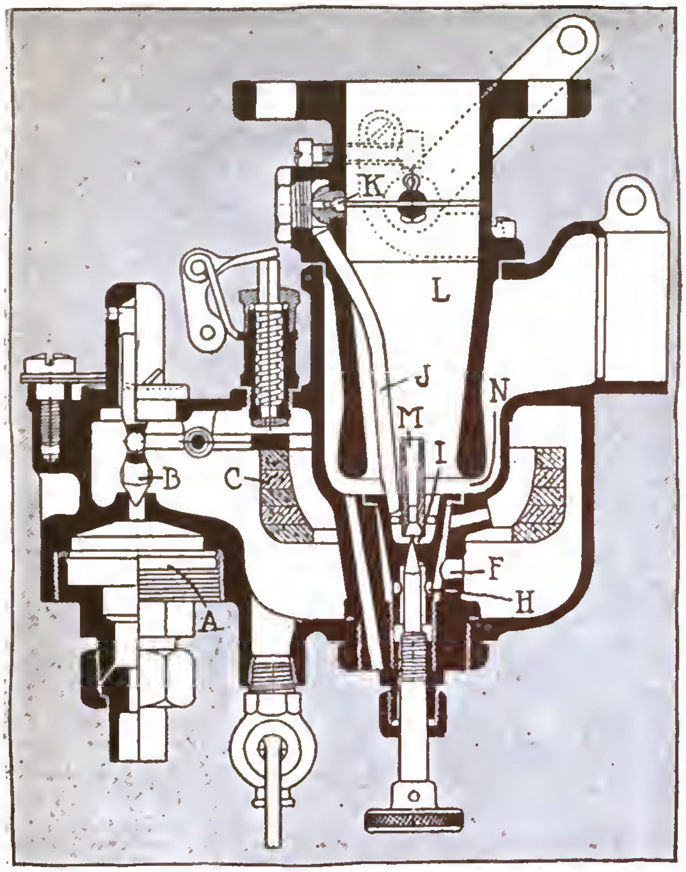

Fig. 7—Holly carbureter has concentric float with adjustable jet

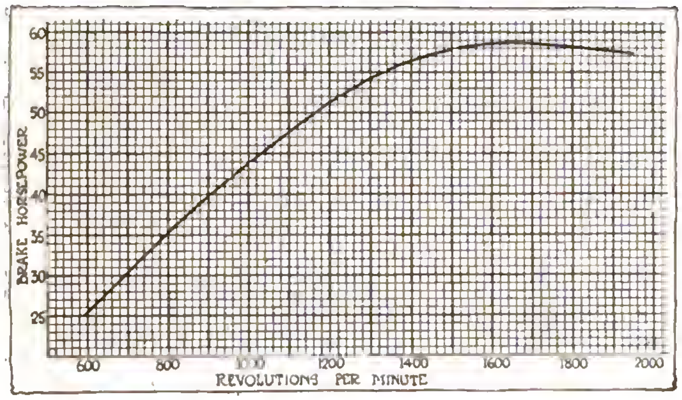

Fig. 8—Steady rise in horsepower curve of six-cylinder motor with 4.125 x 5.25-inch cylinders. Zenith carbureter

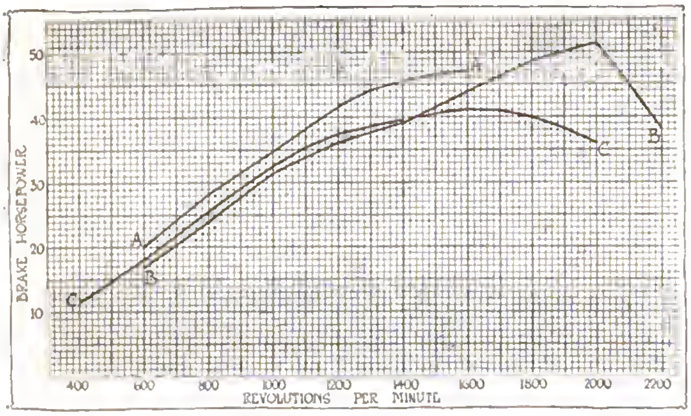

Fig. 9—Horsepower curves, Schebler L, carbureter. A, L-head four cylinder 4.5 x 5.25; B, valve in sides 3.8125 x 5; C, L-head 4.125 x 5.25

vertically from the base of the instrument, but through the side, at a point above the level of the float chamber, being deflected downwards by a venturi-shaped mixing chamber, the passage of the air being indicated at N.

In this type the entire air supply passes the spray nozzle. The cork float mechanism C is conventional, and fuel enters the float chamber through the needle valve B, after having passed through the strainer disk A. It passes from the float chamber through the opening F drilled through the wall separating the nozzle well and the float chamber. From this nozzle well E the fuel entered the nozzle proper through the holes H, rising past the needle valve I and lodging in the cup-shaped upper end, just submerging the lower end of the tube J, which extends to the edge of the throttle disk controlling the supply of fuel to the engine. Cranking the latter with the throttle nearly closed draws the fuel from the well through tube J and the calibrated plug K, and directly to the manifold, thus priming the motor and acting as an easy starting feature. After the engine is running the fuel sprays through the needle valve and up through the tube M, and thence directly on to the motor through L. When thus running, air is drawn through the holes N surrounding the standpipe M and part is drawn up through the tube J, keeping the starting well completely cleaned out.

It will be seen that there are no spring-controlled air valves, the suction being depended upon for control of the air supply. The standpipe M has a venturi shape, aiding in the fuel vaporization. The carbureter has only one adjustment, that being of the needle valve I. The principal feature of note in the carbureter is the utilization in the nozzle action of the pressure drop due to the velocity of the flow of air drawn through, rather than the pressure drop causing the air to flow, making the carbureter automatic in its proportioning functions. Having fixed the needle valve adjustment, the ratio of air to gasoline must be constant throughout the range of engine speeds.

Kingston—Uses Ball-Type Air Valve

The Kingston carbureter, a concentric-float design, continues to use a series of metal balls forming the auxiliary air supply, but has modified the general appearance in that the needle valve D, which controls the supply of fuel through the nozzle, is mounted at an angle, and has the usual external adjustment. In this carbureter the requisite vacuum at the nozzle is maintained through the medium of the auxiliary air valve. The weight of the balls constituting this valve being so regulated that they are lifted in rotation to supply the requisite demands of the energy.

The fuel is sprayed into the mixing chamber at E, where it comes in contact with the main air supply entering at F, the mixture passing on to the motor in proportion to the opening of the throttle G and through H. With greater engine suction the auxiliary ball-check valves come into operation, being raised from their seats and admitting additional air to the mixture. These opening areas are so arranged that the effect produced is similar to the action of an automatic expanding venturi.

This Kingston design includes a special provision for easy starting, in addition to the choke throttle placed in the air inlet at J, which, when closed, produces a very strong suction or vacuum at the spray nozzle drawing a very rich mixture.

The well K around the nozzle fills partially when the engine is not running, due to the greater height of the gasoline level in the float chamber C. This gives a reserve supply of fuel which is directly drawn through the inlet H to the motor, priming it on the first few suction strokes. After the engine is running the fuel is drawn swiftly through this well and there is no opportunity for it to collect here as long as the engine produces the vacuum around the nozzle.

Stewart—Has Floating Control

This Stewart precision is a concentric carbureter of the constant-suction type and the main working element consists of a vertical cylinder gunmetal valve E supported in the air stream and provided with a small tube dipping into the float chamber, its upper end being level with the top of the valve. The illustration Fig. 12 shows the valve E off its seat as it is when in operation. Along the upper end of the tube is an annulus communicating by way of a series of holes with the lower or atmospheric side of the valve and the air passes through the valve head up the annulus drawing gasoline up the center tube T. The main hole through the valve head is .375 inch diameter, while the inside diameter of the gasoline tube is .125 inch. The small tube reaches down into a gasoline well and formed within the valve stem, and the valve stem is provided with a lower extension tube H which regulates the supply of fuel to the engine. When the floating valve E is upon its seat, sufficient air passes through tubes C and by way of holes R admitting air from below. This air is concentrated round the orifice of the central tube, thus providing a suction effect sufficient for starting purposes. Increased suction effect lifts the valve E to a greater extent and slides the small tube surrounding the needle P; this needle is tapered so that the sliding up and down of the tube varies the size of the annulus formed by the tube and needle and this varies the quantity of gasoline passing into the chamber O. In its seated position the lower tube H seats around the metering pin P, but with sufficient clearance so that enough fuel can pass for starting purposes. In the lower part of the instrument there is a dashpot to prevent the too rapid movement of the valve E. The cork-hinged float and its valve need little description. After the motor is cranked the vacuum increases, the valve E lifts from its seat, allowing additional fuel to pass the regulating pin P in proportion to the suction. This raising of E also allows a proportionate quantity of air to pass through V to combine with the additional fuel. Thus in running, the valve E is held up an amount in proportion to the vacuum created by the demands of the motor and is entirely automatic except insofar as the regulating pin must be adjusted.

Flechter—Single or Multi-Jet

The Fletcher carbureter is made in either single or double-jet types, the latter being for use in larger cars. The carbureter is of the concentric float type with a fixed jet working within a modified venturi. The additional air supply for intermediate and high speeds is furnished by an auxiliary air valve. In models above the 1.25-inch size the auxiliary air valve is controlled by a piston and dashpot arrangement which prevents chattering, below this size the auxiliary air valve is controlled by a spring. The main fixed jet within the venturi and the air which enters the venturi passage from the lower extremity take care

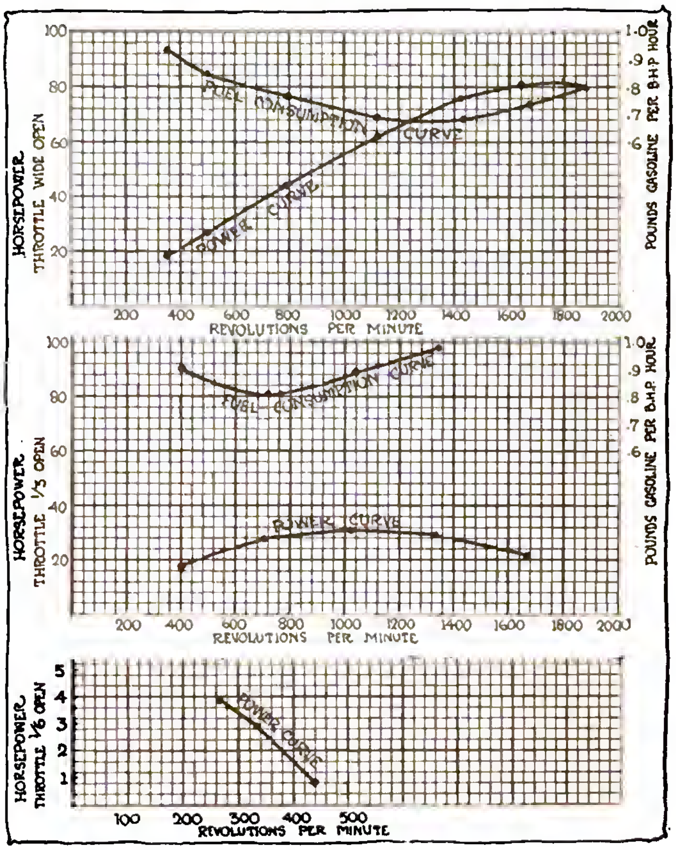

Fig. 11—Horsepower curves with different throttle openings using Newcomb carbureter. In each case A is the power curve and B the fuel consumption curve. These curves are plotted on a basis of revolutions per minute and in the case of the fuel consumption read in pounds of gasoline. There are roughly 6 pounds to a gallon of gasoline

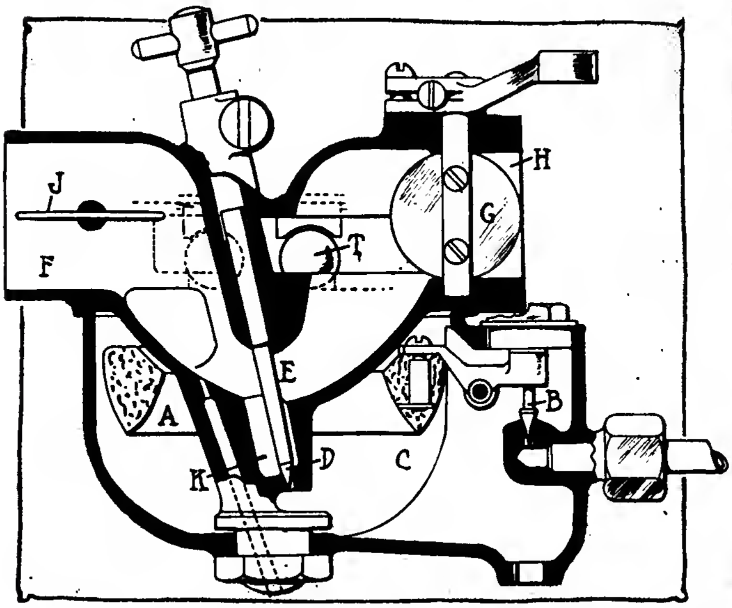

Fig. 10—Kingston carbureter uses concentric float and ball auxiliary air valves

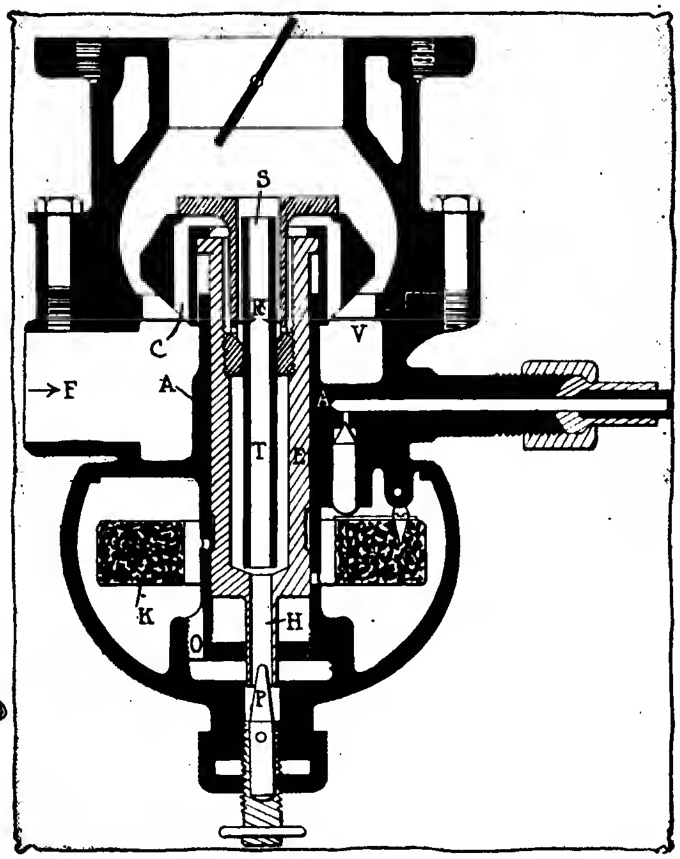

Fig. 12—Stewart precision multiple concentric jet carbureter one adjustment

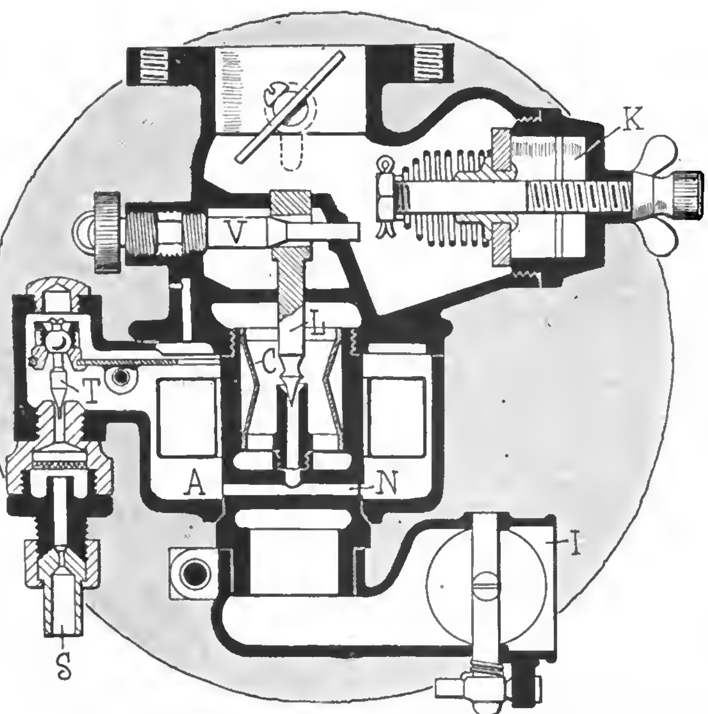

Fig. 13—Breeze carbureter uses variable jet in modified venturi passage

of the low-speed requirements of the motor. As soon as the motor speeds up and additional air is required, the auxiliary air valve opens. The second jet in the larger carbureter is placed between the auxiliary air valve and the intake passage. When the auxiliary air valve opens a stream of air passes across this secondary jet, creating sufficient suction to draw gasoline from it. An easy starting device which closes the main air supply except for a small opening and which holds the auxiliary valve tightly on its seat is furnished in the later carbureters. The priming device works on a ring and depresses the whole float instead of one particular part of it. The float arrangement is conventional, but the needle valve for fuel admission is bronze with a chrome-nickel steel seat welded in place. Outside finish is acid dipped and treated with a sand blast.

Breeze—Unique Jet Control

In the Breeze model, Fig. 13, the relative positions of the air passages are seen, there being two separate inlets I and K, instead of bringing both passages to a common opening. In the Breeze there is a venturi mixing chamber C, the spray nozzle and its adjustment being concentric with it. Fuel enters at S by the needle valve T, under control of the concentric float and flows into the chamber A. The tube N connects with the nozzle. A rather unusual needle valve adjusting feature appears on this device. The needle L is regulated by the horizontal stem V, which is tapered where it is in contact with the slot in the needle. This taper acts to vary the height of the needle as the stem is screwed in or out. It works against a spring fitted around the needle and seating on a collar just below the taper stem slot. This type is known as model SL. Model H, which is similar in principle, has been improved so as to embody an easy-starting feature. When the carbureter is primed in the regular way, a jet of gasoline is injected and confined in a pocket on the top of the air valve. When the engine is cranked, this fuel is drawn in.

S. U.—Variable Venturi Opening

In the S. U. carbureter, an English importation which, however, is now being manufactured in America, the main variation from other designs is found in the fact that the jet is set at an angle of 45 degrees in the choke portion of the jet chamber, in which chamber the passage of air is blocked by the interposition of a concentric piston P. The piston is slidable either upwards or downwards in its cylinder, being guided by a piston rod, the said piston rod carrying at its upper end the mushroom suction disk of a pair of bellows B in the suction chamber. The lower end of this piston rod carries a tapered valve, which enters the center of the gasoline jet. Between the upper portion of the jet chamber and the butterfly throttle, a duct is formed connecting to the interior of the bellows suction chamber. While the engine is running slowly, the piston obstructs the air passage across the jet, the clearance being about .031 inch. This very small area allows the air to pass with sufficient velocity thoroughly to atomize the fuel delivered. Obviously, as the throttle is opened, the suction increases, not only on the jet but also on the bellows above the disk in the suction chamber, as the said chamber is connected as aforementioned through a passageway. This has the effect of contracting the bellows, and drawing the piston further away from the jet, so affording a larger area for the passage of the air, while at the same time the tapered needle-valve is drawn further up the jet, the orifice is enlarged, and a proportionately larger portion of fuel is delivered. The taper of the needle is made such as to give a correct mixture for any position of the concentric piston. The needle is secured in the piston by a grub-screw, and can be altered in position relative to the piston. By this simple means a primary alteration of the jet orifice can be made which obtains proportionately through-

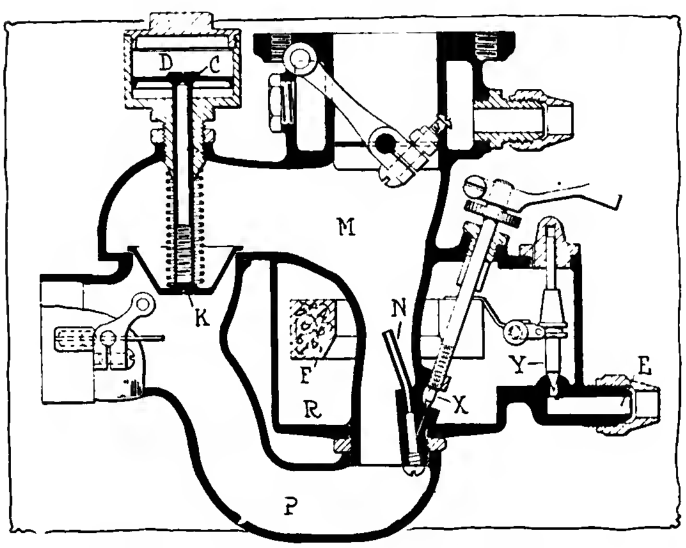

Fig. 14—Mayer model K employs fixed jet and concentric modified venturi

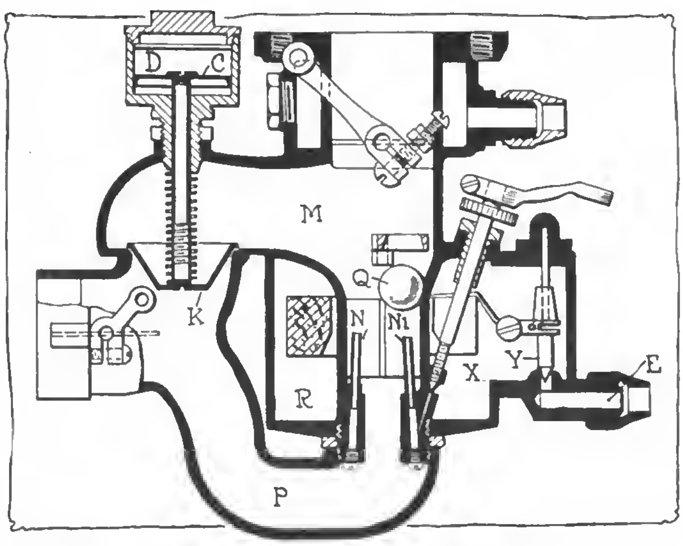

Fig. 15—Mayer carbureter uses a ball regulated auxiliary jet in new model

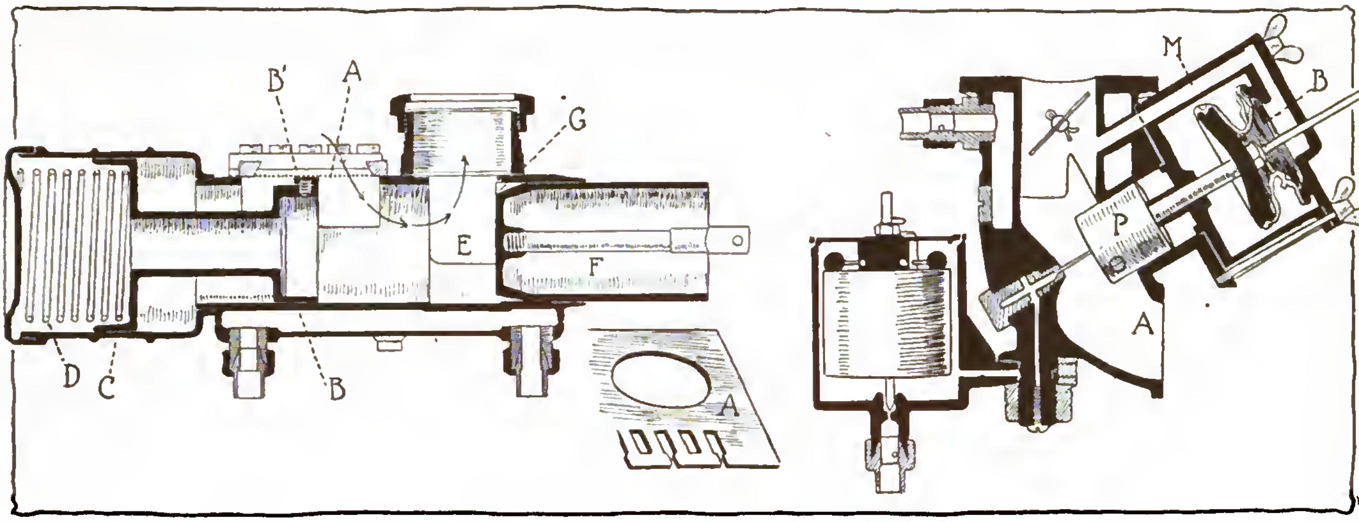

Fig. 16—Polyrhoe carbureter uses variable number of jets contained in flat plates. S. U. carbureter piston suction valve governed by leather bellows

out the scale of throttle opening, and is, in fact, an adjustable jet effect. At the same time the longitudinal section of the needle can be altered by emery paper or filing to suit the particular requirements of any engine in any particular position of throttle opening.

This instrument has behaved so satisfactorily in Europe that it has not been necessary to make any changes in it for the coming year. One of its chief merits advanced is its ability to operate for long periods with the engine turning over slowly and at the same time having the ability to accelerate rapidly without choking. When the instrument is fully open, it gives an unusually free air passage to the engine, and in tests has run a standard six-cylinder car at a speed of 3,700 revolutions per minute on the bench, and yet giving the ability to throttle for ordinary running without difficulty. A special type of this instrument is manufactured for sleeve-valve motors.

Air-Friction—Variable Air Passage

The Air Friction carbureter, Fig. 17, is so called for the reason that the air passing through the conical valve V surrounding the nozzle R raises or lowers this valve in proportion to the throttle opening, thus automatically controlling the mixture. The rising and falling of this valve gives a variable venturi action, thereby controlling the air pull on the gasoline issuing from the jet. The spray nozzle R serves to spread the fuel, and presenting a large wetted surface to the incoming air entering through S. The nozzle opening is regulated by the thumbnut N, and is held in position by nut Y. There is a single air inlet screened at A and which may be closed by a butterfly B. The float mechanism is conventional, consisting of float X linked to needle valve F. The entering fuel is strained at G. The outlet tube is very short, being controlled by throttle L.

Mayer—Adds Double-Jet Model

With the object of preventing the tendency to flutter and to fly wide open with more or less of a jerk on account of suddenly increased suction, the Mayer carbureter has its auxiliary air valve provided with a dashpot which controls the operation of the valve. This feature is indicated by D, while the piston which works in the small cylinder C. In addition to working against the air in this cylinder, the valve K acts against a spring as well. Such a construction necessarily requires accurate adjustment of the spring with relation to the dashpot position, but once properly mated relative to each other, the feature should prove of advantage.

Fig. 15, which shows the latest Mayer type, a two-jet device, illustrates the placing of both of these nozzles N and N_1 directly in the main air passage P. The slow-speed nozzle N communicates directly with the mixing chamber, whereas the auxiliary jet N_1 comes into play only at higher speeds, or when the vacuum created is great enough to overbalance the weight of the ball Q, lifting it from its seat and allowing the entrance of additional fuel to supply the greater demand.

The constructional features of the Mayer carbureters, which appear in three models, G, H and K, are all along the same lines, except that type G is not provided with dashpot air control, and both G and H are single-jet instruments. In these two models the jet is located in the position which the auxiliary jet N_1 occupies in model K, Fig. 14. The needle valve adjustment is at X, while the gasoline enters the float chamber R at E, its flow being controlled in the usual way by the needle valve Y linked to the float F. The primary air passage P extends under the float chamber and passes the nozzles, while the auxiliary air combines with the mixture at M. Water-jacketing of the passage to the manifold is done.

Polyrhoe—A Multi-Jet Example

The constructional peculiarity of the Polyrhoe carbureter, a foreign one, lies principally in connection with the jets. These take the form of a series of slots cut in brass plates of known gauge. Fig. 16 shows on an enlarged scale a portion of one of these plates A of which there are two to a carbureter. The actual jet orifice is rectangular or nearly so in section. B is

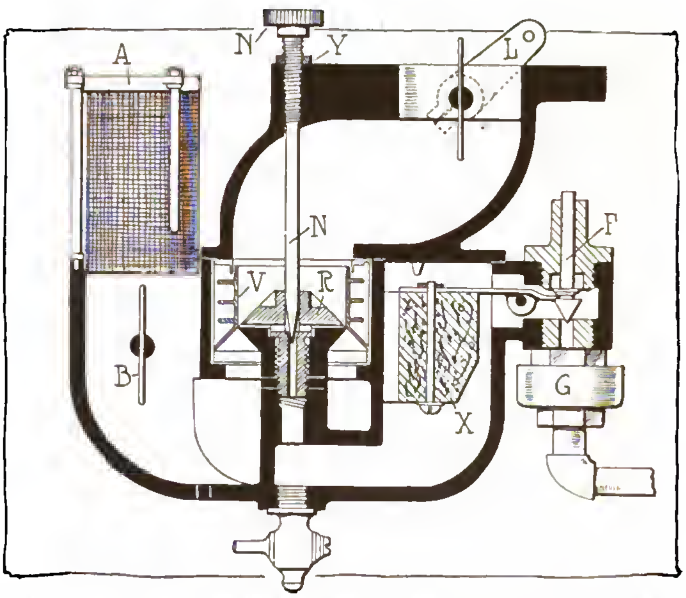

Fig. 17—Air Friction variable jet carbureter with single adjustment

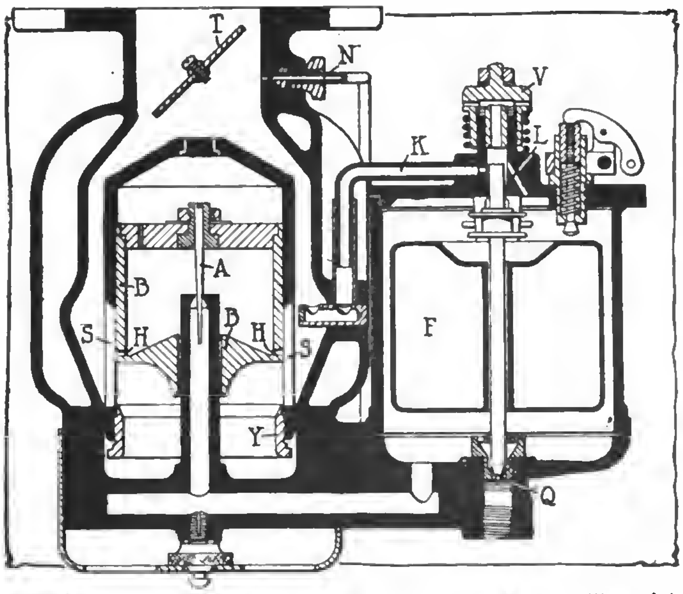

Fig. 18—Newcomb carbureter has eccentric float and auxiliary jet feature

a piston sliding freely in the body of the carbureter and having on its upper part a lip B^1 secured to it. This lip controls the quantity of air passing, the passage of which air is suggested by the arrow shown. Air flowing into the carbureter therefore must of necessity pass in close proximity to the series of jets A and its inductive influence is felt on all the jets that are situated on the right hand of the lip. To the piston B is attached by a neck a second piston C of larger diameter and this piston has at the back of it a helical spring D. The purpose of this spring is to tend to close the air supply when there is only a small negative pressure in the mixture chamber E. It will be understood that the pressure or rather negative pressure in E is at once communicated to the spring side of the large piston C. Thus when the suction of the engine is a strong one a considerable negative pressure is caused at the back of the piston C and the pressure of the atmosphere acting upon the other side of the piston compresses the helical spring and moves the small piston B to the left, thus by means of the lip B^1 permitting more air to flow and at the same time opening up a greater number of jets.

F is a piston throttle of usual construction, having a slot G close to the engine branch for permitting slow running with an all but closed throttle. It should be stated that the row of jets is situated slightly above the level of gasoline in the float chamber and the difference of pressure under which the instrument works is just sufficient to cause the fuel to flow from the jets which happen to be in operation at the time and to cause an effective spray.

The proportion of air and gasoline opening are constant at all throttle positions, but in order that these may be varied at times to suit existing weather conditions, an air slide is provided over the rectangular air opening and having in view the fact that this slide works at right angles to the movement of the control piston and lip its effect upon the air supply will be readily understood.

The Polyrhoe carbureter belongs in the true sense of the word to the multi-jet type, for there is one jet to each .063 inch of air port—or as the makers call it throat—opening. The size of the jet is about .006 inch deep by .025 inch wide. That the carbureter is good for slow running is proved by the fact that a four-cylinder engine has been run down to 140 revolutions per minute and a six-cylinder to 100 revolutions per minute.

There exists in the case of this carbureter a very small percentage of carbon monoxide in the exhaust gases for the percentage does not exceed 0.2 when the engine is loaded and 0.8 when the engine is running light. The proportion of CO_2 varies from 13.4 per cent. to 13.8 per cent. when the engine is loaded, and from 13.2 per cent. to 13.5 per cent. when the engine is running light, the consumption of spirit of 0.760 specific gravity being at the rate of 4 to 10 miles per gallon on the track at a speed of 20 miles per hour.

The salient features of this carbureter are: A large number of rectangular jets formed by the superimposing of two perforated and slotted plates, the jets being controlled by a slide which also governs the air supply, such slide being operated by the air suction. A hand-operated shutter which varies the proportion of air in the mixture throughout the entire range of the carbureter.

Feps—No Ball or Spring Valves

The Feps carbureter is of the fixed-venturi type with an auxiliary gasoline jet and an auxiliary air valve for controlling the suction at the jet when the engine speeds rise to such an extent that an incorrect mixture is given by the main fixed jet in the venturi. The carbureter is free from springs and ball checks. Fuel is admitted by a conventional concentric float, the only unusual feature being the insertion of a conical screen C, Fig. 19, in the gasoline line through which all the fuel must pass.

The passage to the inlet manifold rises vertically from the venturi and the course of the fuel is through the low-speed jet J, after which it is mixed with the air which enters the venturi passage at the bottom. After the speed of the engine has increased to such an extent that the suction on the jet is great enough to give too rich a mixture, or, in other words, at intermediate engine speeds, additional air is admitted through the auxiliary air valve H. This leather-faced valve is held on its seat solely by its own weight. Greater suction lifts the valve higher as the suction increases, thereby increasing the air passage formed between the edge of the valve and its seat. An adjustable stop limits its final lift. This stop is controlled by the knurled screw F. When the suction increases beyond that necessary to lift the auxiliary air valve against the stop, the auxiliary jet comes into play: Increased suction causes the pull on the auxiliary air valve to increase, and this causes it to pull against the stop which limits its lift. The stop is movable and is attached to the metering pin which controls the opening of the auxiliary jet, hence when the pull increases the metering pin is lifted and the auxiliary jet comes into play. The supply of air is still further increased by the augmented lift of the

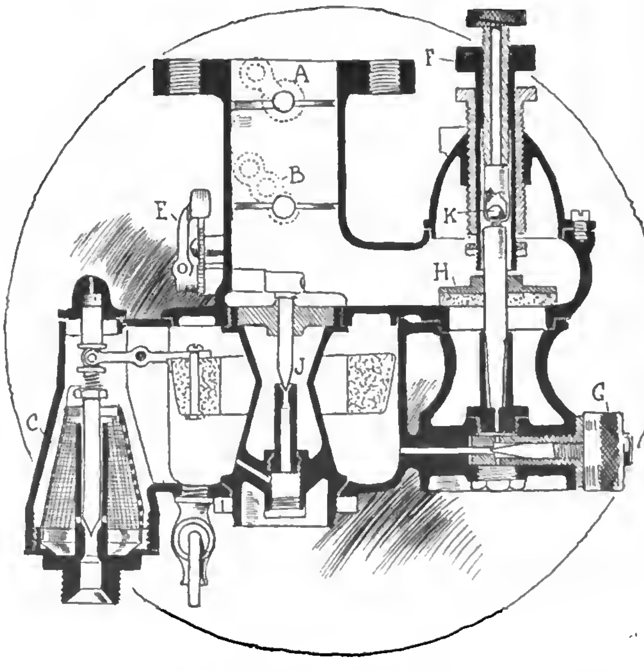

Fig. 19—Feps new carbureter without any spring or ball valves

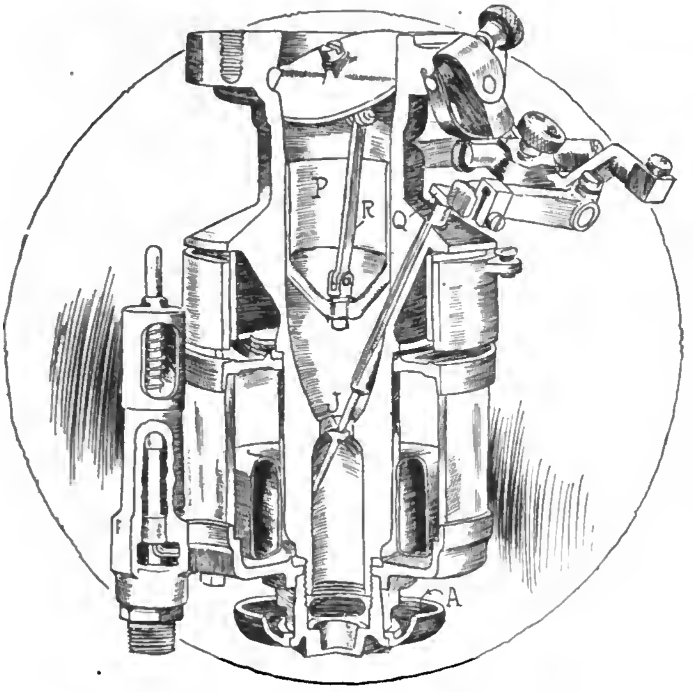

Fig. 20—New Miller has mechanical control for fuel and air supply

auxiliary air valve along the metering pin, and so the required lean mixture for high-speed running is obtained.

The carbureter has an easy-starting tube which extends from the float chamber to a point just below that at which the carbureter is connected to the manifold. All air supply may be cut off by a shutter A, confining the suction to the easy-starting by-pass and furnishing a supply of gasoline to the motor.

The carbureter has an adjustment for intermediate speed and another for high speed. The first is by means of the knurled screw F, which determines the lift of the auxiliary air valve, and the second is by the knurled screw G, which determines the gasoline flow to the auxiliary jet. Besides these two the primary jet can be regulated by means of the needle valve, the adjustment being made by turning the link E. The throttle is placed a little lower than usual at B.

Carter—Spirally Perforated Jet

In speaking of multiple jet carbureters, we ordinarily refer to the types which utilize two or more nozzles, one being the primary or main office and the others being merely auxiliary jets which come into play with increased motor suctions.

Although making use of this principle of supplying increasing amounts of fuel, automatically, by bringing additional jets into play in proportion to greater engine speeds, the Carter instrument, Fig. 21, accomplishes this result in a mechanically different way. Referring to the sectional view; the multiple-jet fuel tube B, located in the funnel K, has a multiplicity of small holes or jets arranged spirally around its cylindrical surface. As a vacuum is created in the carbureter by the suction of the motor, the fuel rises and falls in the tube B accordingly as the motor speed changes. The fuel in the tube sprays out through the small jets, the number operating depending upon the height of the fuel. By the use of a multiplicity of very small openings, the gasoline is finely divided up into a mist, which aids in its union with the air. By this spiral arrangement of the jets, each small emission of fuel receives its own proportion of the air supply. The main jet which is alone in operation at low speeds is located at the bottom of the tube B. The main air opening is above this lower orifice. It is located at D. The mixing chamber proper is at H. The carbureter has a spring controlled auxiliary air valve A, with the operation of which valves we are already acquainted.

A rather unusual feature of the Carter instrument is the ball float E which rests upon the lever F. The latter is pivoted and operates the needle supply valve G in the usual way. Another noticeable point is the tube C, which is a preventive of strangling at low speeds. It keeps the mixing chamber H dry and free from fuel which would tend to condense the vapor generated. This tube extends into the manifold above the throttle and receives the full motor suction. The tube B is provided with an adjustment so that the fuel supplied at low speeds may be regulated. This device should furnish a well saturated mixture at normal operating speeds due to the opportunity afforded for the spreading out and fine division of the fuel.

Miller—Manually Controlled Valves

The new Miller carbureter is positively actuated, Fig. 20, being without springs. Pressing the accelerator pedal or opening the throttle controls the suction at the jet just as mechanically as it does the opening of the butterfly valve admitting the gases to the intake manifold. The carbureter, a concentric-float design with a single jet in the venturi, has a fixed air opening at the bottom of the venturi, and the air passing through this in connection with the jet in the venturi takes care of low engine speeds. When the throttle is opened further, speeding up the motor and causing a greater suction to occur at the jet, an extra supply of air is furnished in the following manner: Connecting the throttle butterfly valve and an air piston P in the cylindrical passage above the venturi is a short connecting rod R. When the throttle is opened, the piston is pulled up by this rod and uncovers air ports in the wall of the passage. The further the throttle is opened the more air ports are uncovered by the piston and the more air admitted.

In order to supply the increase in fuel necessary at higher speeds the needle valve is opened by the throttle mechanism through a cam arrangement on the head of the needle valve Q, thereby opening same through a spring in the needle valve housing.

Easy starting is obtained by a primer which depresses the float and floods the float chamber. The points at which the needle valve is opened and at which the piston begins to admit air through the annular auxiliary opening are adjustable. A removable hot-air attachment is also a feature.

Newcomb—A Constant Suction Type

A type of carbureter which works on the constant-vacuum principle and which utilizes a metering pin arrangement for automatically controlling the amount of fuel in the mixture is the Newcomb, Fig. 18. The metering mechanism is shown at B, while the pin proper which regulates the flow of fuel from the

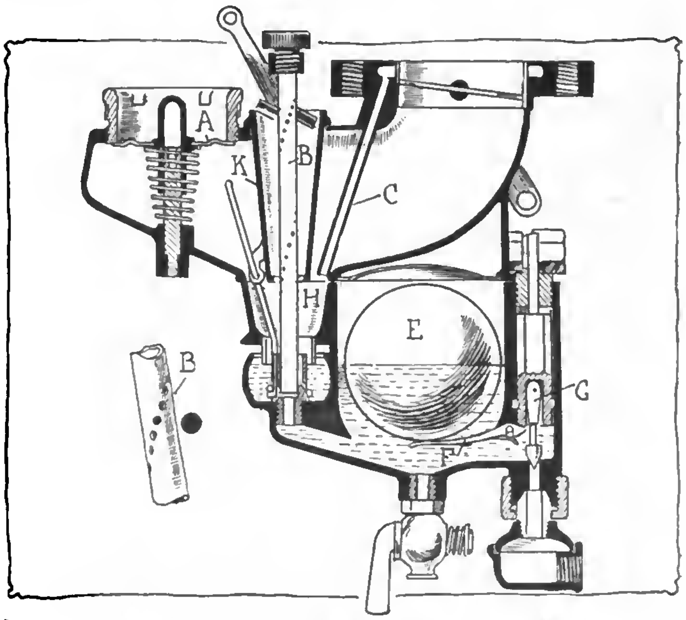

Fig. 21—Carter has ball float and numerous jets varying with suction

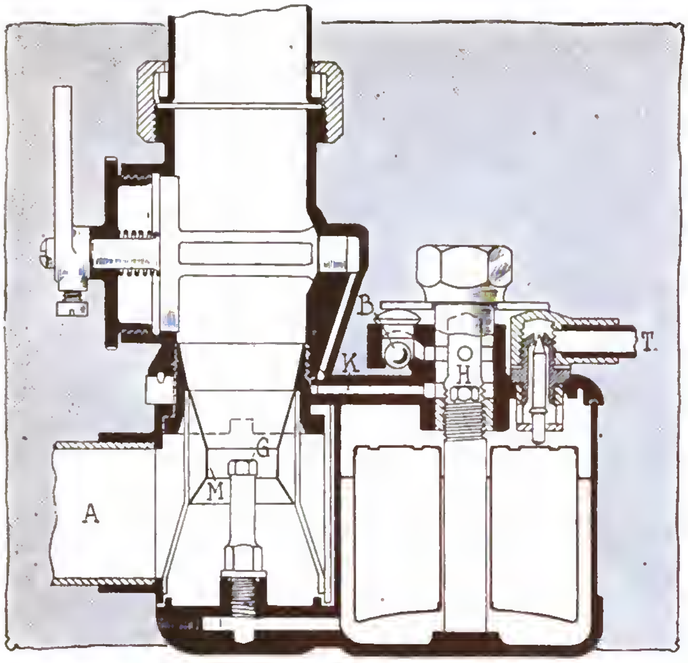

Fig. 22—Solex carbureter is a French eccentric float design

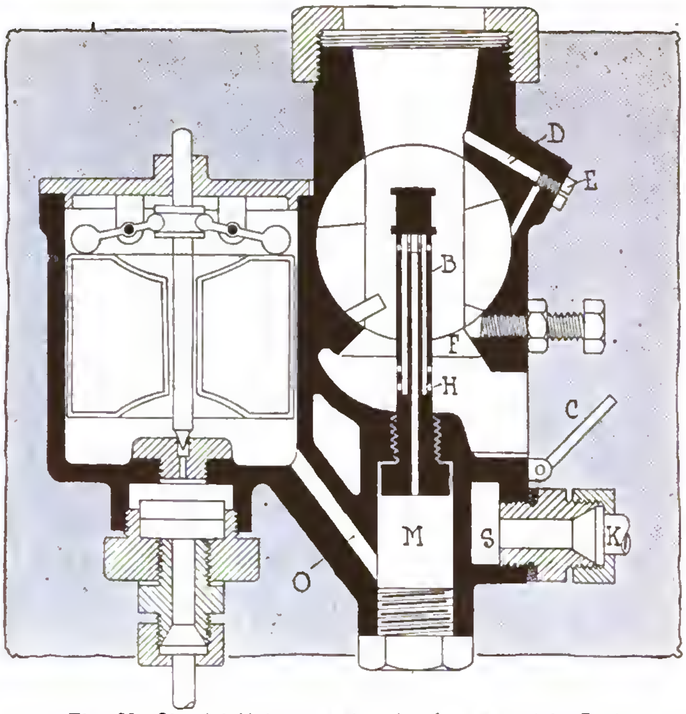

Fig. 23—Claudel-Hobson carbureter has eccentric float

nozzle C is indicated by A. This metering arrangement is really a small piston working up and down in the cylindrical body of the carbureter. When at its lowest position, B rests upon the upper edge of Y. In operation the metering mechanism floats in some such position as that shown.

Air enters through the bottom of the carbureter and flows through the slots S, the amount of opening of which is governed by the position of the plunger B. Holes H in the bottom of the plunger register with these slots S and allow the fuel issuing from the jet to flow through and combine with the air. The height of plnnger B is controlled by the throttle opening which increases or lessens the motor suction, and changing the pressure difference on the upper and lower faces of the plunger, that on the lower face is of course constantly atmospheric, being open and free.

Regulation for quality of mixture is done through the vacuum valve V above the float chamber. The valve V is so constructed that the flow of air from the outside may be increased or decreased by turning the valve up or down. The small passages are here shown wide open, allowing air to pass from the outside through the tube K to the mixing chamber. A tube L also connects this passage with the float chamber. When the valve V is adjusted for lean mixtures, it is screwed down so that there is little or no air passage to the outside. Thus when the motor suction becomes high enough, it draws through tubes K and L, communicating with the pressure above the gasoline in the float chamber and serving to prevent as great a flow to the nozzle, and making the mixture weak. When V is set for rich mixtures, the air passes directly from the outside to the mixing chamber and does not act against the flow to the nozzle, allowing proportionately more fuel for the same amount of air and giving a proportionately richer mixture.

This carbureter is fitted with a priming device for easy starting. It consists of an auxiliary fuel nozzle N connecting with a tube conveying gasoline from the float chamber. When the motor is running, very little fuel flows through this orifice, but when starting the throttle is turned backward through a slight angle, bringing it above the valve, and subjecting it to the strong suction which draws in pure fuel.

The float mechanism is standard and embodies the metal float F for raising and lowering the needle Q. For regulating the opening of the nozzle C provided by the pin A, the regulating collar V is provided, which raises or lowers the seating position of the plunger B. The needle is so positioned when normal that the fuel nozzle is nearly closed when plunger is on its seat, giving the fuel a slight lead over the air for slow running.

Claudel—Jet Inclosed in Tube

One of the foreign carbureters which has perhaps as big a European following as any is the Claudel-Hobson, Fig. 23, which has as its peculiarity the fact that its single jet H is inclosed in a small diameter vertical tube B perforated at the top and bottom. The throttle valve, which takes the form of a cylindrical shell or drum, is situated close to the jet, so that the valve practically takes the place of the usual choke tube.

The jet is covered by a tube B, as just stated, drilled at the bottom with holes H and also at the top at the same level as the jet. When the throttle is shut, the top part of the jet is in the mixing chamber and the gasoline is sucked through the top holes of the tube, while the suction is relieved by a proportionate quantity of air entering through the holes of the bottom of the jacketing tube, which is in direct communication with the atmosphere outside the regulator C, thus insuring a perfect spray and an accurate proportion of gasoline passing into the mixing chamber while the throttle and air strangler combined are so cut that, when opened to whatever extent, for the engine to pick up, accurate proportions of air and gasoline are claimed to pass into the cylinders.

Briefly, the action of the carbureter is as follows: When the throttle-drum is full open, there is a perfectly clear way through, so that the minimum possible obstruction is offered to the ingoing mixture, thus assuring as full a charge as possible. To further this end to an even greater extent still for maximum load that portion of the passage beneath the union-nut is tapered so as to gradually increase the diameter right through the throttle-drum and up to the induction-pipe fitting, while close beneath the throttle-drum is a sharper taper in the opposite direction, opening downwards, with the object of obtaining, injector fashion, all the flow that it is possible to get into the large bore of the induction pipe.

Projecting up into the throttle-drum, and therefore centrally placed within the main air passage when the throttle is fully opened, is the above-described special jet, in which the gasoline is maintained at an approximately constant normal level by a float of the usual character. Immediately beneath this jet there is a jacket through which some of the circulating water from the engine is allowed to flow, and which warms the gasoline before it actually enters the jet and assists in its atomization.

The shape of the throttle-drum already described is peculiar. The passage through it is such that the area round the lower portion of the jet is reduced at the same time that the outlet to the induction pipe is being diminished in size.

There is a small by-pass D which makes communication when the throttle is at a particular position, between the lower part of the carbureter and the upper part. The effective size of this by-pass orifice may be adjusted by means of the screw E, the end of which may be screwed so far in as to project across and thus restrict the lower part of the by-pass passage. A further adjustment is also provided by the screw which affects the richness of the mixture. When screwed out, the area of the choke tube is increased and the velocity of the air up round the jet is decreased. Though this adjustment makes but little difference when the throttle-drum is open, yet when nearly closed it becomes of considerable importance in regulating the air and fuel supply for slow running.

With this carbureter subsidiary warming is generally used.

Solex—Throttle Works Second Jet

The Solex, an imported carbureter of the twin-jet type, has the second jet in a most unusual position in that it is neither above nor below the throttle valve, located in the vertical pipe leading to the motor, Fig. 22, but, as a matter of fact, is precisely on the same level with this valve and enters the right end bearing of the throttle, which is explained as follows: The first or main jet G is of conventional construction and is surrounded by a bi-conical venturi M. Now for the secondary jet and its method of operation. To understand it, keep in mind that the throttle is capable of being moved axially by the simple expedient of screwing up or unscrewing the retaining cap, shown at the left end of the throttle. Between this retaining cap and the disk on the throttle shaft is a coil spring which aids in this adjustment. The throttle is composed of two thin walls inclosing a chamber and the pivot of the throttle on the right-hand side in the figure has a small hole in it; this hole communicates by means of the passages with a small chamber containing a ball valve B opening inwards towards this chamber. This same chamber has within it a supplementary jet deriving its supply of fuel from the main float chamber. These, briefly, are the constructional details, all of which are clearly shown in the illustration.

During slow running the throttle assumes a comparatively horizontal position. The induction current therefore passes through the crescent-shaped opening formed by the curved end of the throttle and the body of the carbureter. There is, then, in the float chamber formed in the throttle itself a depression intermediate between the extreme rarefaction in the region above the upper wall and the comparative absence of vacuum round the main jet below the lower wall. This depression is just sufficient to draw from the auxiliary jet the small amount of gasoline necessary to maintain a low rate of engine speed. The shut position of the throttle corresponds to a considerable angle so that no very nice adjustment is necessary for slow running; this adjustment is made in the first instance by operation of the screwed cap as just described. When the engine increases speed the depression increases and the small ball valve B lifts.

Hoyt—Metering Pin Regulation

The Hoyt carbureter, Fig. 26, operates on the constant-vacuum principle. It is provided with two jets, the low-speed jet A being adjustable for a fixed position while the auxiliary jet B is controlled by a metering pin mechanism C. The auxiliary needle has a long slim taper, but instead of being conical in form it is flat on three sides, the object of this being to produce three thin sprays, thus aiding in the splitting up of the fuel. This needle is raised or lowered by the plunger C, the amount which it is raised depending upon the suction; also the higher this plunger, the greater the amount of air passing through the auxiliary air valve E, which principle is similar to that of other metering pin types. The priming air passage supplies air to nozzle A when running at low speeds when the metering mechanism is seated is shown at D. Needle G controls a passage leading to the port F at the bottom of the air valve which when opened lowers the pressure under the valve, retarding its upward movement and thus putting greater pressure on the gasoline, making a richer mixture, the richness of which depends upon the amount G, is opened. In this carbureter the flow of gasoline is controlled by the air valve, a vacuum replacing springs.

Excelsior—Ball-Suction Control

A peculiar carbureter design which compensates for higher speeds by automatically admitting more air as the suction increases is the Excelsior instrument, Fig. 28. The distinguishing feature is the use of a ball B in the mixture tube. When the engine is running at low speed, the suction is small, hence there

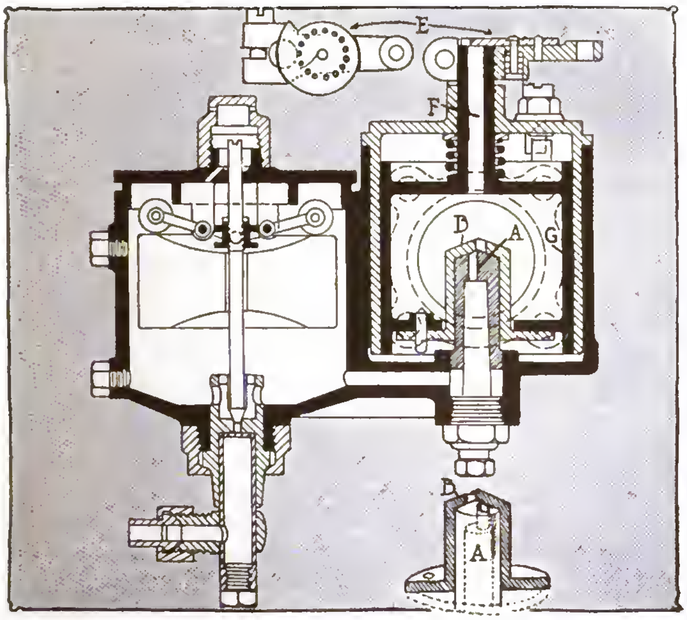

Fig. 24—White-Poppe is an eccentric carbureter with a variable adjustable jet

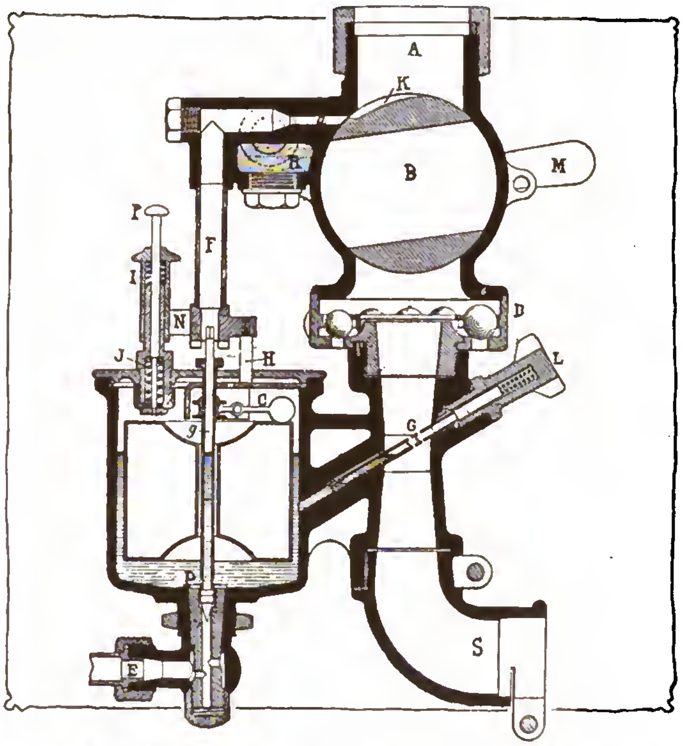

Fig. 25—G & A carbureter now has secondary jet above float chamber

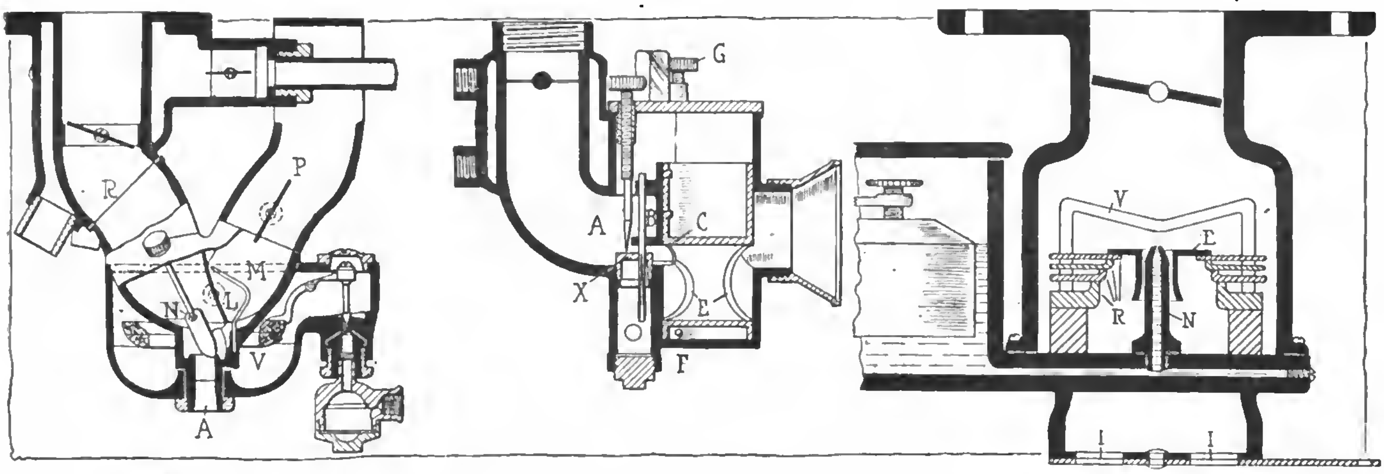

Fig. 26—Left, Marvel H with diagonal needle controlled jet; center, Hoyt metering pin control; right, Krause variable venturi eccentric carbureter

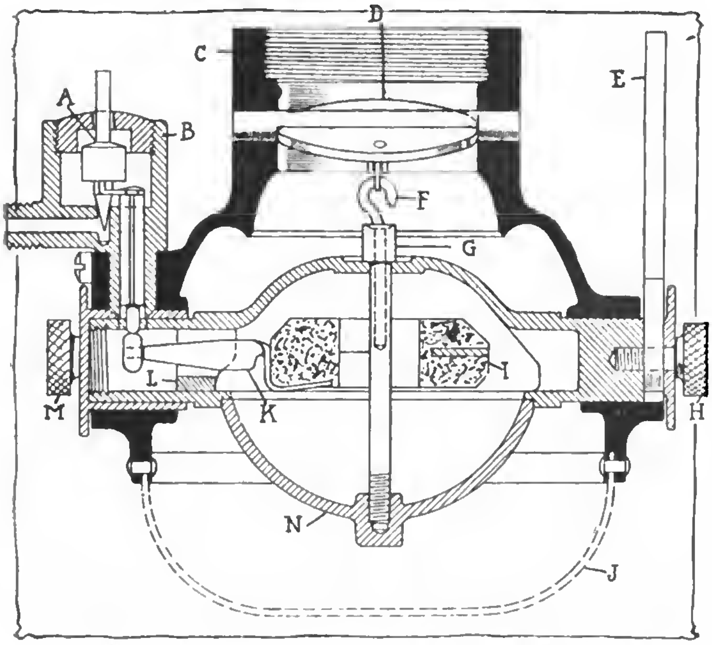

Fig. 27—A B C carbureter contains six jets in rotating float-chamber

is little tendency for this ball to be drawn upward toward the manifold connection. The tube becomes larger in section as it nears the manifold and is of the least diameter where the ball is shown. With increased vacuum, it floats in a higher position, as indicated by the dotted lines at C. In some such position as this, there is a wide passage for the air around the ball. Thus, the greater is the suction, the greater becomes the air clearance.

G & A—Adds a Two-Jet Model

The new Grouvelle and Arquembourg, or as it is generally called, G & A carbureter, Fig. 25, is of the eccentric-float, double-jet type. An unusual feature is that the auxiliary jet is concentric with the float while the main jet is set in a long venturi passage concentric with and below the intake manifold connection.

The normal air intake is located at S below the venturi and the jet is located at G at the narrowest part of this passage. As may be noted, the jet enters the venturi passage at 45 degrees. Additional air is obtained at greater engine speeds through the passages at D, closed by twelve metal balls of different sizes. This gives the required leaner mixture for intermediate speeds. At low speeds the auxiliary jet acts alone. The groove K in the throttle B allows the gasoline to be drawn up through the passage F. At the bottom of this passage the small auxiliary jet is located. It is indicated by G. Around this jet is an annular open passage through which air is drawn. The priming device is shown at P, I and J. When the throttle is open wide enough for the main jet to come into operation the air is first taken through and then by lifting one ball after the other as the motor increases its speed. The course of the gasoline is through E, and though the usual form of float chamber P. The carbureter is hot-water jacketed at R.

A B C—Tilting Float Chamber

In the A B C carbureter a pivoted float chamber which rotates about a horizontal axis in conjunction with the throttle-valve action is the feature of the A B C carbureter. The latter is of concentric design. The float chamber is a flattened sphere suspended in the air passage; above the float chamber and situated in the intake passage in the butterfly throttle. The float chamber and throttle are linked together in such a manner that when the float chamber is tilted about its axis the throttle is opened. Piercing the wall of the float chamber above its equatorial line on one side is a series of five jets of different capacities and arranged at different heights; on the other side of the float chamber a single jet for low-speed and compensating work is located. When the float chamber is tilted, gasoline fills the jets one after another as the tilt increases; incidentally the throttle opening grows wider and wider. The more jets are opened the greater becomes the cross area of the air entrance around the float chamber.

C R G—Uses Three Venturis

The C R G carbureter is unique in that it contains three separate and independent venturi tubes in one casing, their relative location being such that if connected by lines, an equilateral triangle would be formed in the carbureter. Three jets or nozzles are used, each being located centrally in one of these venturi tubes. The concentric float chamber surrounds the three venturis. When running slowly, the smallest of the three venturis is in action and operates at speeds of from 4 to 12 miles an hour on level roads. Above the latter speed and up to 35 miles an hour the second venturi comes into action and works in conjunction with the first up to a car speed of 35 miles an hour. Above this speed all three jets operate. The air inlets for each of these venturis is separate and in order to get the gasoline started through the nozzle before the air comes into play a priming disk is fitted over each air passage.

White & Poppe—Eccentric Jet Control

The White & Poppe carbureter is of the single, variable-jet type and has a rotary throttle B working in conjunction with the jet-regulating device. The latest addition to the carbureter is a corrugated copper device for silencing the noise of the ingoing air. Fig. 24 shows a section in which A is the single jet having a hole drilled out of center into its main passageway. Fitting gasoline-tight over the upright jet is a regulator cap B which has a hole of corresponding size and eccentrically drilled in its upper end. A rotary movement of the cap obviously has the effect of altering the effective opening of the jet. The regulation cap has a flange at its base by which it is attached to a cylindrical throttle valve S, which latter is operated when desired by the lever. The correct proportions of air to gasoline openings is in the neighborhood of 500 to 1, and the respective openings of the air throttle and regulation cap are arranged in such manner that their proportions are maintained at all positions of the throttle lever.

In the later type of carbureter an ingenious arrangement is furnished for varying the amount of constant air supply to the instrument. A hole F situated immediately over the jet is partially closed by a cam-shaped plate E. This plate can be lifted out of engagement with a small peg on the throttle lever and partially rotated so that the edge of the plate covers more or less of the constant air port F. In this manner an extremely fine adjustment is obtained. A small stop is provided close to the air inlet, known as the slow-running stop, for making it possible to instantly bring the throttle lever to the best position for slow running.

Krause—Maco—Marvel—Shain

Although conventional in most respects the Krause carbureter, Fig. 26, utilizes a method of controlling the air supply in proportion to the suction. The air enters through the bottom of the device through the adjustable air inlets I, and passes upward by the nozzle N. As the motor suction increases, the air controlling ring valves R are successively raised from their seats and slide on the guides V. Thus the air passing through is in proportion as the opening is made larger by the raising of these rings. When the engine is cranked, air enters only through the automatic priming valve E close around the nozzle, serving to draw enough gasoline for starting. The operation of this carbureter is a constant-suction type with what is in reality a variable air gap.

Extreme simplicity marks the Maco carbureter. It is of the concentric-float, fixed-venturi type. The air passes in through the bottom of the carbureter, up through the venturi and around the spray nozzle. A spring-regulated auxiliary air valve takes care of the mixture at increased suction due to higher engine speeds. There are two adjustments: The needle valve in the venturi jet may be regulated by turning the knurled screw above the carbureter and the tension on the auxiliary air valve may be regulated causing this valve to open earlier or later according as to whether the pressure is made higher or lower.

The use of more than one jet in an instrument assumes several forms; an unique adaptation being that shown in Fig. 26, which is a sectional view of the Marvel. This device is provided with a primary nozzle N which extends into the mixing chamber diagonally and which is controlled conventionally by a needle valve; and with an auxiliary or high-speed nozzle M which extends to the upper part of the mixing chamber and back of a butterfly valve L. This latter is held in a closed position by an adjustable tension spring. When the engine is running at high speed, the suction overcomes the tension in the spring and the valve L is opened admitting air through P in proportion to the opening and drawing auxiliary fuel through nozzle M which connects with the fuel chamber through the tube V. When the nozzle N only is in use, air enters through the fixed tube A only. The passage to the motor is at R. Float feed arrangements are in accord with American practice.

The Shain carbureter, Fig. 29, is distinguished by the fact that it has no float regulation but a ball B rests upon the gasoline supply pipe opening and is lifted from its seat by the pressure of the gasoline below and the suction of the motor above. Air is supplied through the ten open air ports surrounding the ball. The greater the suction of the motor the higher the ball will be lifted and the greater the amount of air drawn through the air ports. The ball revolves, owing to the suction above and the pressure below, giving a spraying action to gasoline.

Sudden Expiration of French Patents a Constant Danger to Some Non-French Holders—Odometer and Revolution-Counter of Interesting Design—Keeping Cars Young—Cheap Protection for Grade Crossings—Improvement of Road Tar

LAPSING of French Patents.—A recent decision in a patent case of the Thomson-Houston company against the street car company of Lille, France, rendered on appeal to the Court of Cassation by the latter calls attention to the risk of having their French patents declared invalid which confronts some non-French patentees and assignees.

The French patent law of 1844 says in article 29: "The author of an invention or discovery already patented abroad can obtain a patent in France, but the duration of this patent shall not exceed that of the patents previously taken abroad."

This paragraph is subject to varying interpretations. It is admitted that by virtue of this article the French patent granted for the same term as the foreign (non-French) patents is affected not only by the normal expiration but also by any accidental lapse of these patents, even if the cause of the voidance is not recognized in French laws. The Court of Paris found differently in a decree of May 16, 1863, in a case where a patent had become void in Belgium through failure to pay the required annual tax, but this decree was reversed by the Court of Cassation, January 14, 1864. It is held to be the purpose of the article to protect French industry and therefore not to permit a monopoly in France on something which can be manufactured freely abroad.

But what is to be understood by "abroad"? To cause the French patent to continue in force, is it sufficient that the invention is protected in any one foreign country? Or, on the other hand, is it sufficient, in order to cause its lapse in France, that its manufacture has become free in a single foreign country?

The natural sense of the article may be invoked in favor of the first opinion. Otherwise an inventor might find himself punished for his excess of precaution in taking out patents in all the countries of the world. Suppose, for example, that he takes out patents in the principal countries and also in Bulgaria. But after a year or two he abandons the idea of exploiting the Bulgarian patent and lets it go by default of payment. Should he then be deprived of his French rights, though he would have remained protected if he never had taken out a Bulgarian patent?

This consideration inspired the Court of Douay when on November 19, 1907, it rendered a decision in favor of the Thomson-Houston company.

The Thomson-Houston company had bought from Knight and Potter, the inventors, the French patent relating to a method for adjusting electric machinery. The method had already been patented in Sweden and in Belgium, but in 1907 the Swedish patent lapsed in default of the annual payment, and the street car company of Lille assumed that for this reason the patent had fallen into the public domain. In this the Court of Douay did not uphold it. Now, however, the Court of Cassation by its decree of November 5, last, has reversed the decision of the Court of Douay, maintaining that it follows absolutely from the purpose of the law that the French patent must lapse when any previously obtained foreign patent lapses for any cause.

This decree may be criticised for not interpreting the text of the law but the intent of the legislator and even for interpreting the latter incorrectly. The member who introduced the law of 1844 said in the Chamber of Deputies with regard to article 29: "We should not chain to a monopoly in France something which may be produced free of all restrictions everywhere else (*Il ne faut pas enchaîner en France par le monopole ce qui, partout ailleurs, serait libre de toute entrave*)." The words "everywhere else" conflict with the decree of the Court of Cassation.

At all events the applicability of this decree is now much restricted through the convention of December 14, 1900, in which there is found the following clause: "The patents demanded in the different contracting states by persons admitted to the benefits of this convention shall be independent of the patents obtained for the same invention in other states, whether these are or are not members of the union (*dans les états adhérant ou non a l'union*)." In accordance herewith, citizens of the countries which took part in this convention are no longer subject to seeing their French patents [or patents granted in any of the other countries interested.—Ed.] suffer from the reaction of accidents befalling one of their other foreign patents. These privileged countries are numerous, including Belgium, Brazil, Denmark, Spain, the United States, Great Britain, Italy, Japan, the Netherlands, Portugal, Servia, Sweden, Switzerland and Tunis.

In the Thomson-Houston case the Court of Cassation disregarded this convention, although Sweden and Belgium are among the parties to it, because the facts of the case existed before the convention went into effect, which was in 1902. This shows the slowness of French legal procedure, since an action for infringement filed in 1903 and referring to facts antedating 1902, does not reach the Court of Cassation until 1912. It may be noted, by the way, that the case is not yet finished, as the Court of Cassation has remanded it back to the Court of Amiens. This, it may be hoped, will prove to be only a simple formality.—From *Le Génie Civil*, December 14.

[On the basis of facts presented in the foregoing it still seems possible that the American assignee of a French patent obtained from a Russian, a Norwegian, a Greek, an Austrian or a German patentee would forfeit his rights in France if any other patents secured by the inventor lapsed.—Ed.]

—

NEW Odometer Principle Described.—The makers of the Gnome motors in France bring to the attention of the French industry an odometer which they have found very reliable in practice despite its apparently complicated mechanism in which the parts are small and delicate. The idea of the maker of this instrument seems to have been to avoid the use of a centrifugal governor in direct connection with the index hand which tells the speed variations and to measure the latter by bringing a roller which follows all the speed variations in a measurable and slowly self-adjustable relation to a disk revolving at a constant speed not too far removed from the average motor speed. The principle is explained as follows with reference to the accompanying diagrams, Figs. 1, 2 and 3:

The Behrens odometer is composed of two distinct mechanical movements whose interaction gives the number of revolutions per minute for any vehicle or motor. Where the driving shaft enters the device it transmits motion to both movements through a small train of gears, the ratio of which may be changed to suit the requirements in each case.

The first movement is shown in diagrammatic elevation in Fig. 1, and is intended to secure the rotation at constant speed of the disk D. The spindle of this disk is actuated by the driving shaft through a friction clutch T, which consists of a spiral spring whose free end expands against the interior of a drum, so as to permit small relative speed variations without slip. At the other end the shaft of D is geared to a small plate P, which turns with its spindle while capable of sliding in or out on it under the influence of a ball-governor which, at increasing speed, tends to draw the plate against the brake-screw B, which is mounted on a small leaf spring. The plate P is thus constantly in contact with the brake-screw, and the brake effect may be sufficient to make the clutch T slip. The disk D is hereby made to turn at constant speed.

The second movement, Fig. 2, comprises a metallic roller G, which is in frictional contact with disk D of the first movement and of an ingenious gear connection by which the roller is rotated from the main driving shaft of the device while yet permitted to take different positions in relation to disk D. It is this position which in each case is taken as the measurement of the motor speed. The roller gets into this position automatically by following the lines of smallest resistance in its frictional contact with the rotating disk D. The mechanism by which this result is obtained is as follows: The gear wheel R, driven from the main shaft of the device, actuates the wheel R_1, which is guided by the radial arm V, and the latter can turn around the center O_1. R_1 meshes with R_2, which controls the roller G. The arm V is connected by joints, not shown, with the sliding piece E, which is shaped somewhat as a tuning-fork and rides upon the spindle O of disk D. It is upon the unforked portion of this sliding piece that the roller G and wheel R_2 are mounted.

Being thus free to move radially upon disk D, the roller will take the position in which its circumferential speed is the same as the linear speed of the contact point on disk D, in which position there is only rolling friction to impede its movement.

The position of the sliding piece is finally brought in relation to the index hand of the device by means of an arm with a toothed sector, on the plan shown in Fig. 3, the center C of this arm being chosen arbitrarily somewhere near the middle of the curve described upon the disk D by roller G.—From *Bulletin Officiel,* November.

—

DEVELOPMENT of the Schoop Method.—With a view to keeping automobiles and motor trucks, and perhaps especially taxicabs, constantly in commission, looking trim and new in spite of hard service, any process which holds out a promise of serving to keeping vehicles out of the paint shop engages the attention of the public at large as well as of the manufacturer. Among such processes that invented by Mr. Schoop of Zurich, Switzerland, for imparting a metallic surface to objects and substances of the most varied nature by blowing molten metal—especially tin, zinc or lead—upon them, holds a notable place, as it has already been employed in the manufacture of radiators, taking the place of soldering, and has been proposed for other uses to take the place of the electroplating bath, such as for forming water jackets, for coating gear blanks which are to be case-hardened in part and for producing a more substantial nickeling than is usually obtainable by electrolysis (owing to the development of hydrogen at the negative terminal). By the Schoop method as heretofore practiced the object to be coated was placed before a large funnel in which an exhaust fan caused a strong suction, and a spray of the molten metal was blown against the object, being carried in strong current of air or nitrogen taken from a reservoir under high pressure. The excess of metal was drawn in through the funnel and deposited in filters from which it was recovered. Similar methods have been used, at least experimentally, for plastering walls with cement or mortar.

Recently the same inventor has created a very light and portable apparatus which permits operating on any object at any place and without a complicated plant. It is in the nature of an oxy-acetylene gas torch and roughly resembles in appearance a Browning revolver connected by air and gas tubes with small compressor tanks. The flame of the gas torch is projected against the end of a stick of the metal with which the object is to be coated and, instantly melting this metal, carries it into the air, or nitrogen, current which carries it further onto the object, where it immediately cools and solidifies. Nitrogen takes the place of air in the case of metals which oxidize readily. As the cooling is mostly due to the rapid passage of the spray through the atmosphere the tool should be passed before the object at a certain distance from the latter in order to get the best results in each case. A small compressed-air transmission device advances the stick of metal in proportion as the end of it is consumed. Wood, cardboard, plastering, glass and metal can be coated in this manner, and the coating is at once hard and smooth. Its thickness can be varied at will, as the adhesion is perfect.—From *Génie Civil,* December 21.

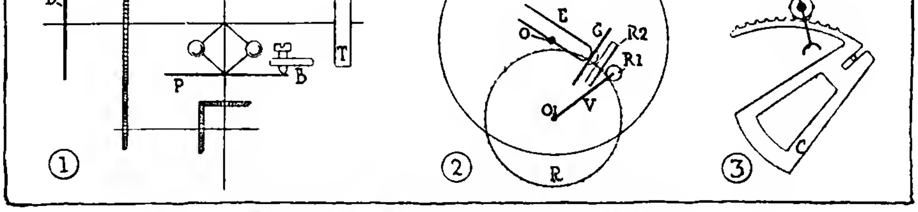
IMPROVED Dustless Road Material.—Coal tar gets soft at high temperatures and brittle at low ones; also slippery. It is therefore not well adapted for replacing the more expensive natural asphalt for road improvements, unless its properties may be changed by some suitable and inexpensive process. By subjecting it to the chemical action of sulphur, imitations of asphalt have been produced from it, but they cost as much as the natural asphalt. Other processes consist in the addition of mineral substances, but the mixture is usually uneven and defective because the mineral substances by reason of their higher specific gravity have a tendency to clutter at the bottom of the mass. Admixtures of organic substances, such as pulverized charcoal, cork powder and sawdust, have resulted indifferently. But it has now been found at the Lindenhof Chemical Works that the tendency to segregation of mineral admixtures can be obviated if a vegetable and a mineral admixture are incorporated in the mass simultaneously. The physical action obtained by this means is that the organic substances coated with the tar resin hold the heavier mineral matter in suspension, and a chemical action is also effected, as the cellulose of the organic ingredients forms viscous compounds with the tar at the temperature at which the mixing is done.

The following is mentioned as a suitable method of proceeding: In a vat with a stirring mechanism 1,000 parts of tar are heated to 150 to 180 deg. C. To this there are added 200 to 300 parts of fine sawdust and 400 to 500 parts of ground chalk. Stirring is continued, without exceeding the temperature of 180 degrees, until the mass is homogeneous. Wood chips or shav-



Figs. 1, 2 and 3—Illustrating principle of Behrens odometer ings may be used instead of the sawdust and marl or ashes instead of the chalk.

The viscous mass obtained can be run into molds and used like paving blocks or can be used directly in road construction. Like natural asphaltum it can be rolled, either cold or hot, into a uniform, coherent and elastic layer, if a firm foundation is provided and heated rollers are employed. The new composition is said to resist wear, heat and cold, undergoing no contraction in cold weather and being always impermeable to water, heat and sound.—From *Revue des Produits Chimiques*, December.

FLASHLIGHT for Grade Crossings.—With the increasing amount of automobile traffic the old method of guarding the grade crossings of railways by means of a bar which is lowered at the approach of trains and from which a lantern is hung at night has proved inadequate; largely, so far as the night traffic is concerned, because the light of the lantern may be confused with other lights which are visible in the line of the street or road further on. Lights flashing 60 to 100 times per minute have lately come into extensive use in the railway signal service, and an adaptation of the same principle is now proposed for grade crossings. The light source in the apparatus offered for this purpose by the well-known Julius Pintsch company (originators of Pintsch gas) is acetylene gas dissolved in acetone and confined in steel bottles. The connection from this bottle, which is at the heavy end of the barrier, to the flashlight lamp, which is at the middle of the bar, as indicated in the accompanying illustration, Fig. 4, is by a single metallic tube, in which the maximum pressure from within the bottle, amounting to 15 atmospheres, is reduced to one-hundredth part of an atmosphere by a reduction valve system rendering the gas pressure uniform in the tube and at a small jet which burns only four-tenths of one liter of gas per hour. This jet is always lit, or may be lighted in the evening and turned off in the daytime, but the light from it is not visible. It serves only to ignite the flashlights, which are produced the moment the barrier is turned around its pivotal bearing to be let down, this movement opening a stopcock sending surplus gas to an intermittent-pressure valve in the lamp which the usual flow of gas to the lighter-flame is insufficient to operate.

Each bottle holds 650 liters of gas which, at the price of 3.50 mark per cubic meter, costs 2.275 mark for each filling. With flashes lasting one-quarter of a second and intervals of one-half second, the daily consumption of the flashes and the lighter is found to average 16.6 liters, at which rate one filling lasts 39 days. This brings the daily cost to 5.82 pfennig or about 1½ cents. Considering this low cost of maintenance, the device may be used both day and night, so as to save the much higher expense which would be incurred by providing for the lighting and extinguishing of the lighter flame. The main objection to the introduction of the device is of course that the railway companies would object to it because if—once introduced—it went out of order and an accident occurred, a suit for damage would be liable to go against them.—From Z. d. M. M. V., Dec. 15.

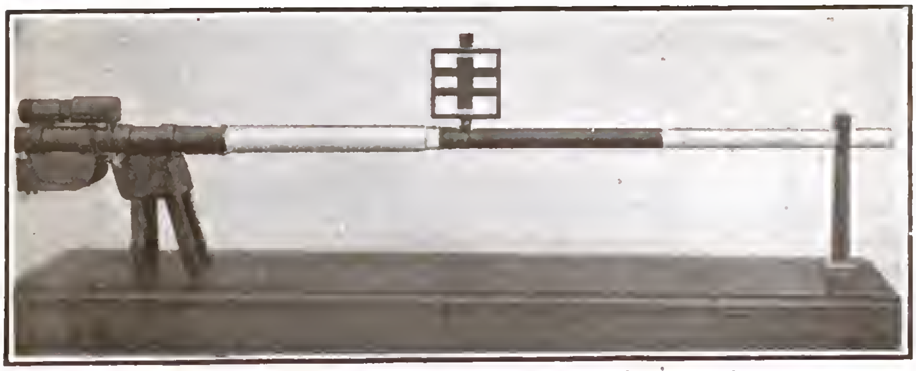

Fig. 4—Sample of flashlight barrier for grade crossings

STEAM Trucks in France.—Among the industrial motor vehicles shown at the Paris Salon last month there were two steam vehicle constructions which surprised many visitors, it being quite generally supposed that the gasoline vehicle had completely downed all competition. These were the Purrey and the Fodens. The Purrey steam trucks are very numerous in France and the power plant used in them, for which coke is the fuel, is the same that is used for the steam street cars in Paris. Their operating and maintenance cost per ton-mile is said to be interestingly low.

The Fodens steam trucks are of a very different type and are made for loads from 5 to 7 tons. They have fire-tube boilers and their engine actuates a flywheel from the shaft of which the power is taken to a differential on the rear axle by means of a reducing gear and a single chain. The low speed gear gives a maximum speed of 5 kilometers per hour and the high gives 11 kilometers. Either of them can be in mesh for starting, owing to the flexibility of the motor power. These trucks are equipped with sheet steel wheels.—From *Omnia*, December 14.

—

Commercial Cost of Radical Change.—The net profits recorded for the firm of A. Darracq et Cie. at the last public accounting were only 18,300 francs, as against 1,824,225 francs the previous year. In order to pay dividends on privileged obligations, 3¾ per cent. on the common stock and the income tax of 500,000 francs imposed in accordance with the new decision of the tax commissioners, the company was compelled to take 1,250,000 francs from the reserve funds. While this unfavorable result of the year's business is in some quarters ascribed in part to the severance of A. Darracq from the company's affairs, the functionaries of the company ascribe it to the expenses incurred in manufacturing its new valveless motor, and they count upon recouping themselves through its success in the future.—From *La Vie Automobile*, December 21.

—

American Engineers to Inspect German Plants.—The American Society of Mechanical Engineers will hold its next summer session in Leipsic, Germany, in common with the Society of German Engineers. About 200 American visitors are expected. It is the plan to inspect the industrial establishments of Hamburg, Leipsic, Dresden, Berlin, Dusseldorf, Krupp, Frankfurt, Munich and Nuremburg. Preparations are already under way for a festive reception.—From *Die Turbine*, December 20.

[The Society of German Engineers is very influential and counts more than 24,000 members. It has a large number of local branches which usually hold their business and social meetings at the most popular local hostelry, frequently under the eyes of the public.—Ed.]

—

Vibrations of Buildings.—With regard to the vibrations of floors, which interfere with the precision of machine work and in some instances with the health of workmen, it has been established through experiments with a seismograph that the operation of a motor in a building constructed entirely of reinforced concrete caused arcs of vibration in two contiguous brick buildings much larger than those observed in the building where the motor was installed.—From *Génie Civil*, December 21.

—

Foreign Car Specifications.—The seventh annual edition of the Catalogue des Catalogues has appeared containing specifications and prices of 2,000 motor vehicles, comprising motorcycles, sidecars, cycle-cars, automobiles, motor trucks and aeroplanes. Lefevre & Baron, No. 1 Avenue Félix-Faure, Paris, send it postpaid for 1.30 francs (26 cents).

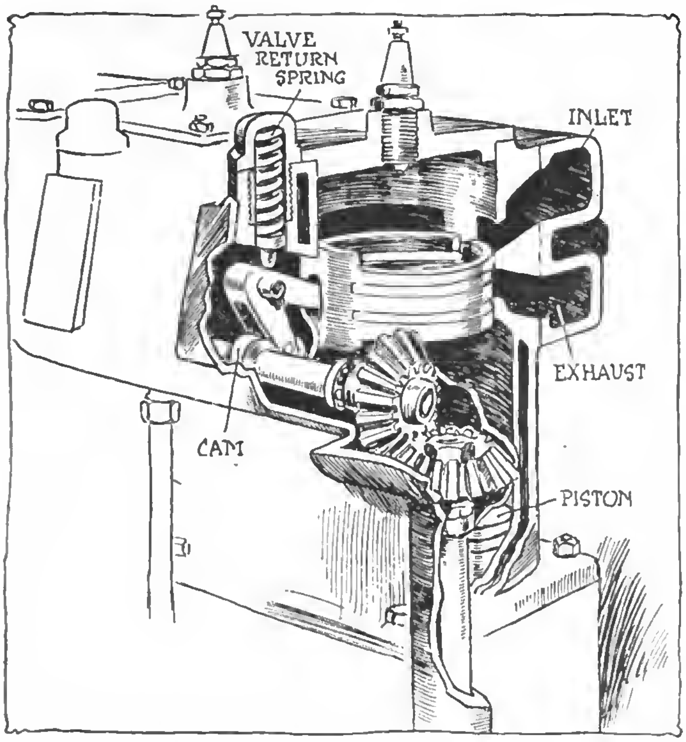

Fig. 18—Sphinx cam-operated sliding-valve motor

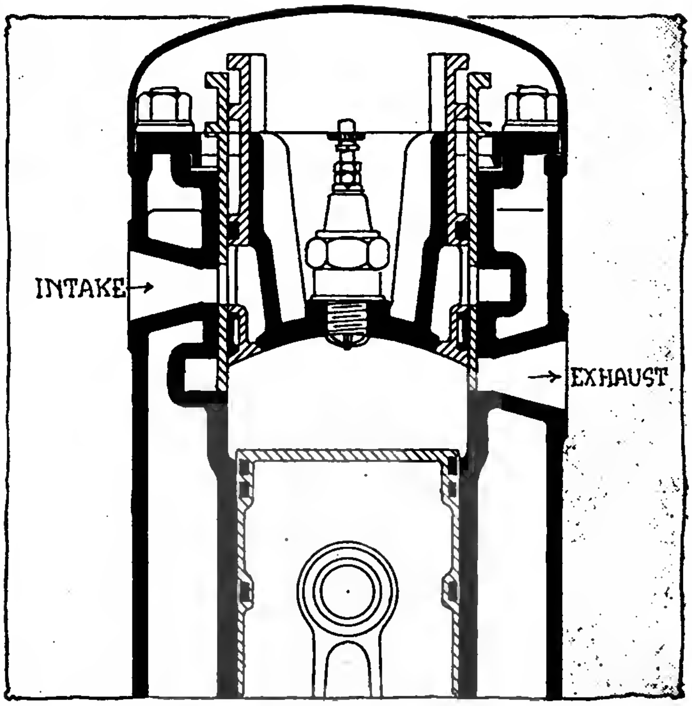

Fig. 19—Overhead sleeve-valve design by Crossley Motors

Criticisms of Non-Poppet Valves To-Date

Cam-Operated Sleeve Valves Have Harmful Effect on Valve-Tappets and Cams, Owing to Strong Return Springs—Laycock Motor Shows Good Scavenging Properties, Resulting in Strong Mixture

Complete Scavenging Produces Quicker Ignition and Combustion—Increase in Thermal Efficiency Over That Obtained with Incomplete Scavenging Should Amount to 25 Per Cent.

By Eugene P. Batzell Installment IV

SOME uncertainty of practical nature is attached to the motor, Fig. 21, in its cam-operated valve. The rest of the design deserves credit, being quite simple in its cylinder and valve construction. The overhead valve operation, permitting a short sleeve for the valve, removes the objections caused by the long sleeves of the type employed in the Knight motor, which objections refer to their manufacture, permanency of shape, lubrication, cooling, etc. The Diehl motor has a sleeve well separated from the cylinder interior, well balanced in regard to pressure and cooled all around. That being the case, the strain on the valve-operating mechanism ought to be small, much smaller than in an overhead poppet-valve arrangement, and therefore there is every reason for expecting a good performance by this motor in practice.

Other designers and inventors also have taken recourse to overhead sliding-sleeve valves with varying success. The Sphinx, Fig. 18, is one of these. This is its second improved form, the first being found unsatisfactory. Even this newer construction leaves much to be desired and in its idea it is inferior to that of the motor, Fig. 21. The slotted-sleeve valve of the Sphinx motor is exposed to the full pressure and temperature of the explosion chamber, the combination of which make sticking very likely, which must have been the makers' experience, because they have discarded the positive means of valve operation, adopting instead a cam and return spring arrangement as used with the conventional poppet valves. The principal advantages of a non-poppet-valve system is its positive valve operation, resulting in always equal valve motion regardless of the motor speed and in the general elimination of the noise, when the mechanism joints are tight. The Sphinx valve being exposed to sticking and also possessing much greater friction in its motion than the conventional poppet valve would necessarily require a very strong return spring if anything like high motor speed is expected with proper valve functioning. The poppet-valve spring must overcome merely the inertia of the valve and the slight friction resistance of the valve stem in its guide. The motion of the Sphinx valve is such that the exhaust port is opened by the cam action overcoming the resistance of the return spring and the friction of the valve against the cylinder walls, which is considerable, due to the valve being split. The return spring is determined also by the inertia and friction of the valve mechanism. The Sphinx valve weight is not less, but rather greater than the weight of the reciprocating valve parts in a poppet-valve motor; besides its valve travel is longer than the lift of a poppet valve. As a result a much stronger return spring is necessary in the Sphinx motor than is used on the ordinary poppet-valve motor, and a more harmful effect on the valve tappets and cams would necessarily follow.

An example of valve design which differs in type from those already dealt with is a recent design by Crossley Motors, Limited, Fig. 19. The principle of the valves should be clear from the drawing, but their actuating mechanism is not shown so that it is impossible to say whether the valve motion is positive or actuating mechanism is not shown because it would permit to state if the valve motion is positive. Another departure from the usual type is the Brasier motor, Fig. 20, which has a main sleeve valve in its cylinder, which directly operates the exhaust, and in connection with a piston valve at the side of the cylinder operates the inlet. These two motors are merely referred to as examples, and as no practical results have been published in connection with either it is only possible to estimate their value from the drawings.

A motor with piston valves has some advantage over the rotary or sleeve-valve type inasmuch as its manufacturing is not rendered more complicated or uncertain on account of the valve system. On the contrary, the piston valve action being identical with that of the main piston there is no reason why equally simple machinery operations should not be proper for both places. Thus the valve mechanism here would be relieved of all the extra precision work which so far has been found indispensable in connection with the sleeve or rotary-valve manufacturing. The tight action of the piston valves being secured with the use of expansion rings no accurate fitting of the valves into their cylinders is necessary, which removes the main item causing trouble in non-poppet-valve systems, that is, heating and change of shape when a permanent good fit is essential. Of course, the piston-valve systems are executed with a great deal of complications in their operating mechanism, losing here in favor of the rotary-valve type. But, all things considered, they could easily prove some advantage over the sliding-sleeve valves, especially in engines where consistency of reliable service is the principal aim. This is apparently proven by the use of piston valves for some aviation motors. Both of these systems are identical in their operating mechanism, but the piston valves have a smaller surface requiring lubrication, they are generally lighter than the sleeves of the Knight type which would reduce vibration and wear in the operating links due to the inertia of moving reciprocating parts; their action is less liable to be affected by the conditions of motor functioning and temperature, etc., all of which tend to make them more reliable than the sleeve valves of the unprotected type as in the Knight motor. The above is not said with the intention of explaining my attitude for or against certain systems; it is based merely on technical comparison between them, and the Knight motor has been mentioned here frequently in drawing comparison merely because it is the most widely known of all the non-poppet-valve systems.

A most promising novelty in valve arrangement is offered in the shape of the piston-valve Laycock motor, Fig. 22. This motor, besides having valves of the variety which are balanced against the cylinder pressure in respect to their driving mechanism, incorporates a feature very little used or advanced in the field of internal-combustion motors, but which nevertheless deserves much attention. This is scavenging of the cylinders from the spent gases remaining there after completion of the exhaust stroke, which gases being mixed with the entering fresh mixture weaken it to a very great extent. There are a few other systems in existence which provide for scavenging, but they do not offer it in a combination of features as in the Laycock, the construction of which is practically not influenced by the added scavenging means and it can be carried out to suit the requirements of every case. Other scavenging systems impose some restrictions in this respect. In the Laycock motor the main cylinder has but a small clearance space at the piston top and the combustion chamber is divided into two parts formed by the space between the two connected pistons of each of the separate inlet and exhaust valves, individual ones for each cylinder. During the upward motion of the valves they draw into the space below their lower piston either fresh air from the outside or mixture though a by-pass to the inlet manifold and carbureter. When the main piston reaches the position, Fig.

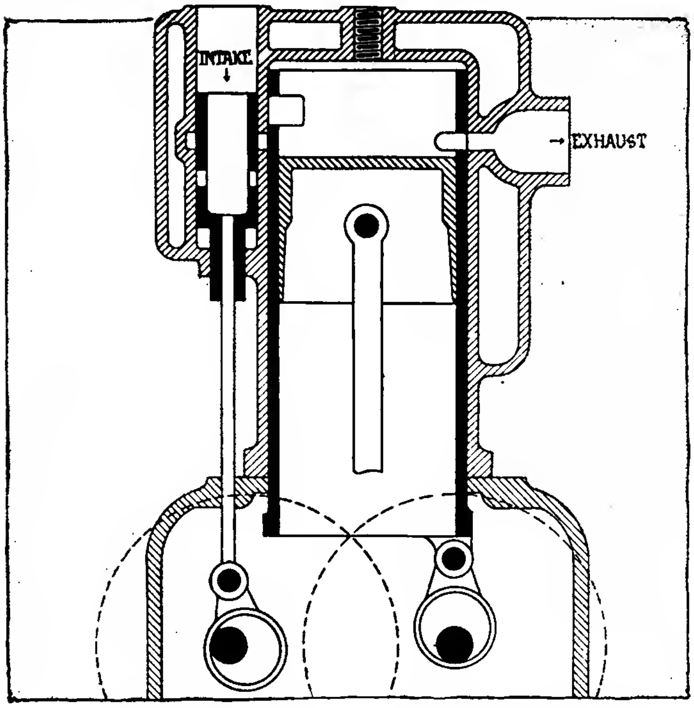

Fig. 20—Brazier motor using sleeve and piston valves

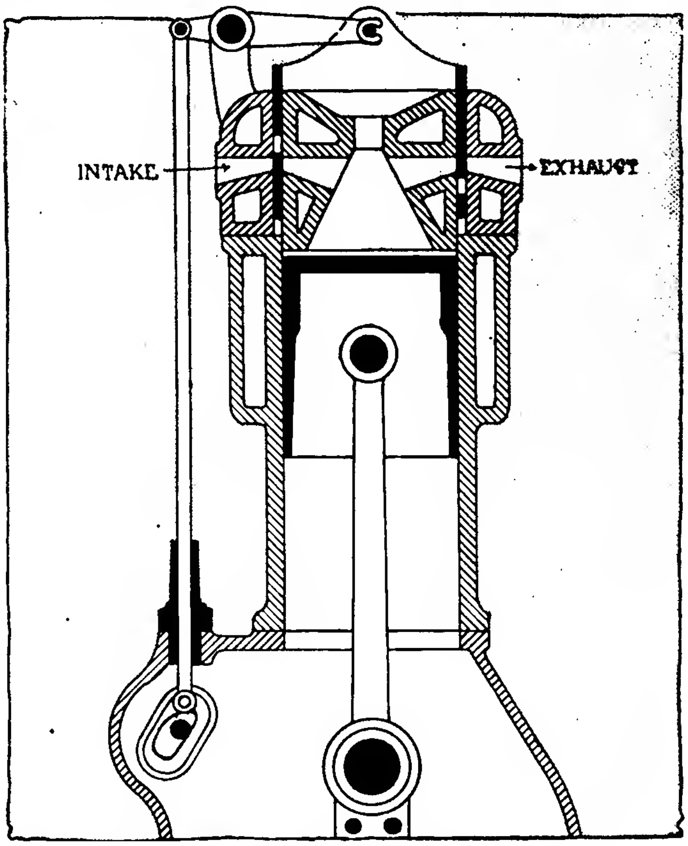

Fig. 21—Cam-operated overhead sleeve-valve of Diehl motor

22, that is, at the end of the exhaust stroke, the inlet valve is about to open the port leading into the cylinder to admit fresh charge from the manifold over the top of the upper valve piston. At the same time the space between its two valve pistons communicates through a by-pass with the compartment below the lower valve piston, the air or gas mixture in which was somewhat compressed during the downward motion of the valve. This air or mixture now rushes into the space between the two valve pistons expelling the spent gases from there into a passage leading outside. The action of the valve and the scavenging of the dividing combustion chambers is identical with that used in two-cycle engines for filling their main cylinder space, and consequently equal results should be anticipated. However, as in this motor only the volume of combustion space is cleared of spent gases the total rate of scavenging, considering also the piston displacement volume, is more nearly complete.

The exhaust valve acts similarly to the inlet valve only in advanced phase according to the timing. The exhaust gases from the main cylinder escape above the top of the upper valve piston, which piston overlaps the cylinder port just before the exhaust begins, thus separating the main cylinder from the space between the two valve pistons. The main cylinder space is cleared of gases by the returning main piston and the spent gases remaining between the valve pistons are expelled similarly as in the intake valves. The ignition of the charge takes place either by a spark-plug located in the main cylinder top or by plugs located in the two parts of the combustion space.

The section of the motor being very simple and identical with that found in other existing and well-proven types there should be little doubt as to its practicability. There are some points, however, about its construction which could be criticized and which would seem to require attention. The separated explosion chambers have an unfavorably large cooling surface through which part of the gain effected by scavenging will be lost. The burning of the charge between each pair of moving valve pistons will necessitate extra requirements for their lubrication because the oil film on the walls of this chamber are liable to burn out. The valve pistons should have lubrication rather from the inside than from oil which is supposed to cover the walls of their chambers. I cannot refrain from approving it in its combination of a simple non-poppet-valve scavenging motor.

Access with a scavenging motor inevitably would mark a big progress in the whole gas-engine field towards greater efficiency of their action. One could obtain high economy without excessive pressures on the working parts and without a mass of complication, which would be inevitable, for instance, when using an engine of the Diesel type to reduce engine of the fuel consumption, obtainable economy by scavenging is considerable and worth much attention. This way to reduce operative expenses of a motor deserves at least as much attention as trials to adopt the motors for cheaper fuel, especially because it can have beneficial influence on the motor action regardless of the fuel used. In my little experience with partially scavenging motors I was surprised to note the results witnessed in respect to the ratio between the explosion and the compression pressures; whereas a ratio of 3 to 1 is considered good in ordinary automobile practice when about 25 to 30 per cent. of the mixture volume is composed of spent gases, reduction of this latter content to about 18 to 20 per cent., but retaining the same rate of compression, was followed by an increase of the ratio between the mentioned pressures to about 4 to 1 and a little over.

The purer charge has much quicker ignition and quicker combustion properties. The absence of late burning results in a steeper expansion curve of the pressure diagram, which approaches the diabatic shape with a pressure volume exponent close to 1.4 instead of 1.3 as ordinarily. Thus relatively lower final pressure and temperature are reached when the exhaust starts. The relation between the higher initial temperature of expression and its lower final value indicate towards an increase of the thermal cycle efficiency amounting to 15 to 20 per cent. for the incomplete rate of cylinder scavenging as observed. Judging from this and as well from statements by recognized authorities a 25 per cent. gain of thermal cycle efficiency can be expected with complete scavenging. Accounting for some losses this theoretical figure might be reduced in practice to show a saving of about 15 per cent. in fuel consumption per power developed. In other words, it could also convey the meaning that with the same cylinder dimensions the scavenging motor would show some 15 per cent. greater developed power. These figures are well worth noticing and they should attract more attention to the scavenging high-efficiency engines than is now given them.

THE END.

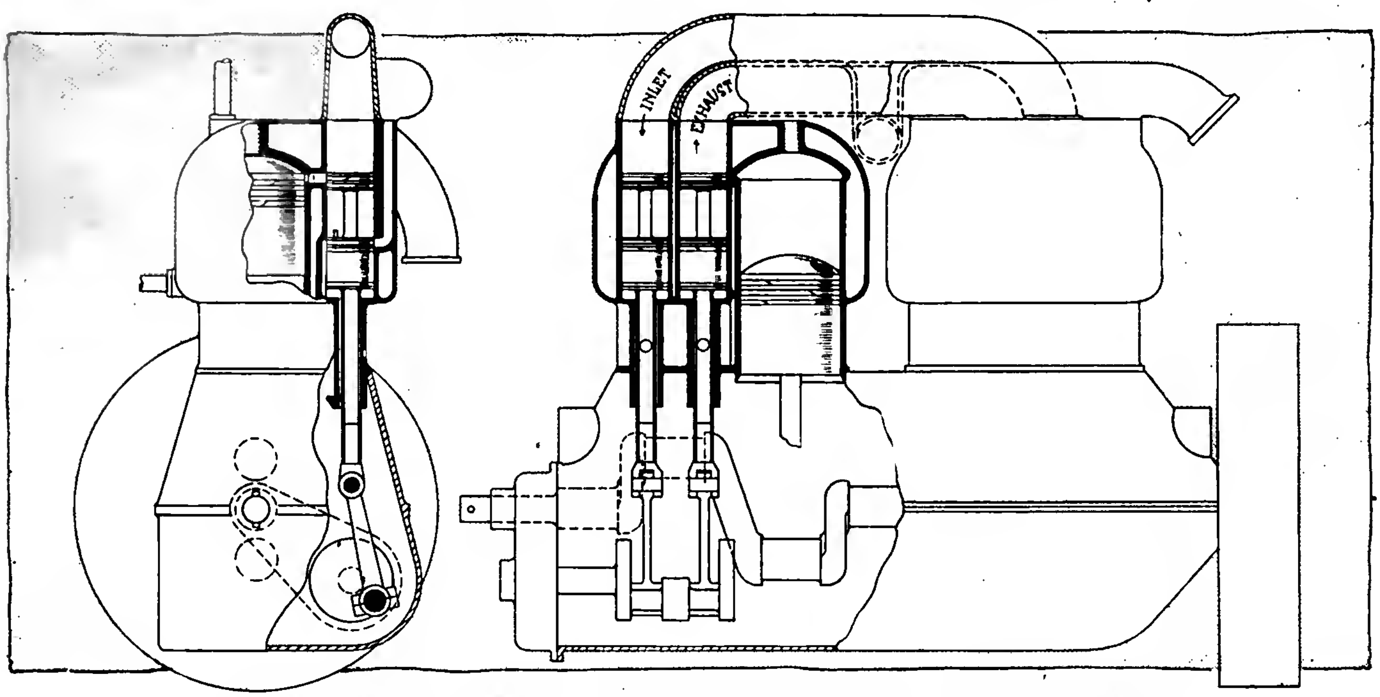

Fig. 22—Sectional views of Laycock piston-valve motor in which provision is made for scavenging

Carburetion

Part V

by Robert W. A. Brewer

Subject Digest

The principal difference between American and European carbureter design at the present time is that the majority of American makers are apparently partial toward the use of moving parts, whereas these are eliminated as far as possible in European practice. The American designer relies upon a suction-operated valve to control the supply of air, while the European pins his faith upon the system of compensating jets.

Controlling factors in the rate of discharge of the fuel from the orifice are the coefficient of discharge from the orifice, the pressure acting upon the orifice and viscosity of the fuel, which varies with the temperature.

Experiments have demonstrated that an increase of the water head above the normal 10 inches slightly increases the fuel discharge up to 16 inches of water head when the discharge increases rapidly.

The type of instrument which has a floating element supported in the air stream and actuated on the one hand by the engine suction and on the other hand by a spring or by gravity has come to the fore very much during the past few years.

CONSIDERING the modern carbureter designs in a broad sense we come to the conclusion that one of **the principal differences between the American and European carbureter consists in the almost general adoption of moving parts in the American design as distinct from their elimination in the European design. What the American carbureter manufacturer relies upon is some manipulation of the air supply by means of a suction-operated valve, whereas the European designer has a leaning towards the system of compensating jets.**

This generalization must only be considered in a broad sense because there are numerous exceptions on both sides of the Atlantic. Taking, for instance, the Holley instrument; this from the writer's point of view shows progress in the European line of thought as moving parts are eliminated and the jet orifice is so designed that under certain working conditions the air is allowed to pass through the jet orifice together with the fuel, thus retarding the flow of fuel when high suction is present in the body of the instrument. Of course, in the American design we have the school of thought which concentrated upon the development of a constant-suction instrument in which naturally a moving part has a very large rôle to play.

Moving parts, in addition to their having a spring-actuated or spring-balanced air valve working against a difference of pressure between the inside and the outside of the instrument, and, as an alternative, the weight of the part itself may be relied upon alone.

Consider for a few moments the controlling factors in the rate of fuel discharge from an orifice, and you find that these amount to the co-efficient of discharge of the orifice and the effective head or pressure acting upon the orifice. The viscosity of the liquid also must be considered, and this also varies with the temperature.

With regard to the question of moving parts, there is only one of these factors which requires our attention, namely, the co-efficient of discharge or jet friction, and we will proceed to consider how this behaves under working conditions with a needle type of control. First—Any orifice must be considered from the point of view of the relation between its area and its length.

Second—With regard to its shape: When the length of the orifice is great with respect to its area we naturally expect to find that the jet friction is greater, or, in other words, the co-efficient of discharge is less than would be the case when the area is greater or when the length is shorter. This we find to be most pronounced in actual practice, as will be shown in the table of figures following, from which it is evident that when the area of the orifice increases beyond a certain amount the characteristic curve of discharge droops, or practically ceases to rise with increments of area of orifice. At the origin end of the curve, that is, where the orifice gets very small with regard to its length, we again find another characteristic of the fuel discharge curve, which shows that when the suction is constant very small increments of area produce very small increase of this fuel flow. However, after a certain critical area is reached the fuel flow for a time increases in a straight line proportionately as the area of the orifice increases.

My experiments on various shapes of metering pins having a straight taper invariably show a characteristic curve of this nature which is somewhat curious. I have, however, found that when the active head has been increased above the normal 10 inches of water for which many instruments are designed, a fuel discharge of a different character takes place. Under these conditions almost the opposite effect has been obtained, namely, when the area of the orifice remains the same, the increase of head has slightly increased the fuel discharge up to a certain value, namely, 16 inches of water head, and after that the fuel discharge rapidly increases in the manner observed with a single round hole.

It will be useful, therefore, for us to consider a few values of flow of fuel in English gallons per hour per square millimeter of orifice with annular orifices of a major diameter of 3.96 millimeters operated on by a pin 24 millimeters in length when this pin is inserted to its full extent in the jet orifice.

Fuel Discharge Through Orifice Under 10-Inch Water Head			Flow of Fuel Through Brewer's Patent Orifice Under 10-Inch Water Head	
Area of Orifice Sq. Mms.	Flow of Fuel in Gals. per Hr. per Sq. Mm	Coefficient of Discharge of the Orifice	Area of Orifice Sq. Mms.	Flow of Fuel in Gals. per Hr. per Sq. Mm.
0.55	1.60	0.924	2.3	0.52
0.86	1.58	0.912	3.1	0.53
1.10	1.40	0.810	3.9	0.55
1.33	1.20	0.693	4.6	0.57
1.74	1.02	0.590	5.3	0.59
2.04	0.95	0.548	5.7	0.57
2.44	0.91	0.525		
3.22	0.88	0.507		
3.90	0.65	0.375		
6.20	0.60	0.346		

Furthermore, in this particular connection, we have the variation which can be caused by a choke tube either altering in its size or in its position with regard to the jet orifice. Taking, therefore, the most usually adopted moving part in American practice, viz., the air valve, we will consider the difficulties in connection with a device of this nature when one attempts to carry out a theoretically perfect carburetion by means of this adjunct.

In the first place, there is the inertia of the valve itself to be considered, and, secondly, there is the spring-error, which is of necessity a feature of all spring-actuated devices, where it is practically impossible to obtain springs of the same nature which can be relied upon throughout their active life.

Springs which are used in connection with air valves are, as a rule, misused, and the more accessible they become the more they are liable to misuse in the hands of the driver or the owner of the car. Furthermore, it is practically impossible on the road to give an accurate adjustment of any spring-actuated device of this sort, although where the cost of gasoline is immaterial, a sufficiently satisfactory result can be, and is, obtained, in ordinary practice. There is, however, a certain period in the working of an instrument, viz., when the extra air valve begins to lift, where carburetion is bound to be momentarily upset due to the very great difference of prevailing conditions when the said valve operates or not, the effect of its lifting being a reduction in the vacuum within the mixing chamber.

It is probably owing to this reason that in carbureters where two springs of different strength are employed, the lighter comes into operation at the initial stage of the valve movement, and its resistance is supplemented by that of a stronger spring as the valve lifts from its seat as the suction of the engine becomes greater.

Now we come to the type of instrument characterized by a floating element supported in the air stream and actuated on the one hand by the engine suction and on the other hand by either a spring or gravity. Such a type of instrument has come very much to the fore during recent years, and it depends for its correct and satisfactory working to a very great extent upon accuracy of manufacture.

When quantity production is carried out, very great care must be taken with the accuracy of any instrument of this type, particularly with regard to the dashpot. Many of these instruments have given unsatisfactory results owing to the dashpot action not being as it should, and the immediate effect of any inaccuracy is that the floating element flutters to such an extent that the instrument absolutely refuses to work.

An instrument of this type in which the action of gravity comes into play has the following characteristics:

1—The inertia of the moving part due to the necessary weight which must be put into it, particularly with the larger sizes of instrument;

2—The effect of this inertia upon the working of this instrument as the car passes along rough or bumpy roads;

3—The liability to leakage of the air, or the effect of air leakage through the joints will naturally alter the depression within the mixing chamber for which it has been calculated; and

4—The leakage of fuel at the stem of the moving part where it is also assisting the dashpot action.

As an instance of the effect of an automatic moving part upon the depression in the mixing chamber of a certain instrument, the following observed values will be of interest: Weight of moving part, 1.5 pounds. Net area of part upon which suction acts, 4.1 square inches. Calculated depression, 0.365 pounds or 9.5 inches waterhead. Engine, four cylinders, 3 9-16 inches by 4¾ inches.

Engine R.P.M.	B.H.P. Developed	Vacuum Inches of Water	Lift of Part in Millimeters
500	8.25	11.0	2.3
1,000	19.5	9.5	4.
1,200	23.4	10.0	5.
1,400	25.9	10.3	6.
1,600	27.2	10.75	6.5
1,800	23.8	11.0	7.5

It will thus be seen that the moving valve regulates the depression with very fair accuracy, at any rate sufficient for all practical purposes.

Harking Back a Decade

FROM THE AUTOMOBILE, January 10, 1902:

A private speedway is being built through the pine woods about a mile north of Lakewood, N. J. It will be 1 1-4 mile long and will be for the exclusive use of members of the association although it is expected that it will be thrown open to the Automobile Club of America. The speedway is to be 80 feet wide. The team to represent America in the international cup race will probably be selected after a series of trials on the course.

Gasoline is now selling in Germany at 40 cents a gallon and lubricant brings $1.24 a gallon.

Methods of timing races used up to the present are inadequate. The famous error in the timing at Deauville last summer and the more recent disputes over times made in the Eagle Rock climb show that 1-5 second may measure the distance between the first and the last in a class of competitors. At 80 miles an hour a car covers 23.5 feet in 1-5 second and as the variation between two stop watches in any given event is rarely less than 1-5 second, the possibilities for error are apparent.

Tests to determine the personnel of the team to represent America in the Gordon Bennett race will be held April 11. The entries are as follows: Alexander Winton, H. S. Harkness, Percy Owen, L. P. Mooers, and C. W. Matheson. Albert C. Bostwick, Windsor T. White and Rollin H. White are prospective entries.

With 140 exhibitors, the third annual automobile show will be held at Madison Square Garden, January 17-24.

A new company to make gasoline engines, headed by Harold O. Smith and capitalized at $50,000 has been started at Indianapolis.

From Last Week's Issue

DEVOTED to the electric vehicle. Wholly electrified up to page 43 inclusive. Mainly descriptive of *status quo* 1912. Fine for reference. Keep it on file.

Did you notice that the power for electric vehicles, including self-starting facilities and lighting, inside and out, does not really cost anything worth mentioning—or at least would not in a socialistic state where only production cost counts—since it is only an off-hour by-product, wanted for no other purpose at the present writing, of the central light and power plant?

Did you notice—on page 23, for example—how boldly electric vehicle makers now place the batteries directly over the rear and front axles, where these supposedly tender mechanisms get just twice as much of a shaking every time a road obstacle is bumped as would be theirs if they were placed midway between the axles? Some argument in this for that silent advancement in battery robustness which distinguishes the vehicle of 1913 from that which scorched its brand onto public opinion way back in 1900—an advancement whose fault has been its silence.

And did you notice the bold and plausible claim made by nearly all contributors from the electric vehicle business, to the effect that no chauffeur is needed for an electric limousine? Quite a saving, if one would otherwise want a chauffeur. But we wonder a little if customers for electric vehicles will subscribe to it; whether it is a water-proof argument or one which will shrink and crock in the wash. The driving and the cleaning of any vehicle is in the long run a prosaic job. while there is poetry in a complete understanding of wonderful mechanism, as well as in several more utilitarian privileges of the owner.

The Car of 1913

THE pendulum is swinging backward. It is swinging backward to lower horsepower; it is swinging backward to fewer models, and it is swinging backward to fewer manufacturers. An accurate survey of the cars listed for 1913 points unmistakably to these facts.

The average horsepower of the various four and six-cylinder models is lower than it was last year, part of which is accounted for by the longer strokes and reduced cylinder bore, which strokes are not considered in calculating horsepower. But if horsepower is neglected and piston displacement taken as the criterion then, too, there is shown a certain reduction, which is chiefly so where new designs are brought out.

But our motors are still large, when contrasted with the European product. Some say we need the extra power because of the bad roads; but granting this there yet remains room for a reduction. When viewed in the horsepower scale the average American car is over 50 per cent. higher than the average European car, these figures being averages of all the listed models, regardless of the output. But we are coming down the scale and if the price of fuel continues to advance there will be some very perceptible reductions in the 1914 models. With the added efficiency that is being obtained from motors by changing valve timing, precluding dust from valve actuating parts, better balancing of crankshafts and reciprocating parts, improved lubrication and lighter-weight moving parts the maker is able to reduce the piston displacement and yet have more power or as much as he had with the larger cylinders.

We are slowly moving to the longer-stroke type. A retrospect over 1911, 1912 and 1913 models shows that the ratio of stroke to bore has been steadily climbing. The steps have been gradual. They are: 1911, 1.14 to 1; 1912, 1.16 to 1, and 1913, 1.22 to 1. This is slow but certain progress. But at this rate we are lagging behind continental practice, and while the average stroke-bore ratio for American cars for this year is 1.23 to 1 the average of the European models is 1.70 to 1. This year has witnessed a big gain and next year will record a still greater one. The square motor is now almost obsolete; it is approximately 5 per cent. of the entire models listed, and those motors under the square are but 2 per cent. of the total.

Nineteen-thirteen models listed record some forward steps that it is difficult to realize. One is the giant stature that the six-cylinder car has attained. There are not fewer than thirty concerns building only sixes. True some of these are obscure ones with small products, but their presence shows the country-wide ramification of the six-cylinder wave of popularity. All told, there are 120 different six-cylinder models.

It is but natural that at the inception of the six-cylinder car the motors should be larger than necessary, but there is a commendable reduction in sizes as compared with last year. There is an average horsepower reduction of nearly 6 horsepower in the average six of this year as compared with that of last year. When we measure the average horsepower of the American six with the average European six we find ourselves 16 per cent. greater, which is a better showing than in the four-cylinder field.

On every hand there are indications of myriads of engineering activities in the present models. Chain-driven camshafts are used by thirteen different companies, and it is certain that next season will witness a landslide to this method of drive, as has occurred across the water. Worm drive has inserted the thin edge of the wedge. Wire wheels are being clamored for by manufacturers, but the difficulty of obtaining them has restricted the listing of them as stock equipment to anything like the extent it is done in England and France. The block casting of motors has progressed by leaps and bounds.

Bodies have profited materially by the activity of the past 12 months. They are a little larger, for the sake of comfort, and the upholstery has been carried to its zenith. Doors are slightly wider.

Left-hand steering has increased to a 25 per cent. following. Larger tires are more general. And last, but not least, while the prices seem to be higher and are from $200 to $400 on the majority of the models, it is due to added equipment, so that the buyer is getting more for his money than he did last year.

Letters Answered and Discussed has been omitted from this issue, the space having been given over to the illustrated review of the year. This popular department of THE AUTOMOBILE will be continued next week.

Parcels Post Opens New Field for Trucks

House Delivery of Packages May Eventually Be Handled by Motor Vehicles—On R. F. D. Routes Efficiency Practically Demands Their Use

CHICAGO, Jan. 6—With the success of the new parcels post assured by the events of the first few days of its use, a new transportation has been born, destined to become a vast system of delivery covering the entire country, handling tons of merchandise a day, delivering house to house in every city and to rural communities, and employing for the work a large number of motor vehicles.

At the present stage of the parcels post the public seems to take it as a new kind of amusement, but with the passing of the novelty will come the serious aspect of increased business facility and a more efficient delivery of medium-sized parcels. It is a possibility that the parcels post system will more than double the amount of matter handled by the government in its mailing systems.

Tests made by the Chicago *Tribune* show that in the majority of cases the mails are quicker than the express companies. The *Tribune* posted twenty packages at 1 minute after 12 o'clock New Year's morning, the moment of the inauguration of the system, these being of various sizes and one to every zone of the parcels post system. At the same moment twenty similar parcels were given to the express companies for delivery to the same addresses. In each package was the request for a wire immediately on receipt of the package.

Out of all the packages heard from seventeen arrived first by parcels post and but three by express.

The list below gives the cities to which the packages were sent, the postal rate and the express rate, these figures giving a good idea of the relative cost of the two systems. Though figured from Chicago, the cost comparison is a fair average.

	Zone.	Express Rate.	P. P. Rate.
Buffalo, N. Y.	4	$0.25	$0.14
Fort Worth, Tex.	5	.25	.09
Milwaukee, Wis.	2	.25	.10
Boston, Mass.	5	.25	.09
St. Louis, Mo.	3	.25	.07
Minneapolis	4	.25	.08
Tampa, Fla.	5	.80	.09
Toledo, O.	8	.25	.07
Fort Dodge, Ia.	4	.25	.08
San Francisco	8	.80	.12
Cincinnati, O.	3	.25	.07
Des Moines, Ia.	3	.80	.12
Washington, D. C.	4	.25	.08
Washington, D. C.	4	.25	.26
Cleveland, O.	8	.25	.17
San Antonio, Tex.	6	.85	.19
Seattle, Wash.	7	.60	.21
Atlanta, Ga.	4	.85	.14
Kansas City, Mo.	4	.55	.14
New Canaan, Conn.	5	.25	.09
Emporia, Kan.	4	.25	.08
		$6.25	$2.48

A test conducted in the East gave the express a slight advantage. A package sent from Washington to the New York *World* by express arrived 27 minutes before a similar bundle sent by parcels post.

A number of enterprising firms used the new delivery for unique purposes, while many took advantage of the new possibilities to play jokes on their friends.

A Gary, Indiana, brick manufacturer deposited 6,000 bricks in the mails, and thereby obtained publicity enough through newspaper comment to pay for many more thousands of bricks.

The first parcel post package was received by President-elect Wilson. A local political club mailed a package of apples to Governor Wilson at midnight. By previous arrangement the regular letter carrier to the Wilson home was on hand and immediately carried the package to his destination by speedy motor car, delivering it to the President-elect at just 12:04.

A nameless brindle bulldog had the distinction of being the first canine that every traveled by post in America. He was delivered by post to a resident of Yonkers.

The first package received at Omaha contained two dozen eggs—nicely scrambled. A coffin was sent through the mails from the Zanesville, Ohio, post office, the cover forming a separate package. It is reported that nearly all of the downtown department stores of San Francisco delivered by parcels post the day of its inauguration.

A horned owl made its appearance at the Chicago post office January 2 en route by parcels post.

It will thus be seen that the possibilities of the new system are wonderful as allowing almost any kind of package under 11 pounds to be delivered. Books are excluded, however. In response to the new system, express rates on many classes have been more than cut in half to meet the government competition.

Packages cannot be deposited in the corner mailbox from now on as formerly. To prevent confusion tags were attached to Chicago package boxes reading as follows:

> **This Box for Printed Matter Only. All Merchandise Requires Parcels Post Stamps and Must Be Mailed at Postoffice or Carrier Station.**

It is probable that the house delivery of parcels will eventually be handled by motor vehicles entirely delivering even on rural free delivery routes.

Program of Business and Social Meetings to Be Held During the New York Show

Association Activities

Monday, January 13.—Meeting of the Executive Board of the American Automobile Association, luncheon 2 o'clock p. m., Belmont.

Jannary 14.—Annual meeting Automobile Board of Trade, 10:30 o'clock a. m., headquarters.

Motor and Accessory Manufacturers, executive committee, 10 o'clock, headquarters.

Motor and Accessory Manufacturers, directors, 3 o'clock, headquarters.

Motor Boosters' Annual Beeksteak Dinner, Murray's Lyceum, 11 o'clock p. m.

January 15.—Society of Automobile Engineers, Standards Committee, 9:30 o'clock a. m., headquarters.

Motor and Accessory Manufacturers. Tenth Annual Meeting, 5:30 o'clock p. m.. Waldorf.

Motor and Accessory Manufacturers, Fifth Annual Banquet, 8 o'clock p. m., Waldorf.

January 16.—Society of Automobile Engineers, Annual Meeting, 9:30 o'clock a. m., 2 o'clock p. m. and 8 o'clock p. m., hallroom, Hotel McAlpin.

Motor and Accessory Manufacturers, directors, 2:30 o'clock p. m., headquarters.

January 16.—Electric Vehicle Association of America, dinner in honor of W. H. Blood, Jr., retiring president, Delmonico's.

January 17.—Society of Automobile Engineers, professional session at hallroom, Hotel McAlpin, 9:30 and 2 o'clock and reception and annual hanquet in Louis XIV dining-room at 8 and 8:30 o'clock.

January 18.—Society of Automobile Engineers, professional session, 9:30 o'clock, at McAlpin.

Social Features

Moon Motor Car Company, January 15, dinner to agents and guests at the Aherdeen.

Cadillac Motor Car Company, January 16, Hotel Astor, dinner to old guard.

Lozier Motor Company, customary dinner, Saturday, January 18.

Overland Company will keep open house throughout the week at the St. George.

Special entertainment will he given for the agents every evening.

Garford Company will maintain headquarters at the Breslin.

The New York Trade Association will hold meetings with the Boston Automobile Dealers' Association and a committee from the association will confer with the National Association of Automobile Manufacturers with regard to the second-hand car prohlem. A luncheon will he given in honor of the Boston dealers, date and place to he announced later.

Locomohile Company of America will exhibit its show cars in the local hranch up to the time of installation at Madison Square Garden.

Packard Motor Car Company has not completed its plans for entertainment hut a rather extensive program will he carried out.

The Peerless Motor Car Company will have headquarters at the Astor throughout the week and will show a chassis in the lohhy. At the Waldorf the Peerless will show an inclosed car.

The Rauch & Lang Company will show a closed car in the lohhy of the Waldorf.

The Winton Motor Carriage Company will give its regular family dinner during the show season, place and date to he announced later.

The Colt-Stratton Company will entertain the Cole agents as usual hut the details of the program have not yet heen framed.

View of the Importers' Salon as the display appears on entering the ballroom of the Hotel Astor from the corridor

Body Work Is Feature at Importers' Salon

Many European Developments in the Coach Builder's Art Shown—Nine Exhibitors Show Fifty-Three Cars and Chassis

THE thirteenth annual exhibition of imported cars now being held in the grand ballroom of Hotel Astor, opened on January 2 and will continue until January 11, the date of opening of the national automobile shows in Madison Square Garden and Grand Central Palace. The exhibit this year is made up of nine European makers, one Canadian and several American body builders. While in number of exhibitors the salon of this year falls somewhat behind that of a year ago, the models shown are representative of the European art and are 1913 productions in practically every case.

The concerns exhibiting are Renault, Panhard, De Dion, Mercedes, Isotta, Minerva, Metallurgique, Lancia and Austrian Daimler from across the ocean and the Keeton from Canada. The body building art is represented by Quinby & Company, Locke & Company, Healey & Company, and the Holbrook Company.

Fifty-three complete cars and chassis are on exhibition, the division being as follows: Limousines, 24; touring cars, 14; runabouts, 2; coupés, 2; landaulets, 7 and chassis, 4.

THE AUTOMOBILE has in its reports of the Olympia and Paris shows, written by its special representatives at these shows, described nearly all of the new models seen as well as illustrated them, and the repetition of another description is unnecessary, excepting where important features of design have been omitted.

The Importers' Salon is always welcomed by the American as it invariably gives new inspiration in body creations, and in this respect the present salon is not disappointing. Two interesting creations are one-passenger cars of the coupé class or the type intended for milady who prefers to go alone when shopping or calling. These vehicles of De Dion and Minerva make are very narrow, the seat being from 42 to 44 inches wide, not possibly allowing room enough for two. The interiors are lavishly finished, the Minerva interior being in hand-carved wood panels, with corresponding luxuries.

There is much versatility in body arrangements for touring cars, one of the leaders being a Metallurgique for seven passengers. The type is a stream-line torpedo. The driver sits in an individual-arm-chair seat, the seat to his left folds against the side of the body and has unusually heavy arm rests for comfort. There are two other folding seats, of the same type. The car has but one door at each side, which is nearly 50 per cent. wider than the conventional ones. There are not a few other examples of the very wide doors for touring-car models. The foreigner has made every effort to keep the rear of the chassis as low as possible and consequently the underslung springs are much more common. Electric lights are nearly general and a special lamp novelty is an Isotta model, in which the fenders are carried on the axles instead of on the frame and each front fender carries an electric bull's-eye. The fenders are very small and the general appearance of the car is considerably changed because of this.

One of the most novel body ideas is the Kellner convertible landaulet on a Panhard-Levassor chassis, which may be used either as a landaulet or as a five-passenger touring car.

The Metallurgique is also distinguished by its efforts in the line of body development. The leader In this respect is the above-mentioned seven-passenger touring car in which there is no partition between the driver's compartment and the tonneau. On this car, the bonnet is shaped with a noticeable convergent flare toward the front, ending in the V-shaped radiator.

The De Dion-Bouton has obtained a novel and pleasing effect by the use of a body border, similar to that introduced by the Alco company, but using instead of a white paint, wicker work along the top edge of the touring body.

One car shown for the first time in New York is the Austro-Daimler. The four motors made by the Austrian company are shown in the several leaders of its line, these being the Prince Henry, Alpine, 1911, and Alpine, 1912 touring body, mounted on 27, 32 and 80 horsepower chassis respectively. Another car on a 60-horsepower chassis completes the line. The Prince Henry type is undoubtedly the most striking representative of Austro-Daimler practice, being fashioned as a stream-line body and with a Metallurgique type of radiator. The other types of body are equipped with straight radiators. All of them are equipped with Bosch two-point ignition, force-feed lubrication and double-bevel shaft drive to the live rear axles. Two sets of brakes are used, the service brakes acting on the transmission shaft and the emergency brakes on the wheel drums. Four speed selective transmissions are used throughout the line of Austro-Daimler cars, and wooden or wire wheels are furnished at the option of the purchaser.

The Mercedes people have made few changes for the 1913 products. The old chassis are being continued, with such minor improvements as a double cone-clutch, a ring-sleeve air valve for varying the air admitted to the carbureter for a given throttle opening and a closer arrangement of the double sets of spark-plugs in their cylinders than has been used heretofore. Furthermore, an air-pressure regulating valve which formerly was carried on the front of the dashboard, is now in place between the latter and the radiator, being thereby made more accessible than before.

The Canadian Keeton car is practically identical with the product built in the United States under the same name. A six-cylinder motor, rated at 48 horsepower but delivering 61 in the dynamometer test and well nigh 70 at the brake, is used in both the seven-passenger touring and the roadster model. The wheelbase is 136 inches with 37-inch wheels in the rear and 36-in wheels in front. A Renault type of hood is used and no starting crank is attached to the front of the car, due to the application of a Jesco electric starter.

Panhard & Levassor exhibit 20 and 30-horsepower cars of the Knight type. In all other respects valveless and poppet-valve motors are alike for both sizes of chassis. The Knight lubrication system has been improved upon by the use of an automatic circulating, non-mechanical oiler working as follows: The oiler consists of a reservoir the outlet of which is governed by a needle valve regulating the passage to the highest crankchamber trough, from which the overflow passes into the next trough and so forth. The oil splashed up by the scoops of the connecting-rod end in the fourth trough returns to the reservoir by its momentum and after being strained is recirculated

Four De Dion chassis, the 10-16, 30, 50 and 100, are shown. The De Dion-Bouton product having been described in a recent issue of The Atomobile, only the chief new features are mentioned here. These are the use of a worm drive between shaft and differential, the standard wire-wheel equipment, Vesta lighting dynamo, set-spark ignition and the carrying under the dash cowl of the gas tank on the 10-16 model. The clean dashboard is a special feature this year.

Renault automobiles for 1913 are built on nine chassis, ranging from 9 to 60 horsepower and equipped with a variety of body styles, including touring cars, limousines and landaulets. Two chassis are also shown. The mechanical developments incorporated in the Renault cars are as follows: The cylinders are offset and the valves are mounted at an angle to the cylinder axes. A Bosch automatically timed magneto is used. The suspension has been developed to an underslung, semi-elliptic system in the rear, instead of the former three-quarter elliptic springs. Renault detachable wooden wheels are standard.

Minerva cars, made in Belgium like the foregoing product, are made in four chassis sizes, namely, 14, 18, 26 and 38 horsepower. The Knight motor has been continued in these cars without changes, and the use of a large bevel gear in driving the differential is the principal mechanical feature. Only the small model uses the worm drive.

The Isotta-Fraschini company is represented by two chassis and several complete cars, every type made by the company being shown. There are six types altogether: the 14-18, 18-25, 25-35, 70-80, 35-45 and 120 horsepower motor chassis, the last two of which have the cylinders cast in pairs, while the others are block castings. The mechanical features of 1912 have been retained for this year.

Two Lancia models, the 20 and 30 horsepower cars, are shown at the Salon. The motors are 3.14 by 5.11 inches and 3.93 by 5.11 inches, respectively. These motors are operated at higher speeds than former models and are cooled by larger radiators. The motor compartment is closed up against the dashboard by an aluminum plate which protects the wooden board from the heat.

Arrangement of the cars at the Importers' Salon in the ballroom of the Hotel Astor, looking toward the entrance

Savannah Gets Big Races

Vanderbilt Cup and Grand Prize To Be Held on Last Year's Course Shortened to 14 Miles

Milwaukee, Determined Not To Be Outdone, Will Make the Pabst Trophy an International Event

SAVANNAH was awarded the running of the next Vanderbilt Cup and Grand Prize races at a meeting of the Motor Cups Holding Company this week. The races will be staged on approximately the same course as in 1911. It is likely that it will be slightly shortened but will be about 14 miles in length.

The races will be run some time between November 1, 1913, and February 23, 1914, but according to Henry Sanderson of the Contest Board of the Automobile Club, of America, it is likely that they will be staged about Thanksgiving Day as usual.

No other applications for the races were formally considered although it was stated that the New York dealers and the Milwaukee Automobile Dealers Association sought to secure the races.

A large delegation from Savannah, representing the local automobile club and various civic organizations waited upon the cup committee and presented the claims of the southern city. Harvey Granger, president of the Savannah Automobile Club was spokesman.

All the details of the Grand Prize race have to be submitted to the Automobile Club, of America while the American Automobile Association has the sanctioning power with reference to the Vanderbilt Cup.

Mr. Granger reported to the committee that the old course is in excellent condition and could be put in shape for the races in 48 hours.

Milwaukee to Run Pabst Anyway

MILWAUKEE, WIS., Jan. 8—Failure of Milwaukee to secure the Vanderbilt Cup and Grand Prize race has led the local automobile enthusiasts to the determination to make the Pabst Trophy race an international event with large cash prizes to be offered. Already negotiations have been opened with the Elgin authorities looking to two race carnivals for August and September.

Tetzlaff Falls Under Official Ban

LOS ANGELES, CAL., Jan. 6—The race meeting just held here will prove of much more interest than the running of the events seemed to warrant because it means the suspension of Teddy Tetzlaff by the American Automobile Association; Barney Oldfield may be permanently barred and a new association known as the Western Automobile Association is in a state of active insurgency against the A. A. A. The Western Automobile Association is at present confined to Los Angeles and vicinity as San Francisco and San Diego so far have refused to affiliate with it.

Tetzlaff's suspension was automatic under the rule that prohibits exhibition and participation in unsanctioned events.

Fiat Wins San Diego Road Race

SAN DIEGO, CAL., Jan. 1—The first San Diego road race, two laps around a course extending through the hills and along the coast, for a distance of 190 miles was won today by Walter Hill in a 120-horsepower Fiat at an average of 57.1 miles per hour.

The finish was at Pacific Beach and Hill finished 10 minutes ahead of Smith in a Mercer. Considering the mountain grades and the winding road, Hill's time of 3 hours 59 minutes and 36 seconds was very fast.

Hardly less remarkable was the showing of W. H. Smith and his little Mercer. W. H. Carlson, Jr., driving the Stutz No. 20, after he had been given up as out of the money, came to the front and won third place. Smith's time was 4 hours, 12 minutes, 12 seconds; Carlson's time was 4 hours, 16 minutes, 15 seconds and Louis Nikrent, Buick, who came in fourth, made it in 4:48:09.

Broken springs and radius rods were mainly responsible for Bob Burman's failure to place. Spider Campbell had engine troubles and quit at the finish of the first lap. C. A. Conant's National went into the ditch at Encinitas on the first lap and broke a wheel. Al Lambis, in a Columbia, was thrown out of the running after finishing the first lap. The steering gear gave out on Torrey Pines grade.

More than 100,000 people lined the sides of the road on which the machines traveled.

Galveston to Offer $25,000 for Races

GALVESTON, TEX., Jan. 6—Plans for what is already assured of being the biggest automobile race meet ever held in the south, with cash prizes totaling $25,000, are well under way under the leadership of Captain J. W. Munn, chairman of the Beach Course Race committee of the Fifth Annual Cotton Carnival. The plans which have been set in motion are sanctioned by the Galveston Commercial Association and have also been indorsed by the most prominent business and professional men of the city.

The big race meet will be held in August during the Cotton Carnival days, tentatively set for August 7 to 16 inclusive, during the 10 days of which there will be 5 devoted almost exclusively to the automobile races, the races being held every alternate day of the 10, as it is thought the best results and attendance can be secured in this manner.

Now that everything is in readiness for announcing the dates and events of the race, Captain Munn has inaugurated a movement which should result in the establishment of a permanent fund for automobile races at Galveston. He with his committee secured enough money to erect a long string of permanent grandstands and seats, also have fenced off the 5-mile straightaway race course and have prepared 5 additional miles so that 10 miles straightaway may be run if desired.

Two Stutz Cars in 500-Mile Race

INDIANAPOLIS, IND., Jan. 6—To the Ideal Motor Car Company, of this city, belongs the honor of making the first entries for the 500-mile sweepstake to be held on the Indianapolis Motor Speedway, Memorial Day. Two Stutz cars have been entered and Charles Merz and Gil Anderson nominated to drive them. Anderson and Merz are two of the most consistent drivers in the racing game and have made an excellent showing with Stutz cars wherever they have driven.

The Speedway management has announced that the prizes for the 500-mile event will aggregate $50,000, the same as last year, but that they will be divided among ten drivers instead of among twelve drivers as in 1912. The prizes will be as follows: First, $20,000; second, $10,000; third, $5,000; fourth, $3,500; fifth, $3,000; sixth, $2,200; seventh, $1,800; eighth, $1,600; ninth, $1,500, and tenth, $1,400.

Paul R. Martin has been appointed general press director of the Indianapolis Motor Speedway and of the Ocean-to-Ocean highway movement. He succeeds Homer McKee. Mr. Martin came to Indianapolis 5 years ago.

A Correction—In the description on page 113 of the Correja car it should be stated that this company will make only sixes. The bore and stroke of the motor described should be 4 by 6 inches. An Eisemann magneto, electric lighting and starting and full equipment are among the prominent features.

Gotham Raises Limit

Aldermen Pass Ordinance Increasing Maximum Speed Permissible in the City to 15 Miles An Hour

Penalties Provided Are Severe, Being Graduated as to Number of Offenses—Owners Responsible

INCREASING the speed limit for automobiles to 15 miles an hour and increasing the penalties for violation, the aldermen of New York have passed an ordinance doing away with the ancient law that made 8 miles an hour the speed limit in New York. On certain much used automobile thoroughfares of Harlem and the Bronx, the limit is set at 18 miles an hour. In certain highways in Brooklyn and Queens 20 miles and in outlying sections 28 miles. The old law has been a dead letter almost from the time of its enactment and much uncertainty existed in the minds of the general public as well as automobilists as to traffic rights.

Offenders are to be punished on a graduated scale. For first offense the penalty is a fine of $25 to $100 or 15 days in jail, or both; second offenders within a year, fine $50 to $100. or 30 days or both and for third and subsequent offenses, $100 fine or 60 days or both.

Owners riding in automobiles at the time of breaking the speed law, are deemed liable to punishment provided for misdemeanors.

The law goes into effect March 1. The vote upon it was unanimous.

Fire and police automobiles, United States mail vehicles and ambulances are excepted from its operation.

Gramm Output to Be Increased

LIMA, O.. Jan. 6—At the annual stockholders' meeting of the Gramm Motor Car Company, of Lima, Ohio, which was held recently after being postponed from September 10. steps were taken toward increasing the output of the plant to a large degree. It is planned to build 5,000 trucks during the coming year and to bring about that change it will be necessary to employ 700 men instead of 275 as at present. Additional space will be secured.

The announcement has been made that Thomas M. Conroy, of Elmira, N. Y., has been made superintendent in the place of Michael Coakley, resigned.

Officers elected were: John N. Willys, president; G. W. Bennett. vice-president; J. E. Kepperly, secretary; Walter Stewart. treasurer; J. N. Garver and H. K. Hocke, general managers.

W. A. Redding Signally Honored

William A. Redding, chief patent counsel of the Automobile Board of Trade has just been elected president of the General Alumni Association of the University of Pennsylvania which has a membership of about 20,000. The university ranks as third in the United States. The new president has announced that he is in favor of forming a cohesive body, including all graduates of the institution, to exert a powerful influence for progress throughout the world.

Marvin Explains Purpose of Branch

DETROIT, MICH., Jan. 6—That the branch office established in the Ford building. Detroit, by the traffic department of the National Association of Automobile Manufacturers will aid automobile manufacturers to get cars through to their destination promptly and secure their return, is the statement of J. S. Marvin, of New York, general traffic manager for the N. A. A. M.

"When a manufacturer sends a car out on one road and the car must be turned over to another road before reaching its destination, we will beat the car and notify the second road that it is coming and to be ready for it," said Mr. Marvin. "We intend to keep after roads in the matter of rates the same as we have been doing for years. It is hard to get special automobile cars, although there are 45,000 or 50,000 of them in service. The reason is that automobile cars are used by manufacturers in other lines.

"It is rather queer, but it seems only a few days ago we were asking the railroads for special automobile cars, and now there are nearly 50,000 of them. At that we could use more. The Detroit office will have very little, if anything, to do with Detroit traffic congestion. We will leave that to the board of commerce, whose traffic department is handling the matter. We needed a branch office in the West and Detroit was the logical place."

Mr. Marvin announces that he will divide his time between the New York and Detroit offices. R. A. Gardner has assumed charge of the Detroit branch, coming from the Stoddard-Dayton company.

Lion Assets Bring $12,500 at Sale

DETROIT, MICH., Jan. 6—Referee in Bankruptcy Joslyn has effected the sale of the factory equipment of the Lion Motor Car Company, of Adrian, after the sale had been postponed twice on account of low bids.

The property goes to Samuel Winternitz & Company, of Chicago, for $13,000. At the first sale the highest bid was $7,000, and the second time it was offered Winternitz & Co., bid $12,500, raising their own bid the last time the property was offered. Attorney Charles L. Robertson was named as trustee in the proceedings.

The tangible property was appraised at $33,401.73. The various claims presented against the company when business was suspended amounted to $108,000. The actual amount of liabilities outstanding are estimated by Attorney Robertson at about $75,000.

Engler Heads G. M. T. Engineers

DETROIT, MICH., Jan. 6—W. B. Engler, for the last 3 years head of the engineering department of the General Motors heavy-duty gasoline truck plant at Owosso and previously with the Olds Gas Power Company, of Lansing, Mich., has been promoted to the post of chief engineer of the General Motors Truck Company, with entire charge of experimental and development work. The announcement is made by W. L. Day, vice-president of the company.

Mr. Engler has spent the last 3 months abroad in preparation for his new position, most of the time being spent in England, Switzerland, Italy and France.

Ricker Enters Broader Field

INDIANAPOLIS, Jan. 6—Chester S. Ricker, chief engineer of the Henderson Motor Company, has resigned to enter the field as a consulting engineer. He has been retained by the Henderson company in an advisory capacity. Mr. Ricker designed the six-cylinder model put out by the company and has recently completed an electric starter.

Castle Out of Lamp Company

CINCINNATI, Jan. 6—Fred E. Castle, who resigned the presidency of the Castle Lamp Company recently, has announced that he is not connected with the company in any way. Mr. Castle stated that his plans for the future have not been definitely formed.

$7,000,000 For U. S. M.

Reorganization Committee Bids That Sum For Assets of the Company and Court Will Rule by Friday on Offer

Flanders To Head Standard Motor Company, Which Will Take Over and Enlarge Old Concern

TWO bids, one for about $7,000,000 and the other to pay a percentage of the indebtednesses of the United States Motor Company and its subsidiaries, were made in the United States District Court on Wednesday. Judge Charles M. Hough received the bids and announced that he would rule which, if either, of them would be accepted by Friday.

The bidders were Henry C. Holt and William McAlister, acting for the reorganization committee. If one of the bids is accepted the property will be transferred to the Standard Motor Company, a Delaware corporation of which Walter E. Flanders will be president and W. J. McGuire, vice-president.

The receivers reported that the losses incurred in manufacturing since they took hold were $308,000 and that all the factories are closed as far as new work is concerned except the Briscoe Manufacturing Company. The Atlas Engine Works gave notice that appeal would be taken from any order of sale, but this will not serve as a stay to the proceedings.

INDIANAPOLIS, IND., Jan. 6—There was a new turn in the affairs of the Maxwell-Briscoe Motor Company, and the United States Motor Company last Friday when the Indiana creditors of the Maxwell company asked that that concern be adjudged bankrupt, the petition being filed in the federal court in this city. These same creditors filed a petition in the superior court here recently asking that the Newcastle plant be sold separately from the other Maxwell plants.

Franklin Raises Its Capitalization

SYRACUSE, N. Y., Jan. 6—The capital stock of the H. H. Franklin Manufacturing Company was raised from $300,000 to $1,500,000 at a meeting of the stockholders held Friday, January 3. The new stock consists of 9,000 shares of common stock of par value of $100 each and 6,000 shares of preferred stock, 7 per cent. accumulative, of par value of $100 each.

The increase in the common stock is made by a 200 per cent. stock dividend upon the present capital stock.

American-La France Refinancing

Additional capitalization for the American-La France Fire Engine Company has just been announced. The old company was capitalized at $2,900,000, divided into $900,000 bonds; $1,000,000 preferred stock and $1,000,000 common. It was found that the company required more working capital and a new issue of $2,000,000 of 7 per cent. cumulative preferred and $1,450,000 common was authorized to take up the old issues. The bonds will be retired from the proceeds of the sale and the floating indebtedness has already been liquidated from earnings.

Bill Heads Rambler Sales and Plant

KENOSHA, WIS., Jan. 6—(*Special Telegram*)—Important addition to the executive staff of Thomas B. Jeffrey Company, manufacturers of the Rambler, and promotions among prominent employees were given out today by President Charles T. Jeffrey.

Louis H. Bill, who for many years has had charge of the Pacific coast business, has been appointed assistant general manager in charge of both factory and sales. Mr. Bill was prominent in the bicycle industry and for the past 10 years has been actively identified with the automobile business on the coast. Harry E. Field, who formerly had in his charge the business of the company in New York and adjacent territory, becomes general sales manager with George H. Cox as his assistant. Field was formerly vice-president and general sales manager for the Hartford Rubber Works.

J. W. DeCou, is factory manager, while John Bjorn has been made assistant factory manager and general superintendent.

Two assistant superintendents have been appointed, including George N. Bliss, and M. Mattson.

Three general foremen have been named: William Martinson, C. P. Heide and H. Luthi.

The new officers of the company include president, Charles T. Jeffrey; vice-president, Harold W. Jeffrey; second vice-president and treasurer, George H. Barry; secretary, Edward S. Jordan and assistant secretary, Edward S. Haddock. The Jeffrey Company is the outgrowth of the old Gormully & Jeffrey Company

New Manager for Herreshoff Plant

DETROIT, MICH., Jan. 6—C. Stuart Somervell, until recently manager of the Lycoming Foundry & Machine Company, of Williamsport, Pa., manufacturers of automobile motors, has become general manager of the Herreshoff Motor Company, of Detroit. Mr. Somervell will perform a part of the duties hitherto falling to Charles F. Herreshoff, chief engineer and vice-president, the office of general manager being a new one.

Rubber Steadily Lower in 1912

During 1912 the price of the highest grade of crude Para rubber ranged between $1.22 and $1.01, the final quotation of the year was $1.09. Since 1909 something over 1,000,000 acres of rubber has been planted in the mid-East. Only a small propor-

Automobile Securities Quotations

Prices yielded slightly during the past week, due largely to the fact that the eyes of investors were turned toward the general market. A few of the specialties were higher but trade was small in volume. The feature of the trading was the strength displayed by Goodrich and the firmness of General Motors, Alco and Pope. Otherwise the market was pretty soft in spots. The automobile specialists were waiting for the sale of United States Motors and the developments to be announced following the sale.

tion of this tremendous cultivated acreage is in the productive stage at the present time.

The plantations turned out 28,000 tons of rubber during 1912, approximately double the yield of 1911. Taking the natural percentage of trees that will come into bearing in 1913 and the natural increase of yield in the plantations already producing, it has been estimated that the cultivated rubber yield of the present year will not be far from 55,000 tons.

Automobile tire requirements for this year represent about the total rubber production of the world 15 years ago.

Col. Samuel P. Colt, president of the United States Rubber Company, states that the past year has been generally favorable for the tire makers. The spring business was poor on account of bad weather and a backward season, but the fine weather conditions of the fall evened the score.

Gasoline Still Making High Records

Wholesale prices of gasoline have been steadily advanced during the past year. Starting with the wholesale rate at 9 cents, the first few days of 1912 saw the price pushed up to 11 cents. Since that time the price has been advanced cent by cent until now a new high mark of 17 cents has been established.

This makes the retail price at least 20 cents, and from that level it ranges as high as 30 cents. Much irregularity was noted during the year as between various sections of the country. This is accounted for by the fact that quite a large number of contracts covering portions of the year had been made between wholesalers and the oil companies. With a very few exceptions these contracts have now expired and a more uniform, if less agreeable, condition obtains.

The oil companies declare that the law of supply and demand is working in the gasoline field, while the enormous advance in the price of oil securities and the tremendous dividends paid on these stocks is viewed with much interest by the consumers.

Market Changes for the Week

There was a pressure for steel in all sections, consequently there were freer offerings in the metal markets. Tin was heavy, weak and lower in the domestic market on Tuesday, with freer offerings at concessions of 15 to 20 points early in the day. Tin suffered a loss of $.45. Copper electric and lake declined $.00 1-8. Cottonseed oil rose $.06. In the chemical market, gasoline rose $.01 1-4, petroleum $.05, and lard oil $.02. Tire scrap, antimony, Bessemer steel, open-hearth steel, sulphuric acid, cyanide potash, fish oil, and Kansas petroleum remained constant throughout the week.

U. S. Exports $2,107,721

Thirty-One Commercial Cars to a Value of $56,176—1,658 Passenger Cars to a Value of $1,750,890

Imports from the United States Have Steadily Risen During the Past Few Years

WASHINGTON, Jan. 6—During November, 1912, domestic exports of automobiles and automobile parts, not including engines and tires, from the United States amounted to a total value of $2,107,721. The exports were divided as follows:

Thirty-one commercial cars of a value of $56,176; 1,658 passenger cars of a value of $1,750,890, and parts of, $300,655.

Consular and trade reports received by the Department of Commerce and Labor continue to discuss the excellent field abroad for the American made motor machine. The American consul at Johannesburg says an especially good market for motor cars will be found at and around that city.

"While England still continues to sell most of the motor machines in that district," says the consul, "the imports of automobiles from the United States have steadily risen during the past few years and would, in the opinion of many, be much greater but for the fact that the prices charged the local agents by certain American firms having the exclusive handling of the machines in this country have been considerably in excess of the manufacturers' prices."

The consul continues:

"The imports of motor cars and parts into the Union of South Africa in 1911 amounted to $1,800,495 in value. Of these the United Kingdom furnished machines to the value of $1,172,549; United States, $208,000; France, $166,997; Germany, $147,784; Canada, $81,600, and Belgium, $15,878. The total from all countries is an increase of $400,000 over 1910, and the 1911 imports from the United States show an increase over 1910 of more than $50,000. The 1911 imports from the United Kingdom were $358,803 in excess of 1910. Both Germany and France show substantial decreases, while Canada increased its sales from $6,389 in 1910 to $81,600 in 1911. These Canadian sales are of a well-known American car (Ford) manufactured at and shipped from a branch factory in Canada."

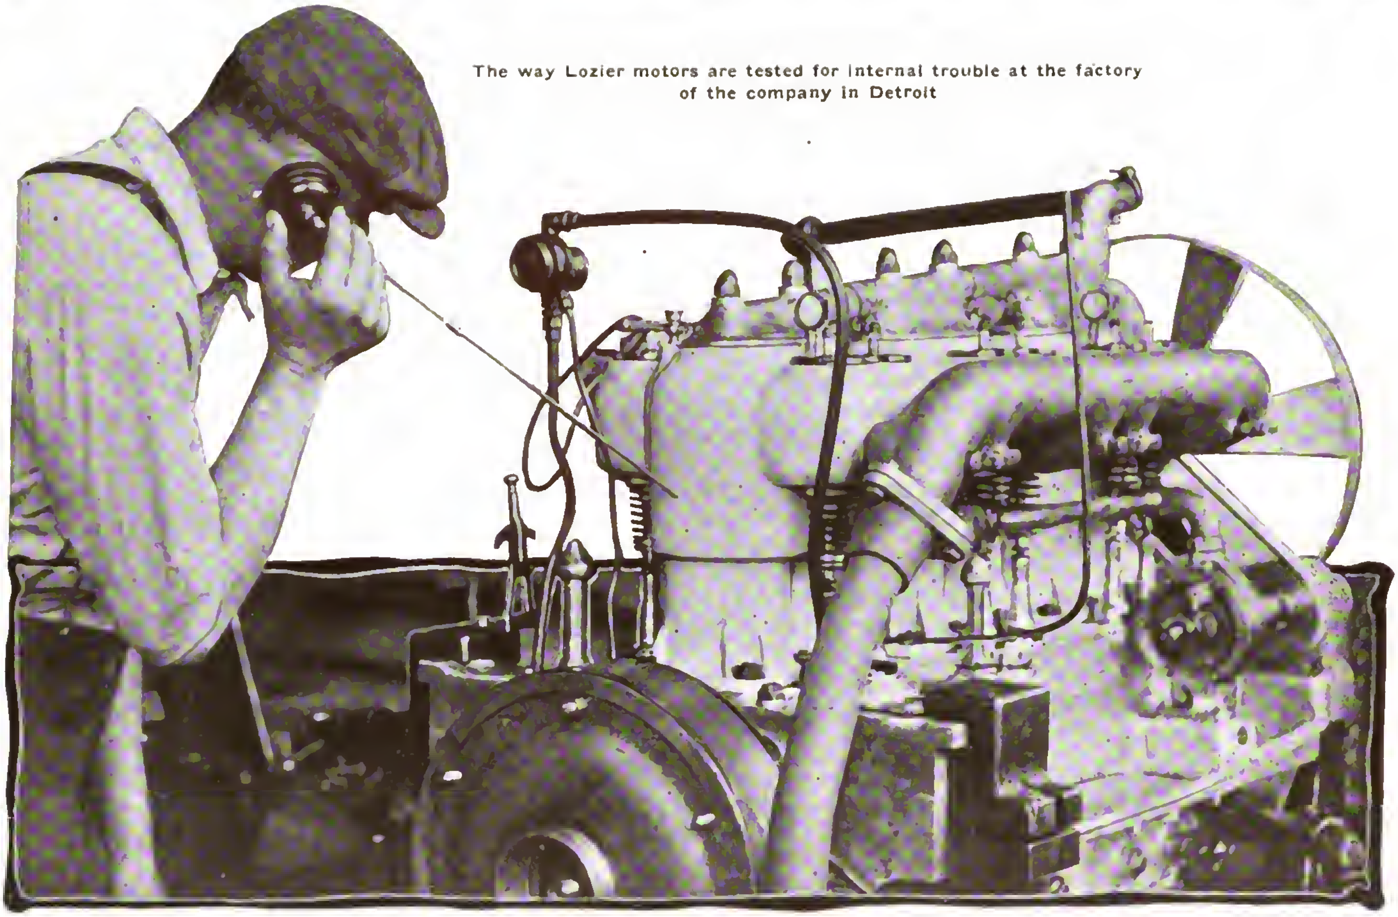
The American Consul at Sheffield says the use of the automobile is becoming more general in that city, and there is no reason why American manufacturers should not secure a share of the growing trade. He says there are a number of American

The American consul at Huddersfield says:

"The sale of American motor cars is rapidly increasing and the outlook for the future is good. The total registered motor cars in Huddersfield at the beginning of 1912 was 663. Of these 595 were pleasure cars and 68 were used for commercial purposes. The retail prices of the different grades selling range from about $730 to $4,150. The retail prices of cars most largely sold range from $2,430 to $2,675, complete. The horsepower employed is generally 12 to 20. The four-cylinder car, 14 horsepower, is popular. It is estimated that about 150 cars are sold in this district annually. Of this number probably 50 per cent. are French. A few of these are imported direct by way of the ports of Hull and Goole, but as this trade is chiefly carried on through general agencies the bulk of imported cars reaches this district indirectly.

"An effective method for advertising American goods and the efficiency of modern American manuacturing methods was a series of lectures, accompanied by motion-picture illustrations showing the various processes in motor-car production, given by a representative of a Michigan establishment. The lectures were held in one of the principal halls of the town."

Factory Miscellany



The way Lozier motors are tested for internal trouble at the factory of the company in Detroit

THERE is no marked similarity between the physician's office of a life insurance company and the block testing room of a motor car factory, yet they have points in common. Among the tests given in each place is that of the stethoscope. The physician uses it to detect irregularities of the heart, and the mechanic to discover any uneveness of operation in the motor.

While it serves the same purpose as the stethoscope, the instrument used in the high grade motor car factories is slightly different in appearance. It consists of a steel rod made of three separate pieces combined with a regulation telephone receiver. By placing the end of the rod against the side of a motor it is possible to locate the source of the smallest disturbance. The lightest of "valve slaps" or knocks in the engine are thus noted, allowing the correction of any fault before mounting the motor on a chassis. The road testers carry similar instruments as an extra precaution against the possibility of car being turned over to the sales department with a faulty motor.

The accompanying photograph taken in the Detroit plant of the Lozier Motor Company, shows a workman testing the exterior of a six-cylinder motor for interior trouble. In the same manner the entire car and running gear can be examined.

TIMKEN'S Glass House—The Timken Roller Bearing Company, Detroit, Mich., is building a new factory for the grinding of the cups, cones and rollers. The dimensions of the new Timken plant are 64 feet by 240 feet. It is of the latest saw tooth skylight roof construction and $100,000 of new machinery will be installed. The accompanying photograph conveys the impression it is a conservatory for tender young plants but in this instance it is, in truth, the half-clothed skeleton of that plant.

Fitzsimmons Erecting Factory—An automobile factory costing $12,000 is being erected in Lindsay, Ont., for J. A. Fitzsimmons.

Summers Establishes Factory—Summers Brothers, Glasgow, Ky., will establish a factory in Indianapolis, Ind., to manufacture a hydraulic transmission for automobiles.

Factory at Louisville—The Speedway Tire Company, incorporated under the laws of Kentucky, with a capital of $250,000, will build a factory in Louisville in the near future.

Scharf Gearless Builds—The Scharf Gearless Motor Company, Richmond, O., incorporated for $10,000, by G. W. Worden and others, will erect a plant to make a new gearless motor.

Brass Works on Fire—The Port Washington Brass Works, Port Washington, Wis., owned by John Meyer, sustained a total loss by fire due to defective wiring. The works will be rebuilt without delay.

Walloff Factory in Redcliff—It is stated that the Walloff Motor Company, of Minneapolis, Minn., has decided to establish a factory in Redcliff, Alta, and will commence work on the erection of a plant immediately.

Another Franklin Meeting.—A conference of the Franklin Automobile Company, Syracuse, N. Y., dealers of the Pacific Coast, Cleveland and Cincinnati, O., districts, will be held at the Franklin factory on January 10.

Wolverine Accessories Plans Factory—The Wolverine Motor Supplies Company, Detroit, Mich., manufacturer of automobile accessories, has had plans prepared for a two-story brick addtion to its plant, to be 74 by 84 feet.

Oldsmobile Factory Inspected—During the holidays the branch managers of the Olds Motor Works, Lansing, Mich., throughout the United States were invited to attend a meeting at the factory for an exchange of opinions on the past policies of the company and to assist in forming new features in the conduct of the business for the coming season. The most noteworthy event of the meeting was the concerted inspection and criticism of the new light Oldsmobile Six.

Jan. 17..........New York City, Banquet, Hotel McAlpin, Society of Automobile Engineers.

Race Meets, Runs, Hill Climbs, Etc.

May 30..........Indianapolis, Ind., 500-Mile Race, Speedway.

Building $100,000 Plant—The Canadian Standard Automobile & Traction Company, with a capital of $250,000, is calling for tenders for the erection of a factory at Moose Jaw, Ont. The factory is to be 250 feet by 50 feet, its value with the machinery and plant being $100,000.

Moon Installs New Machinery—The Moon Motor Car Company, St. Louis, Mo., recently installed a considerable amount of costly new machinery in its rear axle department. The Moon rear axle department is now equipped to turn out a new rear axle evrey 20 minutes.

Palmer-Moore Leases Plant—The Palmer-Moore Company, Syracuse, N. Y., has started the manufacture of a truck with a 2-cycle motor with throttle control and with a capacity of 1,600 pounds, has leased the plant formerly occupied by the Syracuse Stove Works in North Geddes street, and will move in the early part of January.

McNaul Tire Moves—The McNaul Auto Tire Company, Toledo, O., has moved into a three-story brick building on Superior street, formerly occupied by the Merrill Company. The place is being remodeled and redecorated. The McNaul company manufactures a tire which is practically puncture-less and has outgrown the old quarters on Cherry street.

To Build Wizard Plant—P. S. Florea, O. C. Forbes and E. H. Habig, Indianapolis, Ind., have organized the Wizard Motor Company, which has been incorporated with an authorized capitalization of $50,000. A factory is to be leased immediately, and motors adaptable to cycle cars will be manufactured. J. L. Yarian has been engaged as factory superintendent, engineer and designer.

Plan Automobile Factory—A project which is now on foot, in which some Coshocton, O., people are interested, may result in the establishment of an automobile factory in that city within the near future. It is planned to use the old Premium Manufacturing Company building and there to assemble cars, the parts of which will be made at other points. Indiana parties are interested in the deal and J. C. Baughman of that city is taking care of the local end of the planning. The company expects to make cars valued at $2,000 and $2,500, and to assemble them.

How Moon Tests Motors—Whenever an engine is put on the testing block in the Moon Motor Car Company's factory, St. Louis, Mo., it is directly connected by means of coupling to another engine which is running under its own fire; the engine under fire drives the engine which is being worn in until the latter is in position to work under its own fire when dynamometer tests are made and the engine which passes the inspection test goes to the chassis assembly room, while the other engine, which is just beginning to work under its own fire, in turn now wears in a fresh engine, just out of the assembly room.

Reo Plant Completed—The new three-story, 252 feet by 252 feet, shipping and assembling plant of the Reo Motor Car Company, Lansing, Mich., was completed on December 2. This increases the floor space 190,512 square feet and provides shipping and assembly accommodation for 1,600 automobiles. Its floors are cement. It is equipped throughout with the latest improved automatic sprinkling system. An overhead runway connects it with the main factory buildings, thus providing a convenient easement to and fro for all traffic. Its covered shipping platform cares for twenty 40-foot box cars at one time, giving a loading capacity of 120 cars per day. The incoming freight is cared for on a separate track, which runs direct to the main factory buildings. From present indications the 1913 Reo output will far exceed 30,000 cars.

New factory addition of the Timken Roller Bearing Company, Detroit, Mich., to be used for the grinding of cups, cones and roller

Dinner of the Importers' Automobile Alliance held in the grand ballroom of the Hotel Astor, New York City, to celebrate the opening of the Thirteenth Annual Importers' Salon

IMPORTERS' Alliance Dines—The Importers' Automobile Alliance celebrated the opening of the Thirteenth Annual Salon in the grand ballroom of the Hotel Astor, New York City, last Thursday evening. The table was spread in the midst of the cars on exhibition and was decorated with the Vanderbilt Cup and the Elgin Trophy. Besides the importers and other automobile men, the automobile editors of the Metropolitan dailies and the editors of the national motor journals were present.

Paris with Reo—R. E. Paris has joined the Reo Truck Company, Lansing, Mich.

York Has 540 Automobiles—According to a recent count made by the York, Pa., police department there are 540 persons in that city owning automobiles.

Atlanta Buick Branch Moving—The Southern branch of the Buick Motor Company, Flint, Mich., is moving into its new Peachtree street building, Atlanta, Ga.

Scharlach Sternberg Manager—H. L. Scharlach has been appointed manager of sales for the Sternberg Manufacturing Company, makers of commercial vehicles, Milwaukee, Wis.

West Chester's Fire Engines—The Borough Council of West Chester, Pa., has decided to purchase three motor-driven chemical engines, one for each of the fire companies there.

Universal Adds Worm-Drive—F. K. Parke, general manager of the Universal Company, recently announced the addition of a one-ton worm-drive truck to the company's 1913 line.

Wilmington Banquet Date Changed—The Delaware Automobile Association has changed the date of its annual banquet from January 23 to 27. It will be held at the new Hotel Dupont.

Motz Factory Branch Opened—A factory branch house of the Motz Tire & Rubber Company, of Akron, O., was opened in St. Louis, Mo., recently. It is located at 4378 Olive street. E. G. Deibel is in charge.

New Automobile Bus Line—An automobile line from Lancaster, Ky., to Lexington will be started within the next fortnight. The promoter is the same company which has been running a line from the Madison capital to Lexington.

Studebaker Discontinues Louisville Branch—The Studebaker Corporation, Detroit, Mich., has discontinued its Louisville, Ky., branch. No wholesale business will be transacted hereafter and the retail end of the Studebaker concern will be handled by the Rommel Motor Car Company.

Mills on World Trip—D. B. Mills, president of the Rajah Auto-Supply Company, Bloomfield, N. J., and Mrs. Mills, are in California. On February 6, they will leave San Francisco for a trip around the world, returning home about June 1.

Doering Sales Manager Gramm—H. H. Doering has become a member of the executive staff of the John N. Willys industries, as sales manager of the Gramm Motor Truck Company, Lima, O. He will make his headquarters at the plant.

Galvin Resigns—H. J. Galvin has resigned from the Remy Electric Company, Anderson, Ind., to become president and general manager of the Galvin Specialty Company, also of that city. This company will manufacture and market gasoline machines for heating garment-pressing and laundry machinery.

Louisville Show March 12—At a recent meeting of the Louisville, Ky., Automobile Dealers' Association it was decided to hold the sixth annual exhibition of the organization March 12 to 15. The show will be held in the First Regiment Armory. Mr. P. S. Longest, secretary of the association, will handle all applications for space.

Important to Garage Owners—Garage owners in Cincinnati, O., will be vitally interested in the recent decision by high courts that where a machine is left in their care, and proper watch is not bestowed thereon, to the result that such car may be stolen or damaged, the proprietor of the garage is himself financially liable.

Pennsylvania Issues 59,365 Licenses—During 1912 the automobile division of the Pennsylvania State Highway Department issued 59,365 licenses, the highest number known since the establishment of the bureau. The licenses represent an income of $598,000. In 1911, 44,272 cars were licensed. The 24,000 mark in 1913 licenses was reached recently.

Wilmington Helps Visiting Automobilists—For the benefit of visiting automobilists who are passing through Wilmington, Del., the street and sewer department, which has control of the streets, has erected large signs on lamp posts in different sections of that city giving directions to the next towns and showing the streets and roads to follow. The signs, which are of sheet iron, are painted black, with silver lettering, making the words and finger marks very clear.

New Agencies Established During the Week

PLEASURE CARS.

Place.	Car.	Agent.
Boston, Mass.	Brown	F. E. Wentworth.
Bayfield, Wis.	Studebaker	William Bassett.
Canton, O.	Moon	Auto Service Co.
Cleveland, O.	Rambler	W. H. Barger Co.
Columbus, O.	Winton	Winton Sales & Repair Company.
Correctionville, Iowa	Cole	A. M. Rogers.
Dows, Iowa	Cole	C. W. Broeffle.
Hanford, Cal.	Paige Detroit	H. R. Cousins.
Harrisburg, Ill.	Moon	Chas. V. Parker.
Humboldt, Tenn.	Cole	Lannon & Johnson.
Joplin, Mo.	Moon	Joplin Supply Co.
Los Angeles, Cal.	Speedwell	Dwight Holmes.
Louisville, Ky.	Cole	Geo. Dunham & C. L. Anderson.
Macon, Mo.	Moon	Macon Garage Co.
Manhattan, Kans.	Cole	Gordon Belt Auto Company.
Marcus, Iowa	Moon	Johnson, Petty and Johnson.
Melbourne, Australia	Tudhope	W. B. Veirs.
Milwaukee, Wis.	Flanders Six	Hughes-McDonald Motor Car Co.
Milwaukee, Wis.	Garford	Hughes-McDonald Motor Car Co.
Mitchell, S. Dak.	Moon	Central Auto Supply Co.
Nashville, Tenn.	Lozier	Union Motor Car Company.
New Orleans, La.	Lozier	Automobile Maintenance Company.
Oakland, Cal.	Paige Detroit	Osen & Hunter Auto Co.
Oakland, Cal.	R-C-H	C. C. Eichelberger.
Ozona, Tex.	Cole	Ozona Auto Company.
Pasadena, Cal.	Cole	Lieher-Coryall Motor Car Company.
Passaic, N. J.	Lozier	Nathaniel Finch.
Phillips, Wis.	Cutting	Hunt Auto Sales Co.
Phillips, Wis.	Chevrolet	Hunt Auto Sales Co.
Phillips, Wis.	Ford	Hunt Auto Sales Co.
Phillips, Wis.	Herreshoff	Hunt Auto Sales Co.
Phillips, Wis.	Little	Hunt Auto Sales Co.
Phillips, Wis.	National	Hunt Auto Sales Co.
Quincy, Ill.	Cole	Machinery & Motor Company.
Sacramento, Cal.	Paige Detroit	Skinner & Elliott.
San Angelo, Tex.	Cole	Wm. R. Ede Company.
San Francisco, Cal.	Paige Detroit	A. E. Hunter Auto Co.
San Jose, Cal.	Flanders Six	William J. Benson.
Sherman, Tex.	Cole	Roberts Electric Company.
Stockton, Cal.	Paige Detroit	J. C. Skinner.
Texarkana, Tex.-Ark.	Moon	Paul Jones.
Union Hill, N. J.	Lozier	Union Automobile Company.
Vancouver, B. C.	Detroiter	H. W. Chambers.
Washington, Mo.	Moon	C. A. Krumsick.
Webster City, Ia.	Lozier	Hansen & Tyler Automobile Co.
Winnipeg, Ont.	Cutting	The Palace Garage.

COMMERCIAL VEHICLES.

Place.	Car.	Agent.
Los Angeles, Cal.	Speedwell	Dwight Holmes.
Milwaukee, Wis.	Garford Truck	Hughes-McDonald Motor Car Co.
Montreal, Can.	Mack	Canadian Fairbanks Morse Co.

ELECTRIC VEHICLES.

Place.	Car.	Agent.
Milwaukee, Wis.	Ohio Elec.	Hughes-McDonald Motor Car Co.

Vancouver Receives Glide—South Vancouver, B. C., recently received a 45-horsepower Glide, to be used as a combination police patrol and ambulance.

Schwartz Joins New Company—S. A. Schwartz has joined forces with Edward McKelvey and H. Walling, in organizing the S. A. Schwartz Oil Company with headquarters in Columbus, O.

Ziegler Goodyear Manager—H. P. Ziegler was promoted on January 1 to the position of general manager of the Chicago, Ill., district of the Goodyear Tire & Rubber Company, Akron, O.

Burnside in Insurance Field—F. H. Burnside, of San Francisco, Cal., has been appointed special agent and adjuster for the Firemen's Fund Insurance Company in the Pacific northwest.

Newark Concern Changes Hands—The C. W. Thompson Manufacturing Company, of Newark, O., has been taken over by W. A. Tungs and will be rehabilitated and extended. The concern produces a patent automobile tire clamp.

Tampa's Flying Automobile Squadron—Tampa, Fla., recently purchased a 6-cylinder Hudson, which is being used by W. M. Mathews, chief of the fire department. The car is equipped with chemical extinguishers and other apparatus for fighting fires.

Aldrich Resigns—Owing to a nervous breakdown, G. B. Aldrich, who has been general manager of the Dayton Automobile Truck Company, Dayton, O., has tendered his resignation to become effective at once. He still retains his holdings in that company.

Martin Tractor in Ottowa—Representatives of the Martin Tractor Company, Indianapolis, Ind., were in Ottawa, Can., recently with a view of making their Canadian headquarters in that city. This company manufactures motor tractors for pulling fire engines and other vehicles.

Eagal Resigns—J. H. Eagal has resigned his position as district manager of the Oldsmobile Company, Tacoma, Wash., and has accepted a position with the Consolidated Motor Car Company of San Francisco, Cal. Mr. Eagal will have charge of the commercial department.

Hughes and McDonald Join—O. R. Hughes, Marshfield, Wis., and John McDonald, Jr., Milwaukee, Wis., have joined forces and organized the Hughes-McDonald Motor Car Company, Milwaukee, Wis., to represent the following lines: Garford, Flanders Six, Ohio electric and Garford truck.

Colorado's New Road—Preliminary surveys for the new automobile road from Colorado Springs to Cripple Creek, Colo., have been completed and work will start next spring. The road is to be built along the Colorado Springs stage line through Cheyenne Canon. The government has appropriated $2,000.

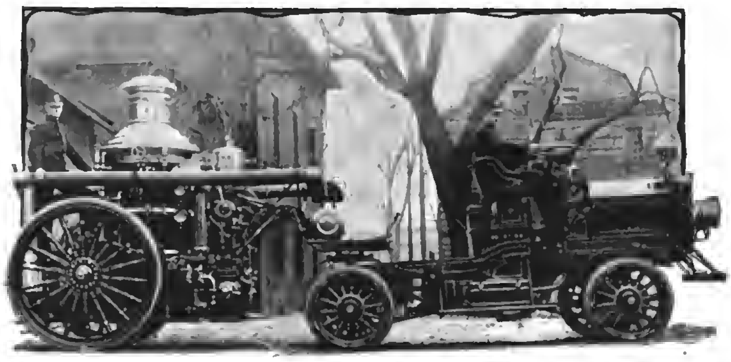
Toronto's Show February 20—The Toronto, Ont., Automobile Trade Association's show will be held from February 20 to March 1, 1913. Three buildings—the new Dominion Government, the Transportation and the Horticultural—will probably be utilized, and their combined floor area will provide all the space that is likely to be required.

Victoria Show Postponed—Owing to its inability to secure suitable quarters close in or to get the only ones at all available, except in the rainy season, the Victoria Automobile Dealers' Association recently postponed the automobile show at Victoria, B. C., until autumn, when it will join forces with the agricultural exhibition in a building of its own.

Road Building Delayed—Nearly 100 road petitions asking for in the neighborhood of 300 miles of water-bound pike in Ohio have been found invalid by the Circuit Court through a recent decision of the State Supreme Court declaring the Garret road law invalid. This decision will mean that the building of new roads in the country will be delayed for some time.

Change in Tacoma's Course—Plans are now on foot to make a decided change in the Tacoma, Wash., automobile race course which will mean the shortening of the track from its present length to approximately 5 miles to 3 miles to 3 1-2 miles. There are two dangerous curves near Lakeview and it is planned to cut off the road altogether through the town of Lakeview.

Regal in France—R. M. Lockwood, representative of the Regal Motor Car Company, Detroit, Mich., in France, has completed a deal in Paris which will place the sale of his product and all other American made cars in all the provinces of France. He has established a garage which is a formidable appearing structure with a capacity for 400 automobiles. Its management is backed with a capital of 1,250,000 francs.

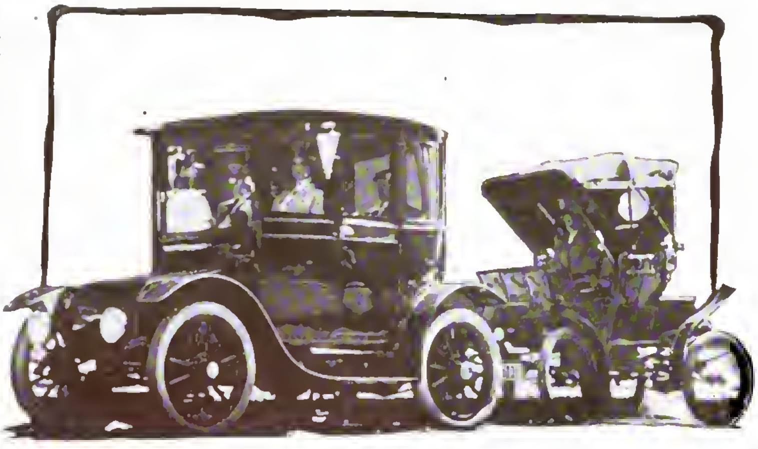


Gasoline-electric tractor and steam fire engine combination recently installed in the service of the Hartford, Conn., fire department. The gas engine used is of the T-head type with 5.5-inch bore and 6-inch stroke and is direct coupled to a 125-volt generator. Drive is from four motors, one for each wheel, of 88 volts. The current is controlled through a street car type of controller

Steinhauer General Manager—F. P. Steinhauer has been employed by the Colby Motor Company, Mason City, Ia., as general sales manager.

Seibel to Manage Motz—A branch factory of the Motz Tire & Rubber Company, Akron, O., has been established in St. Louis, Mo., with E. G. Seibel as manager.

Stone with Landman-Griffith—M. Stone, formerly with the Gamble Motor Car Company, Toledo, O., has accepted a position with the Landman-Griffith Company, of that city.



Another meeting of the new and the old, bringing forth strikingly the advance in electric car construction during the past decade. The car in the foreground is a 1913 Baker brougham, while that in the background is a Baker stanhope built 12 years ago

Portland Club Increasing Membership—The Portland, Ore., Automobile Club is making strenuous efforts to increase its membership to 1,000 before 1913. The membership fee is now but $10 but will be raised to $25 on that date.

Carnahan Resigns from Swinehart—F. G. Carnahan will sever his connection on January 15, 1913, from the Swinehart Tire & Rubber Company, Cleveland, O., to assume a position with F. G. Carnahan & Company, Akron, O., dealers in rubber stock.

South Bend Forbids Speed—The board of public safety of South Bend, Ind., has adopted resolutions forbidding the drivers of automobiles of the police and fire departments from driving their machines at a rate of speed greater than 30 miles an hour.

McGiehan Resigns—T. H. McGiehan has resigned his position of manager of the New Orleans, La., branch of the Goodyear Tire and Rubber Company, Akron, O., to accept the position of general manager of the Motz Tire and Rubber Company, Akron, O.

Eagal Resigns—J. H. Eagal has resigned his position as district manager of the Oldsmobile Company, Tacoma, Wash., and has accepted a position with the Consolidated Motor Car Company of San Francisco, Cal. Mr. Eagal will have charge of the commercial department.

Frisco's Truck Club.—The San Francisco, Cal., Motor Truck Association is the name of an organization of motor truck men of that city recently organized. At the meeting there was considerable enthusiasm displayed, and it was the general belief that there was a very wide field for the activities of such an association. Its immediate formation was the result.

Pennsylvania Improves Roads—Since the Pennsylvania highway department took over 8,000 miles of highways in the state on June 1, the department has improved 4,700 miles of roads. This total includes those that have been rebuilt under the seventy-nine contracts so far let under the Sproul act and those that have been repaired by the road superintendents, forty-seven of which have been named out of fifty the law calls for.

Canada Has 21,290 Automobiles.—The popularity of the automobile in Canada, and incidentally the prosperity of the Canadian farmer, is shown in the latest statistics. According to the figures there are at present 21,920 automobiles in Canada, or about one car for every 323 inhabitants. The rate varies considerably in the different provinces, Nova Scotia having only one automobile per 851 people, while in Alberta there is a car to every 125 inhabitants. British Columbia ranks next as a motoring province.

Incorporations of Automobile Companies During the Week

AUTOMOBILES AND PARTS.

ALBANY, N. Y.—Electric Coach Corporation of New York City; capital, $500,000; to manufacture and engage in the motor vehicle business. Incorporators:

BOSTON, MASS.—Norwalk Motor Car Company; capital, $75,000. Incorporators: Charlea C. Smith, James W. Briggs, M. A. Beaudet.

BOSTON, MASS.—Lozier Motor Car Company; capital, $1,000. Incorporators: Ralph B. Nettleton, Stanley G. Barker, Robert S. Barlow.

CHICAGO, ILL.—A. W. Goeiner Auto Sales Company; capital, $25,000; to manufacture automobiles and accessories. Incorporators: A. W. Goeiner, Michael Feinberg, C. E. Becker.

CINCINNATI, O.—Hermes Motor Car Company; capital, $30,000: to manufacture automobiles, trucks and accessories. Incorporators: Albert Kloybolte, Powel Croslet, Jr., Charles Eissen, Slater H. Aiken, John C. Rogers.

DOVER, DEL.—Standard Motor Company; capital, $31,000,000; to manufscture, construct, maintain and operate automobiles, wagon trucks, motor cycles, flying machines. Incorporators: Donald Muhleman, Wm. J. Maloney, Herbert E. Latter.

JERSEY CITY, N. J.—The Wheel of Fortune Corporation; capitsl, $600,000; to conduct a general automobile business. Incorporators: L. H. Gunther, H. A. Black, J. R. Truner.

LOUISVILLE, KY.—Miller, White & Company; capital, $5,000; to deal in automobiles. Incorporators: R. W. Miller, A. W. White, William Atix.

MORGANTOWN, W. VA.—Chaplin-Dille Motor Car Co.; capital, $25,000; to manufacture and deal in automobiles, trucks, aeroplanes, etc. Incorporators: B. M. Chaplin, M. C. Wildman and Jas. E. Dille.

MORRISTOWN, N. J.—Morristown Automobile Company; capital, $25,000: to conduct a general automobile business. Incorporators: J. J. Lyons, L. Van Gansbeck, Alex. Newmark.

NEWARK, N. J.—Universal Motor Truck Company of New Jersey; capital, $50,000; to deal in motor trucks, etc. Incorporators: John Kramer, Grace Cleveland, Pasquale Mauan.

NEW YORK CITY, N. Y.—Drouet & Page Company; capital, $10,000; to manufacture motors of all kinds. Incorporators: Conrad Milliken, Ingrid E. Larsen, Martin B. Rofman.

NEW YORK CITY, N. Y.—Electro Coach Corporation; capital, $500,000; to manufacture automobiles. Incorporators: John Larkin, Alexander Andrews, Richard J. Lynch.

NAW YORK CITY, N. Y.—Standard Motor Company; capital, $31,000,000: to manufacture, construct, maintain, store, care for, sell and deal in and with automobiles, etc. Incorporators: Donald Muhleman, W. J. Maloney, Herbert E. Latter.

NEW YOAK CITY, N. Y.—E. J. Sullivan Corporation; capital, $5,000: to conduct an automobile business. Incorporators: Robert C. Ballantine, Eugene J. Sullivan, Walter F. Hopper.

PORT CLINTON, O.—Holmes Tractor Company; capital, $50,000; to manufacture farm tractors of all kinds. Incorporators: George H. Holmes, George W. Sloan, R. S. Galleher, A. R. Laschinger, F. S. Dennernberg.

ROCHASTEA, N. Y.—Ball-Washhurne Motor Company; capital, $25,000; to manufacture and sell motors. Incorporators: Ward H. Ball, Charles H. Washburne, Asa R. Ball.

WASHINGTON, D. C.—American Motor Traffic Company; to operate and manufacture motor vehicles for all uses. Incorporators: E. S. Alford, S. J. McFarren, W. J. Moore, A. L. Kley, J. C. Muncaster, J. C. Menoher.

GARAGES AND ACCESSORIES.

ALBANY, N. Y.—New York Motor Speedway Association; capital, $1,000,000; to hold aeroplane, auto and motor vehicle races, displays and contests. Incorporators: William B. Allen, Herbert J. Carter and Alfred B. Casner.

BUFFALO, N. Y.—United States Rubber Reclaiming Company; capital, $2,400,000; to manufacture and deal in rubber goods, tires, etc. Incorporators: Theodore W. Bassett, Rudolph A. Lowenthal, Cornelia Beebe.

JAMESTOWN, N. Y.—Eagle Garage Company, of Jamestown; capital, $25,000. Incorporators: Samuel B. Robbins, Olive M. Spencer, George Rappole.

NEW YORK CITY, N. Y.—New York Motor Speedway Association; capital, $1,000,000; to construct a motor speedway for racing. Incorporators: William B. Allen, Herbert J. Carter, Alfred B. Casner.

NEW YORK CITY, N. Y.—Stewart-Warner Speedometer Corporation; capital, $25,000; to manufacture speedometers. Incorporators: Elmer E. Holmes, J. K. Stewart, C. B. Smith.

PORTLAND, ME.—Portland Automobile Dealers' Association; capital, $10,000. Incorporators: Fred A. Nickerson, Albert M. Spear, Jr., Ernest E. Brewer, Luther C. Gilson.

SAN ANTONIO, TEX.—Motor Car Supply Company; capital, $5,000. Incorporators; C. P. Guthrie, H. B. Wyne, James Harrison and Will Harrison.

WEST SENECA, N. Y.—The George Schuster Garage & Sales Company; capital, $5,000; to conduct a general garage business. Incorporators: Jacob F. Berner, Sr., Reinhold C. Berner, George Schuster.

WILLIAMSON, N. Y.—Williamson Garage Company; capital, $20,000; to manufacture and repair automobiles. Incorporators: Robert Carr, Charles DeZutter and Alfred F. Raymer.

WINNIPEG, CAN.—Dominion Garage; capital, $250,000; to conduct a general garage business.

CHANGES OF NAME AND CAPITAL.

CARROLTON, O.—L. & M. Rubber Company; increase of capital from $120,000 to $500,000.

CLEVELAND, O.—Cleveland Auto Livery Company; increase of capital from $10,000 to $25,000.

HARTFORD, CONN.—Universal Auto Company; capital increased from $3,000 to $30,000.

SYRACUSE, N. Y.—H. H. Franklin Manufacturing Company; increase of capital from $300,000 to $1,500,000.

YOUNGSTOWN, O.—Auto Rubber & Cycle Company; change of name to Auto Rubber and Mill Supply Company.

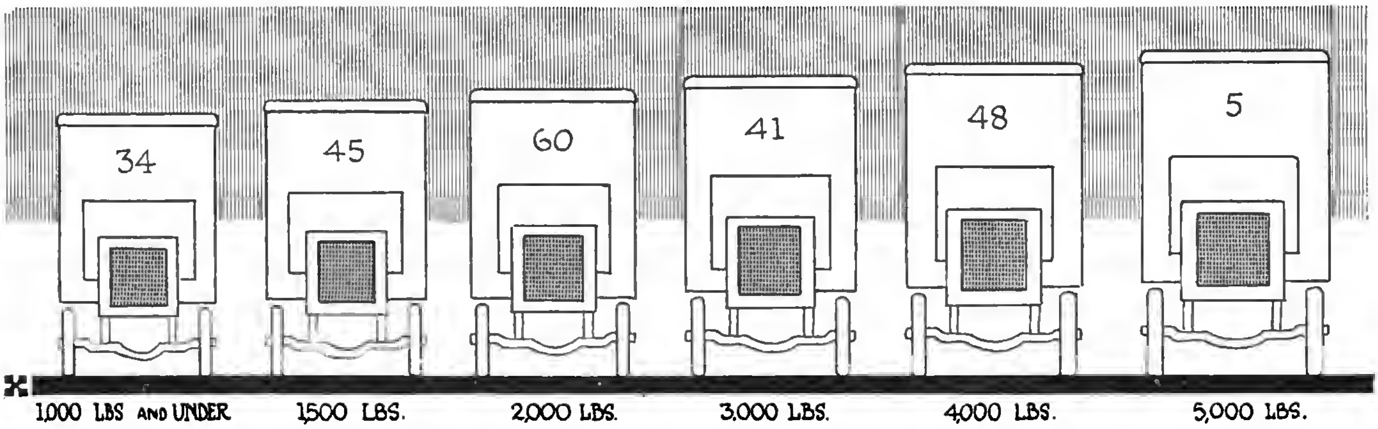
A Full Account of the Opening of New York's Thirteenth Annual Show Given on Pages 218 to 230

THE forthcoming annual New York truck show which will open its doors to the public on January 20 will be the most representative that has ever been held. The exhibits will be staged in Madison Square Garden and the Grand Central Palace laying bare to an expectant public the offerings for the ensuing season. There have been numerous refinements made in body construction during the last year, as well as improvements in the methods of expeditiously dumping heavy loads. According to present indications this is a year of refinements rather than changes.

Comparing the statistics that have been furnished by makers of gasoline commercial vehicles for the coming season with those of last year there is a decided tendency on the part of a good proportion to increase the number of models manufactured. In cases where a small model was manufactured last year one or more chassis of heavier carrying capacity have been added to the line, and in not a few cases the makers of heavy duty trucks having found that they were losing business with concerns to whom they had sold the large trucks when these customers came to buy trucks of smaller capacity which they did not make. A competitor by this means obtained the footing in some cases equally as strong as the pioneer manufacturer. Besides the question of additional models the subject of overload has been met by many of the manufacturers in the following manner: Without directly stating or guaranteeing that their trucks will withstand any specific overload over and above the rated capacity they nevertheless appreciate the fact that at times the trucks may be inadvertently overloaded or undue strain may be caused by circumstances beyond the control of the owner or his driver. Consequently, the chassis frames, axles and steering gears, have in many cases been strengthened to take care of additional strain.

It is somewhat confusing to consider trucks as built according to yearly models; as far as the truck business is concerned this never was the case; improvements may have been added during the preceding year that have not been announced prior to the show time, and, again, certain types of models have been purposely withheld until the event of the show in order to present



Showing the numbers of truck models of different capacities up to 5,000 pounds

them to the buying public when its mind is in a receptive mood. The date of manufacture of the truck and its designating model title are the only points that manufacturers consider. Such things as modes and fancies do not enter the commercial field and so cause to be discarded what otherwise might be good.

The much-debated question of motor under the bonnet or motor under the seat has not materially changed in aspect during the last 12 months. Between thirty and forty vehicles have remained unchanged except perhaps insofar as relates to minor details.

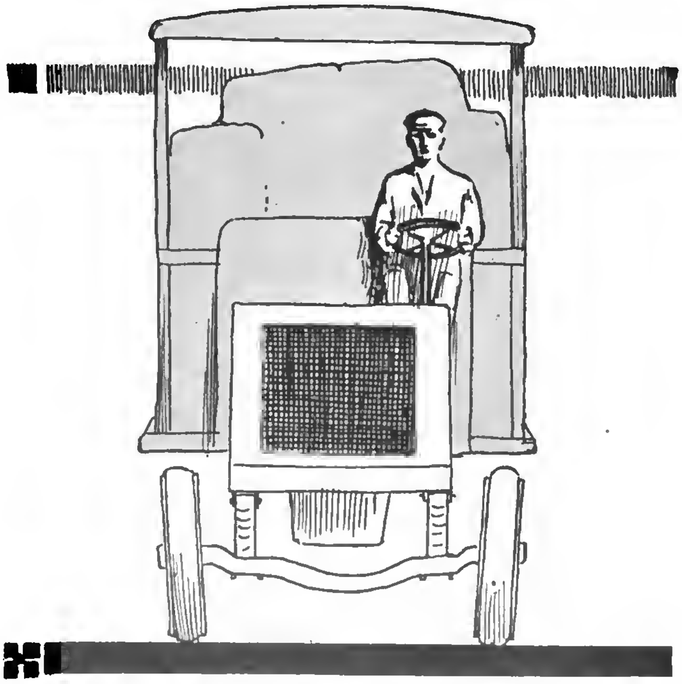
One hundred and sixty-four commercial vehicle makers of gasoline trucks responded to calls for specifications, and out of this number there was a total muster of 409 chassis models. This shows a growth of eighteen new makers listed as compared with 1912 and an addition of eighty-eight chassis models. When it is taken into consideration that such concerns as the Franklin, Mitchell, Cartercar, Case, Lozier, Interstate, Premier, Hudson and Ohio, as well as a few others, have discontinued the manufacture of commercial vehicles, the list of new makers must be correspondingly increased in order to make up the sum total given above. Some of the concerns who have entered the commercial vehicle field during the last year are: Stewart Corporation, Stewart Iron Works, National Motor Truck Company, Nordyke & Marmon, Motor Car Manufacturing Company, Standard Motor Truck Company, Gramm-Bernstein Motor Truck Company, Krebs Commercial Car Company, KaDix Newark Motor Truck Company, White Star Motor & Engineering Company, Driggs Seabury Ordinance Corporation.

The general characteristic features of truck design have undergone very little change during the last year. There has been a general cleaning up on the part of the majority of manufacturers and it is safe to say that the year that has passed besides being a good one for the truck business in general has been extremely educational as several of the trucks that are in operation have passed from the stage of new toys to everyday necessities and have shown themselves in their true light. If the result was a good one the manufacturers have themselves to congratulate upon their success, but if real dissatisfaction or even indifferent results were met with in certain quarters, lessons learned will act as a guide to prevent the recurrence of such mistakes.

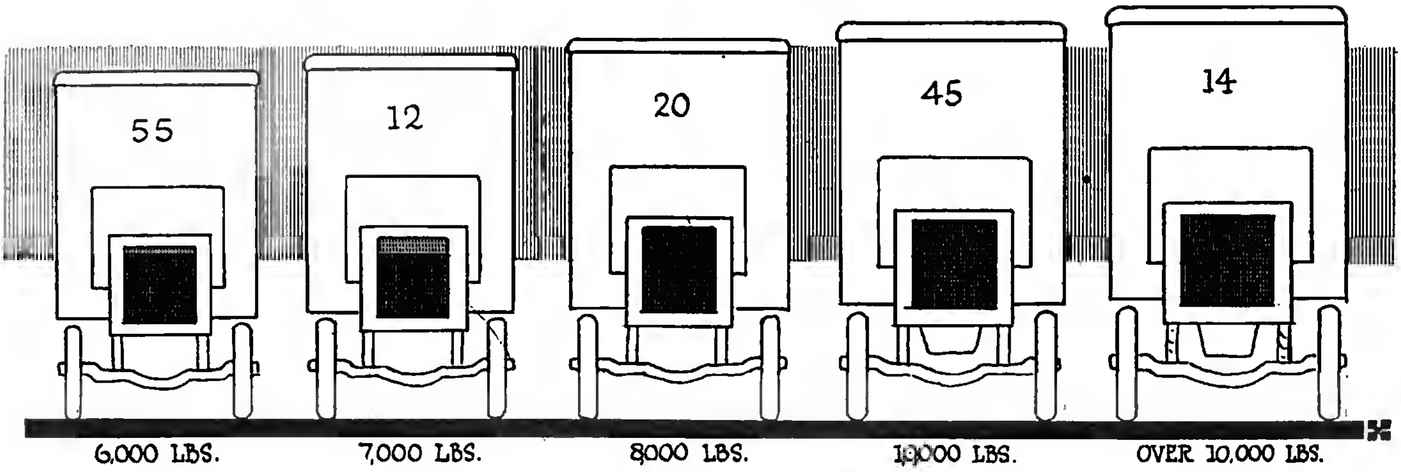
Reference has already been made to the position of the motor and the same remarks apply to the general mechanical features of the motor as well. Very little has been done along the lines of changes and in another part of this issue of The Automobile a series of curves is given, showing the S. A. E. horsepower, the bore and stroke, as well as the piston displacement for the various makes. In order to arrive at a common basis of comparison, the useful load capacity in pounds has been divided by the piston displacement in cubic inches, thereby giving the ratio of useful load in pounds per cubic inch of piston displacement. It would be impossible to attempt to closely analyze the figures that this calculation affords, as the question of the efficiency of the engine is entirely disregarded as well as the engine speed and a number of other considerations which are not to be neglected.

The clutch has received very little alteration at the hands of designers of trucks; in figures compiled of percentages of this and last year's models there is a slight tendency towards an increase of favor of the leather-faced cone-type clutch in preference to the disk or band types. Provided the area of the contacting surfaces is sufficient and the degree of the angle of the male member suitable there is no reason why the cone type of clutch will not give most excellent results. Its co-efficient of friction is in many cases increased by the addition of cork inserts. Its great feature is its simplicity.

Gear-box location seems to be a point upon which the different makers have various opinions as is indicated by the number of concerns building the various types. Out of the total number who have responded 222 chassis are fitted with the transmission gearset amidships, the power being delivered from the clutch to the gear-box and thence to the differential, usually by universal-jointed shafts, leaving the transmission an entirely independent unit. In seventy-eight chassis the transmission is attached to the rear end of the crankcase housing, thereby forming a unit of the motor and transmission. In seventy-five chassis the transmission and differential form a unit with the jackshaft housings in the case where chain drive is employed. The number of trucks using rear axle and transmission unit combination is extremely small.



Out of a total of 375 truck models there are 118 with the steering on the left

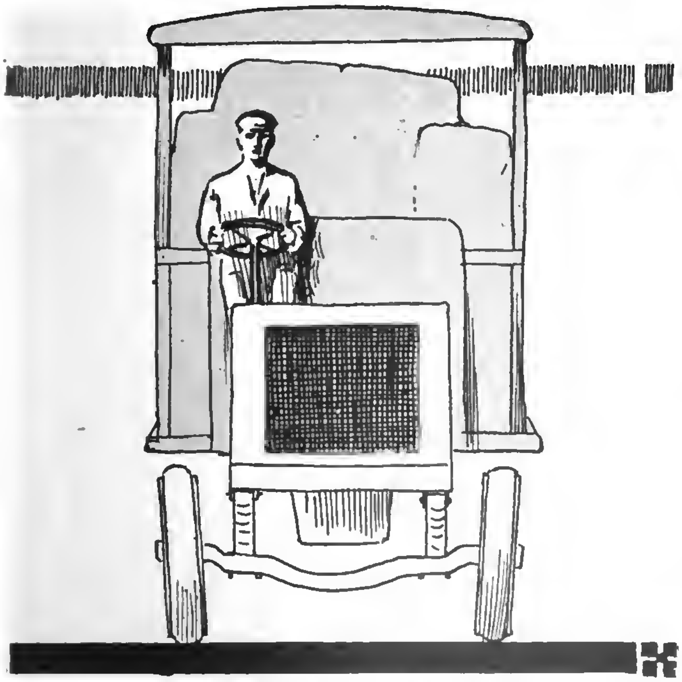


Showing the number of truck models of different capacities from 6,000 pounds upwards

One of the principal features of truck design that has been carefully watched by both manufacturer and purchaser has been the question of worm drive. Credit must be given to the pioneer of this class of drive in this country, namely the Pierce-Arrow, and this coming season will see more converts among whom may be mentioned the Smith, Diamond T, Universal, Blair, Schacht and Wolverine. The Smith trucks, of 3.5 and 6-ton capacities, both use worm drive, the Schacht has worm drive fitted to its 1-ton model, the Blair is being built in three models, of 1.5, 2.5 and 3.5-ton capacity with worm drive as well as the Universal Motor Truck in its recently announced 1-ton model. The Wolverine Detroit, a 1,000-pound wagon, is also fitting worm drive to this season's models.

The question of the suitability of steel wheels has not been much debated in America and it is somewhat surprising that this type of construction has not gained more headway. Three prominent concerns, namely the White, Smith and Locomobile, are using steel wheels as a standard in all their models for the coming season.

The chain still claims the premier position as the means of final drive in all carrying capacity models. Out of the total number 317 chassis are fitted with chain, fifty-three with bevel drive, seven with worm drive and ten models with internal or external gear drive. A new type that is making its appearance this year may be mentioned, namely, the Walters, built along



Out of a total of 375 truck models there are 257 with the steering on the right

the lines of the French Avant-train Latil, which opens up a means of utilizing existing horse wagons, thereby saving considerable loss when these have to be sold for what they will fetch to make room for conventional gasoline or electric truck.

There is a preponderating majority in favor of roller bearings for use in the rear wheels, there being 245 chassis fitted with roller bearings as compared with ninety-eight chassis fitted with ball bearings. Ball and roller bearings are fitted to twenty-five chassis and four chassis are fitted with plain bearings. These latter are in most cases of small carrying capacity. While it is possible to make heavy trucks with plain wheel bearings, the problem of lubrication and the damage that may be caused by want of lubrication have seriously retarded any decided efforts in this direction. Ball bearings of the annular type alone without any provision for end thrust do not give satisfaction after a certain load has been reached, despite the fact that the balls are large enough and proportionate to the load. The adaptability of the roller bearing to carry the load and take end thrust makes it particularly adaptable for truck work as is indicated by the number of manufacturers using it.

Dealing closer with details of design, the method of cooling claims the premier position. There are 270 models using a pump to circulate the water, which shows a 5 per cent. increase over last year's figures, eighty-four models using the thermo-syphon system, and thirty models who rely solely upon air. The majority of these latter have two-cycle motors.

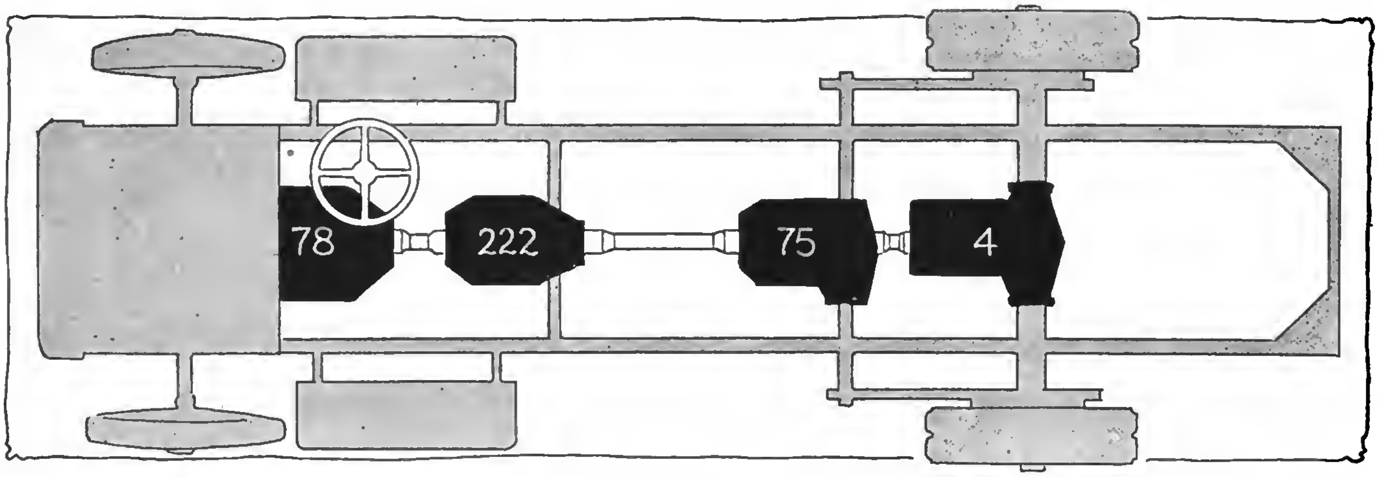
Approximately five-eighths of the total number of chassis listed employ dual ignition, there being 246 of this type. The remaining three-eighths are divided into 110 models, using single ignition and fifty-one models employing two independent sets of ignition classified under the heading of double ignition.

Governors are being fitted to an increasing number of chassis. The point at which these are set to operate being largely dependent upon the carrying capacity of the vehicle.

The 3,000-pound wagon has its speed restricted when a governor is fitted, in many cases to 15 miles per hour. The 6,000-pound wagon has its speed regulated to 12 miles per hour, and the 5-ton truck between 8 and 10 miles per hour. There is no doubt that there is an increasing tendency toward the fitting of some means of controlling the speed of trucks, the unanimous opinion being that a governor will satisfactorily control the maximum speed while traveling along the level of high gear. When it is necessary, however, to increase the engine speed on the lower gears in order to extricate a truck from bad ground or heavy sand, the restriction with the governor sometimes acts in a detrimental manner.

While the left-hand drive type of vehicle is gaining favor there is still a considerable number of right-hand driven vehicles in excess of the first mentioned type. Out of 375 chassis there are 257 which have the steering wheel placed on the right hand side of the vehicle, and 118 with the steering wheel on the left.

As an indication of the enormous growth of the truck busi-



Showing the trend of gearbox location in the various models of trucks for the coming season, showing the numbers with various locations

ness the plans for next year in most cases show that the number of vehicles manufactured will be two or three times that of 1912. It is a well-known fact that the sales of 1912 were at least 100 per cent. more than 1911.

Among the changes and additions that have been made recently may be mentioned the following:

ADAMS—In addition to the 1 and 1.5 models a 2-ton vehicle known as model E has been added, following the general lines of last year's models. The new models will be equipped with a 30-horsepower motor and a change has been made to a multiple-disk clutch. The wheelbase of the new model is 140 inches and springs 50 inches in length will be used at the rear.

ALCO—No new models will be brought out by the American Locomotive Company during 1913. Most of the improvements in the 1913 models were incorporated in the 1912, including a new steel quick-acting service brake lined with a high-friction lining in place of the locomotive type brake; the driving sprockets have been made removable. A specially designed drive plate clutch and a new carbureter with an adjustment on the dash have been incorporated as well as an alteration to the driver's cab, square section spokes for the rear wheels and a strengthening of the bumper.

ATTERBURY—The Atterbury Motor Car Company has increased the number of models, having added a 1,500-pound wagon with internal gear drive, and a 1.5-ton truck to its existing line of 1, 2, 3 and 5-ton trucks.

AVERY—A 1 and a 5-ton truck have been added to the previous models manufactured. The entire line being fitted with governors. One of the features of the 5-ton truck is that the seat and foot boards over the motor can be tipped forward, thus offering easy accessibility. The disk clutch has been modified, twelve pins being used instead of six as heretofore.

BESSEMER—In addition to the 2,000-pound capacity chassis manufactured last year, 2 new models have been added, namely 1.000 and 3,000-pound capacities. Some minor changes have been made.

CHASE—The most recent addition to this line is the 500-pound wagon. The difference between this model and the 1,000, 2,000, 3,000 and 4,000-pound chassis is that it is left-hand driven instead of right hand, as is the case in the larger models.

DART—Two entirely new models are being placed on the market this year, one of 1,500-pound capacity and the other of 2,000 to 3,000-pound capacity. These trucks will both be four-cylinder left-hand drive and center control. The former will have a cone clutch and the later multiple disk clutch.

FEDERAL—No changes have been made in the design of the Federal 1.5-ton truck. One of the features of this car is that it is fitted with a governor restricting the speed to 15 miles per hour.

GARFORD—In the near future a new 2-ton truck will be added to the existing line ef vehicles which consist of 1.5, 3 and 5-ton trucks manufactured at present. The 1913 line includes 2, 3, 4, 5 and 6-ton trucks, but the details of the 2-tonner are not yet available.

GRAMM—Three new models of the motor-between-the-seats type of 1, 2 and 3.5-ton capacities are being placed on the market for 1913. A feature of these trucks will be the Gray & Davis electric starter. The motor is attached to a subframe which is mounted on four coil springs, a governor being provided to restrict the engine speed to 1,000 R. P. M. The four-speed gearset is composed of individual dog clutches, the gears remaining in constant mesh. The specifications of the 1-ton truck differ from the other two in several points. A selective gearset is employed on the 1-ton truck, and the governor cuts out at 1,200 R. P. M.

B. A. GRAMM'S—These trucks are built in two sizes, namely of 2 and 3.5-ton carrying capacities. Both models are fitted with the same size motor, multiple-disk clutch, individual clutch type transmission, final chain drive.

GENERAL MOTORS—1,500-pound, 1.5 and 2-ton trucks have been added to the existing line for the coming season. Regarding mechanical improvements, the high speed is now direct instead of indirect, and a change has been made from multiple-disk clutch to cone clutch.

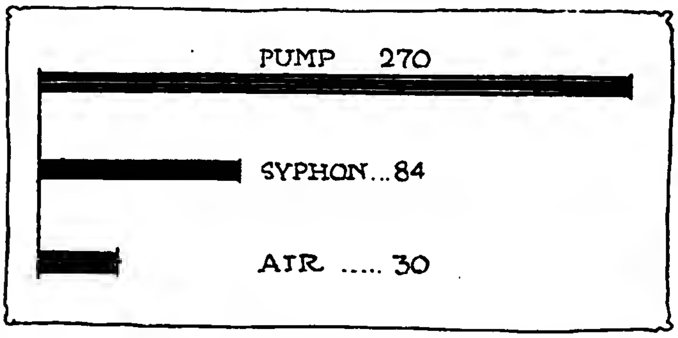
IDEAL—Manufactured by the Ideal Commercial Company, of Akron, O., the 1,500-pound capacity truck will be under the name of Akron. New mechanical features and improvements are mostly in the transmission. The clutch is automatically thrown out when the gears are shifted from one speed to another. This forms a foolproof mechanism.

INTERNATIONAL—The Mack, Hewett and Saurer trucks remain practically unchanged, except for some minor details. In addition to the other Mack models, a new 1,500-pound chain-drive model will be added. The specifications for this machine, however, are not yet available.

KADIX—This is a new make of truck and is being manufactured in four sizes. Namely, 2, 3, 5 and 6-ton capacities. The first two models have the motor under the bonnet and the second two have the motor under the seat. Spring suspension is employed in connection with the motor subframe and a straight-line driveshaft is used. There are several novel features in this truck, including the jackshaft housing, radiator suspension and brake mechanism.

KELLY-SPRINGFIELD—These trucks have changed air-cooled motors under the seat to water-cooled motors placed under a sloping bonnet. Two models at present manufactured are of 1 and 3-ton capacities, respectively. The steering is placed on the left and the control in the center. The motors are governed to 1,200 R. P. M. in the case of the 1-ton and 900 R. P. M. in 3-ton trucks.

KNICKERBOCKER—A 1-ton truck with a four-cylinder motor placed forward under a hood, selective gearset, and final chain drive has been added to last year's line which consisted of two models of 3 and 5-ton capacities, which will be continued this year practically unchanged.



Showing how the truck motors are cooled, comparing water-pump, water-centrifugal and air types

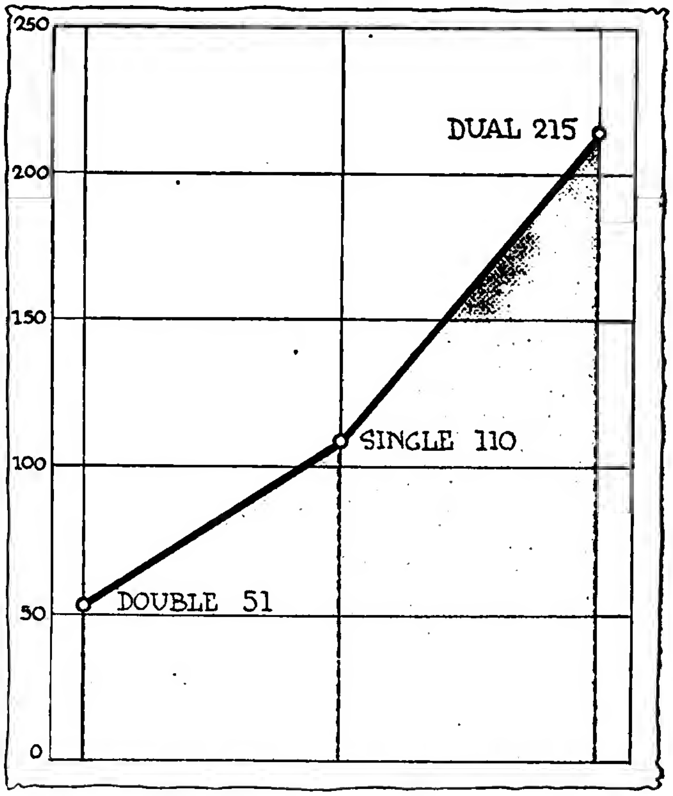


Chart showing the numbers of trucks using single, dual and double ignition respectively

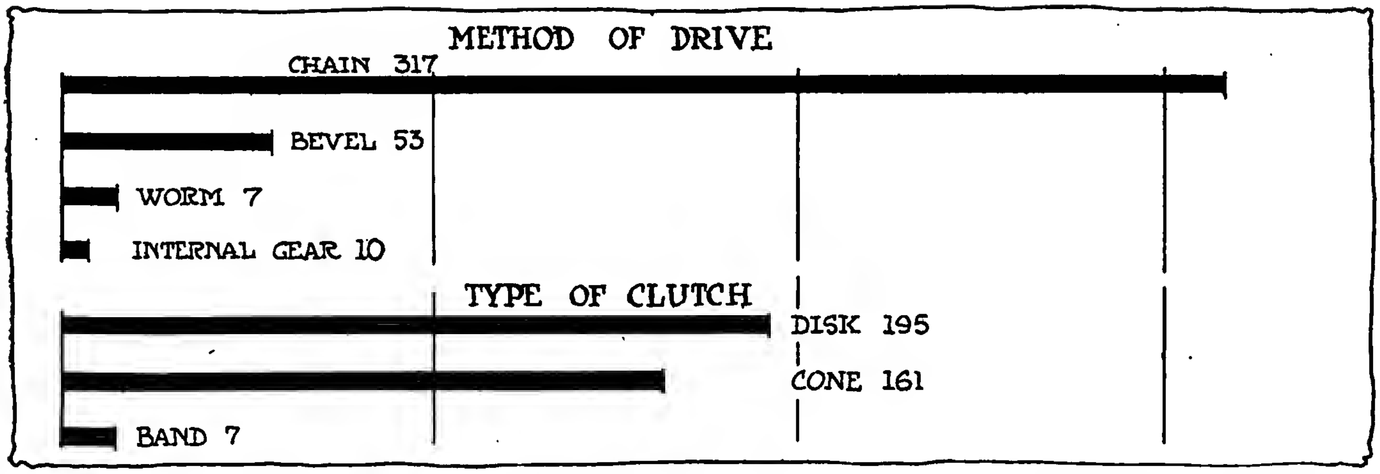

Upper—Comparing the numbers of cars and the methods of drive. Lower—Comparison of the different types of clutches

KNOX—In addition to the Knox Martin tractor, only two models of conventional trucks will he manufactured next year. These being of 2 and 3-ton sizes. The chief mechanical changes over last year's vehicles consist of stronger steering gears and front axles, springs with flatter arch and sundry minor details.

LAUTH-JUERGENS—The latest addition to this line is the 5-ton truck. In order to take care of frame wearing self-aligning hearings are used in the jackshift housing. Coil springs have been incorporated, acting as shock-absorbers and relieving the main springs under full load. The hubs of the wheels are so constructed that a choice of four or five different bearings may he had, such as double row annular, parallel roller, taper roller aod ordinary angular.

LIPPARD-STEWART—Quite a few changes have been made in the 1913 Lippard-Stewart, among which are the following: A 30-horsepower motor takes the place of a 22-horsepower motor hitherto fitted, a leather face cone clutch is used instead of a multiple disk. This is a separate unit, oot being incorporated with the transmission. A new transmission has been fitted and the length of the rear springs has been increased hy 5 ioches. Full elliptic springs have given way to semi-elliptic springs, and, besides the length of the frame heing made greater, the size of section has been increased. Steering gear, tires and gasoline tank have all heen increased in size.

LOCOMOBILE—The 5-ton Locomobile which was placed on the market last year will he continued without any alterations.

McINTYRE—The design and construction of commercial vehicles of this make have been entirely changed. The line comprises a 1,000-pound chassis with a two-cylinder motor and 1,000, 1,500, 3,000, 6,000 and 10,000 capacity vehicles. Governors are fitted to all models and the design of motor, clutch and gearset of the 3,000 and 6,000 pound chassis is the same.

MAIS.—The principal change to be noted in the construction of these chassis is that all models now use pressed steel frames. Other changes are unimportant, heing of a minor nature.

PACKARD—The latest addition to this line is the 5-ton model, which made its appearance during last season, shipments of which commenced about December 1. The only mechaoical change from last year is in the ignition apparatus. An automatic magneto is now fitted.

PEERLESS—The 1913 trucks will not he different in any way from the 1912 product. These trucks are made in 3, 4, 5 and 6-ton capacities.

PIERCE-ARROW—The 5-ton model Pierce-Arrow continues to he the only model marketed by this concern. It is fitted with worm drive. The general design has not been changed.

PIGGINS—The Piggins is made in 3 capacities of 1, 2 and 3 tons. With the exception of a change of motor, the 1913 models are the same as 1912.

PLYMOUTH—Two new models of 2 and 3-ton carrying capacities, both equipped with a six-cylinder engine, are heing placed on the market this year. The power is transmitted through friction drive.

REO—A four-cylinder model of 1.5 to 2-ton capacity has been placed on the market in addition to the single cylinder 1,500-pound truck. The motor is placed forward under a hood, aod the final drive is hy chain.

SERVICE—Two heavier models have been added to this line of trucks. Previously, carrying capacities were only 1,500 pounds and 2,000 pounds. The new models have carrying capacities of 3,000 pounds and 6,000 pounds, respectively. The mechanical improvements in the trucks include double spring suspended radiator, heavier axle construction and Grant roller bearings in transmission and rear axles, as well as S. K. F. self-aligning bearings in the jackshafts.

SMITH—There will he no mechanical changes over 1912. The principal features will he retained, including worm gear drive, herringbone gear transmission, cast steel wheels with hollow spokes, old mechanical parts pack of the motor and clutch, inclosed in dustproof cases and run in an oil bath. A three-plate dry disk clutch will he used, constituting the only mechanical change, except that the motor of the 3.5-ton vehicle is larger.

STEGEMAN—A new 1,500-pound delivery wagon will make its appearance this year, in which hevel gear drive takes the place of inclosed chains used on the large models.

SCHACHT—The 1912 models are heing continued in practically the same form for 1913 aod in addition to these there will he added a new 1-ton worm drive truck, also a 1.5 to 2-ton worm drive truck.

SPEEDWELL—To the line of 4 and 6-ton trucks, a 2-ton vehicle has been recently added, the same general design being carried out. Mechanical changes include a diagonal cross-member at the rear of the chassis frame and a new style jackshaft hanger which carries the forward extremity of the radius rods. Now the motor and transmission are hung from a subframe cushioned at the two forward points between double coil springs and is pivoted at two points in the rear. The front end of the frame is protected by a wood humper and the starting-crank is made to fold. A new centrifugal governor has been added to all models.

UNIVERSAL—Announcement has been made of a new 1-ton model in which a Wallwork worm drive is incorporated. The motor in this chassis is placed under a hood in contrast to the larger types in which the motor is placed under the seat. A power hoist driven hy a chain from an extension of the sprocket shaft is a useful innovation.

VELIE—A new 1-ton model has heen added to this line and, instead of chain as is used on the larger models, shaft drive is employed. A governor is fitted on the 2 and 3-ton models, restricting the speed to 15 and 12 miles per hour, respectively. The previous chassis are unchanged.

WILLYS-OVERLAND—The 800-pound chassis has an increased wheel hase, three-quarters floating axle, larger hrakes and increased equipment, which includes a self-starter.

Contrast The Motor and

Oval—The motor trucks sailed majestically along the snow-swept streets
Right—Extra horses were necessary to pull heavy loads after the storm
Upper Left—The wagon crew often had to put their shoulders to the wheel
Bottom—Deep in the drifts, the driver had to help the horse turn

Delivery in the

WHEN the avalanche of snow descended upon New York City Christmas Eve, it found the holiday delivery business just passing the peak of the load. When the storm was at its height, the volume of deliveries was on a lessening scale and the crux of the storm was too late to do any serious harm to the delivery systems at large. Nevertheless, the managers of most of the delivery departments of the big department stores declared that the motor trucks in their service were of primary importance in clearing up the holiday rush. On the slippery pavements the horses were unable to keep their feet and strained in vain to draw the heavy loads, while the trucks majestically sailed on their way, unhampered by the drifting snow and the treacherous traction.

But, from the beginning of the snowfall until the last of the Christmas Eve deliveries was made, something over 1,000,000 packages were carried from retail stores to consumers within the delivery districts. It is estimated by the delivery chiefs of the department stores that the packages averaged 5.5 pounds, and thus the total amount of Christmas busi-

Pictures the Horse —

Christmas Storm

ness done by the delivery systems during the storm was 5,500,000 pounds or 2,750 tons.

Throughout the storm these motor vehicles did yeoman service. Some of them were used continuously for full 24 hours, though the average service of the whole battery of trucks in use has been estimated at 18 hours

Only one complaint was made on account of the truck service. Traction in the falling snow was uncertain and the demand for chains exhausted the supply in 2 hours. This led to some astonishing makeshifts to prevent skidding and to obtain traction. Bits of carpets were bound upon tire treads; impromptu chains were hastily forged at blacksmith shops; ropes were pressed into service pretty generally and the business was moved.

The use of non-skid devices on trucks is a subject that has caused a large amount of debate in the automobile industry. Advocates of chains state that they are necessary in light snow and others hold that a very large truck under load does not require chains under any conditions.

They also declare that a good driver does not need chains to the

Oval—The way the motor trucks bowled merrily along in spite of ice and snow
Left—It took as many men as horses to deliver a load of coal in the storm
Upper Right—Every few moments traffic would be blocked by a fallen horse
Bottom—Even when the wagon was empty the horse could not keep his feet

Fixing up a strained trace at Columbus Circle

The panel of three pictures shown above gives an idea of the difficulties which the drivers of horse-drawn wagons had to conquer in order to make deliveries

same extent that the novice or careless driver requires them. Nevertheless, the rush for chains was a concerted movement when the snow began to fall. Not only that, but the reports of stalled automobile trucks fails to include any mention of one which was equipped with chains that fitted the tires.

With the horses there was a very different story to tell. During the hours when the snow was unpacked, those that were smooth-shod floundered and fell in all parts of the city, as shown in the accompanying illustrations, and where the streets are paved with granite or other unyielding surface matêrial, it did not matter whether they were rough-shod or not. After the snow packed, the horses which had calks in their shoes did better but the service was considerably delayed in spots.

Systems of transportation in New York are divided into three classes on an equipment basis. First, the fully motorized systems; second, the mixed systems and third, the exclusive horse systems.

There was no trouble to speak of with the first named class; a small amount of difficulty, mostly due to temporary delays in the second and a considerable amount with the last.

From noon of December 24 guaranteed delivery was not universal among the New York stores as it usually is on that day. No formal notification was published for the guidance of salesmen not to promise deliveries within the day, but the word was passed around in some of the stores that rash promises of delivery should be avoided and that the word confident should be substituted for the word guaranteed in all delivery promises.

Fortunately weather conditions so shaped themselves that the deliveries were actually made, although in some outlying districts Santa Claus arrived after midnight.

Some of the leading houses had the following to say about the Christmas deliveries in relation to the storm conditions:

Greenhut-Siegel Cooper Company: Deliveries slowed up after the storm was over, but not sufficiently to cause disappointment to our patrons in the matter of Christmas deliveries. We retain the horse as motive power for our deliveries in large proportion, although the department includes a large number of automobiles. We were obliged to double our horse equipment during the snow, but fortunately we were in position to do so with little disturbance of the system. Everybody met with some delays during the day and night.

Macy's: The delivery chief said: We use 450 horses and 55 automobiles of various types. The horses are used for central work and to distribute from our suburban depots

The big motor busses covered their route with no trouble

and the automobiles for the heavy long-haul work. We had no trouble as the storm broke too late to catch us at the height of the holiday deliveries.

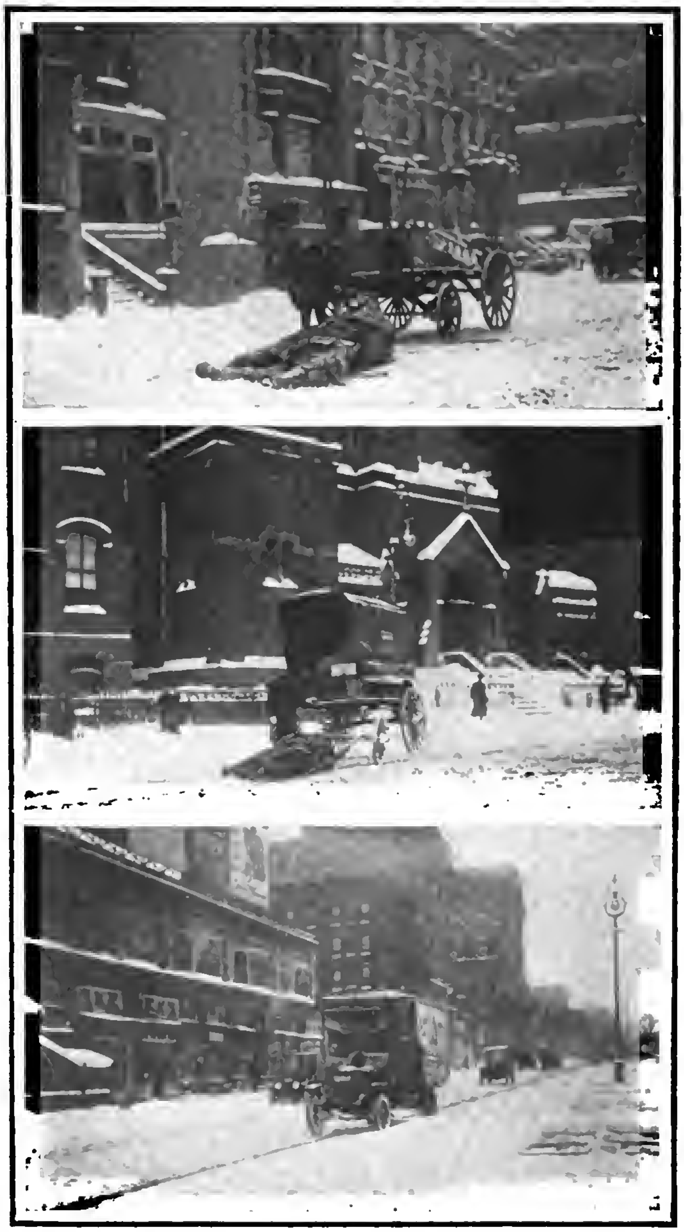
Gimbel's: Captain Mabie, chief of transportation, said: Gimbel's is completely motorized and our equipment proved adequate although it was worked to its full capacity. We had some trouble, but nothing out of the ordinary. Working out from the store, warehouses and depots under full load the drivers reported no delays, but in certain cases where chains were lacking the empty cars had some trouble in returning on schedule. Compared with other storms where mixed equipment was used, the showing Christmas Eve was excellent.

W. & J. Sloane: Our battery of eighteen Whites and five General Vehicles performed splendidly under the heavy business and weather conditions of Christmas Eve. It would be foolish to say that the business was handled under the storm conditions as any ordinary day's business could be handled, but our patrons have made no complaint, which is the real measure of the situation.

Wanamaker's: If the storm had come along 24 hours before it did, deliveries generally would have been delayed to a greater extent, but it was withheld long enough to remove its sting. Under ideal weather conditions, Christmas business must be slower in delivery than ordinary business, because of its volume. When a storm intervenes there must be some delay. Luckily we had no more than our share, which was little.

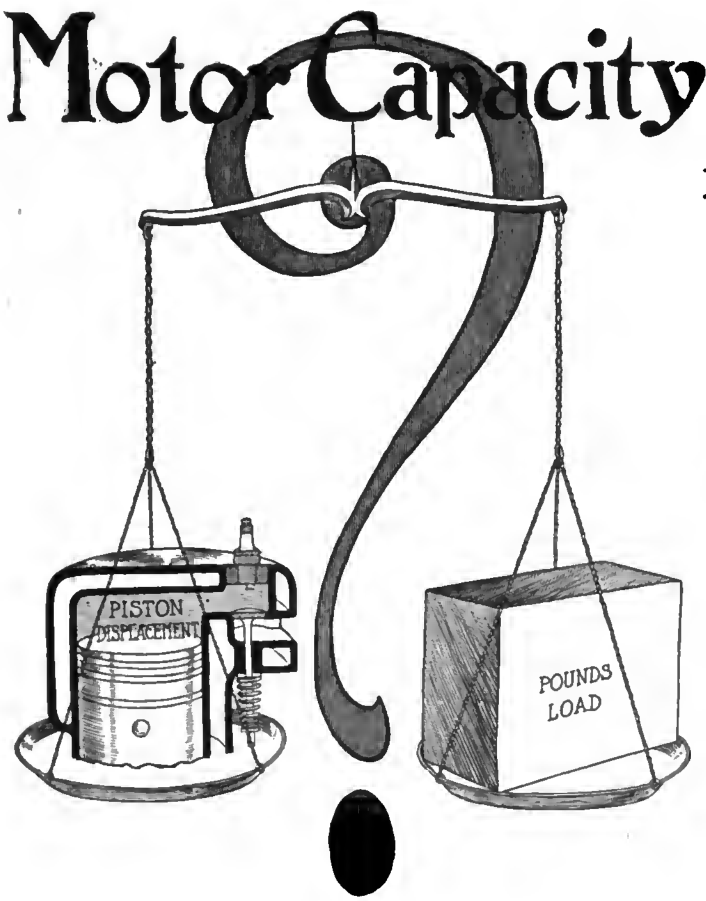
Burns Brothers: During the height of the storm an order was received for the immediate delivery of 54 tons of coal from one of our North River pockets to a customer on the east side of town. Three of our 10-ton Hewitts were available for the job and three three-horse teams hauling 8-ton wagons were standing in the shed. The six vehicles were loaded and each automobile was assigned to a wagon as a helper. The six started out, but before they had gone far the drivers of the horses signalled for help and the fleet went through Forty-second street with the automobiles towing the horse trucks. During the run the horses had all they could do to keep their footing, but the heavily loaded automobiles did not require chains.

John E. Morrell & Co.: We used electric trucks in our delivery service on Christmas Eve, and while we experienced some delays as the traction was very bad, the power wagons handled the business. Compared with former years and storms where we used horses, the showing during the holidays was excellent.



When the horses fell, exhausted by their struggle on the precarious foothold afforded by the icy pavements, it was often a hard task to get them to their feet

Motor Capacity—Load Ratios



Describing by Charts and Tables How Different Makers of Trucks Have Met the Situation, Showing Considerable Diversity of Opinion

OWING to the varying conditions under which trucks operate, there is bound to be a wide difference of opinion as to the proper relation of horsepower to useful load. The rated horsepower is no criterion to form a basis of calculation, as the accepted formula in use at present does not take the stroke or revolutions per minute directly into consideration. This being the case, the next best method is to take some common unit as piston displacement in cubic inches and compare it to the useful load capacity of the vehicle. In fairness to the makers it may be well to state at the outset that motors are not fitted to trucks without any regard to general economy. Economy and efficiency are the two desiderata of the truck user. The question of the size of the engine as compared with the useful load has been a much-debated one for some time past and the following tables and charts have been prepared, from data furnished by individual makers, for the readers of THE AUTOMOBILE, to show the present trend of affairs rather than to show directly or by inference what the best ratio should be. It would be necessary to know many things in order to attempt to criticize, and even then, any conjecture might fall short of the actual conditions.

While the truck business generally has grown by leaps and bounds in the last few years, there have not been enough data for engineers to go upon to determine what the best ratio should be. On the one hand there is the maker who fits a large engine and claims greater all-round efficiency despite increased running costs due to a larger consumption of oil and gasoline, but the mere fact that the engine is large is not a proof that the consumption will be high. The maker who fits a comparatively small engine with a high ratio of useful load to piston displacement probably has a better showing upon consumption than his larger competitor. But how high should this ratio be so as to insure the motor from being overloaded or, in other words, breaking its back endeavoring to carry the load?

In this connection conditions of service are the main factors to determine the question. It would be safe to assume that it would take less power to drive a pneumatic-tired truck than one

Load Capacity and Piston Displacement of Trucks Under 2000 Pounds

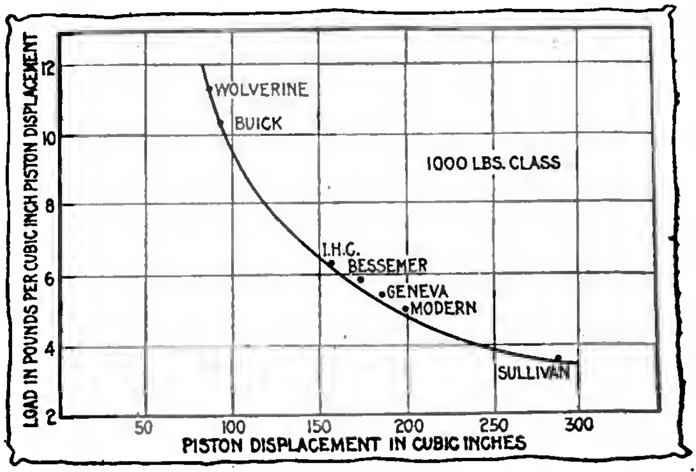

Fig. 1—Chart showing ratio of load to piston displacement for trucks of 1000 pounds capacity and under

fitted with solid tires; also that a truck running on level roads would perform better with a comparatively small engine than with one of more power that it was necessary to keep throttled down the best part of the time. Truck users have themselves to blame in some cases for apparent lack of efficiency. There has been a desire on the part of some to make a 2-ton truck do the work of a 3 or even a 4-tonner, and with the overload expect the same maximum speed that was intended for the rated capacity. Truck makers are entirely at the mercy of their customers in this respect and with a better understanding of the overload and overspeeding situation there is a possibility of a reduction of the power at present existing to a conservative average that will bring with it a more economical vehicle.

Under 2,000-Pound Class

¶ The chart for this class, Fig. 1, shows the ratio of useful load in pounds per cubic inch of piston displacement of seven vehicles. The first two vehicles have one and two-cylinder engines respectively, which fact naturally gives them a small piston displacement. The largest truck, the Sullivan, has a small ratio in the 1,000-pound class, but by referring to the table for vehicles under 1 ton it will be found that the same size engine is used in the 1,500-pound chassis as well. Its relative position is also shown on the 1,500-pound chart, Fig. 2. This chart has been plotted from the figures of twenty-five vehicles and while the ratio stretches from the 14-pound to the 5-pound line nevertheless the greater proportion lies in between the 6 to 8-pound lines. In other words, the general average ratio is 6 to 8 pounds useful load per cubic inch piston displacement. All vehicles above the 8-pound line, with the exception of the Available, which has a four-cylinder motor, are fitted with one or two-cylinder engines. No doubt the motor capacity of this class has in a measure been influenced by pleasure car practice, the available data being sufficient to form a foundation to work upon.

2,000-Pound Class

¶ The average horsepower for this class is approximately 25, according to S. A. E. rating, and the average ratio is 8.47 pounds load per cubic inch of piston displacement. The elongation of the curve for this category, Fig. 3, is caused by the fact that several makers who cater to this class fit the same engine in the next heavier class that they do in this case. When the reason for this is inquired into it will be apparent to any one that the 1-ton truck is expected to go faster than the 2-ton, consequently the gear ratio will be higher and therefore requiring more power to drive it. The concentration of effort upon one motor also is cheaper for the maker and in the case where a truck user has several vehicles of one make, for example, some of the 1-ton and some of the 2-ton types, parts for one will fit the other, which is quite an item when the repair question is taken into consideration.

The general average ratio above stated can be realized by referring to the chart, Fig. 3, which shows that a number of makers use the same size engine, with a piston displacement of 231.9 cubic inches, while several more use an engine with 226.2 cubic inches piston displacement. The two largest, namely, the Mack and the KisselKar, have the same rated horsepower, the bore in each case being the same, but the stroke of the Mack is .5-inch longer, giving the motor 16 cubic inches more displacement, and .3 pound load less per cubic inch displacement.

3,000 to 4,000-Pound Class

¶ These classes are so inter-connected that it may be well to deal with the two capacities as a whole from the point of view of averages. Reference to the table will show that several makers fit the same size of engine to the 3,000-pound chassis that others use in the 4,000-pound. In order to differentiate between the classes two separate curves have been plotted.

Taking the two classes as a whole, there are fifty-three makes represented, which is by far the greatest number for any class.

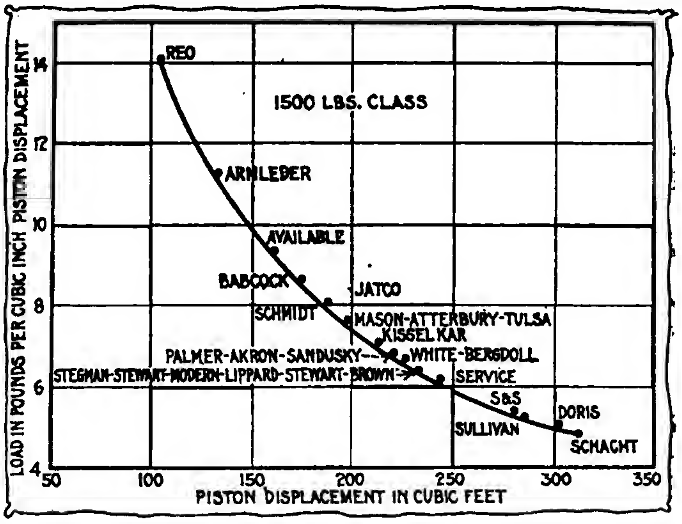

Fig. 2—Chart of the 1500-pound class, showing a decided tendency in load displacement between 6 and 8 pounds per cubic inch

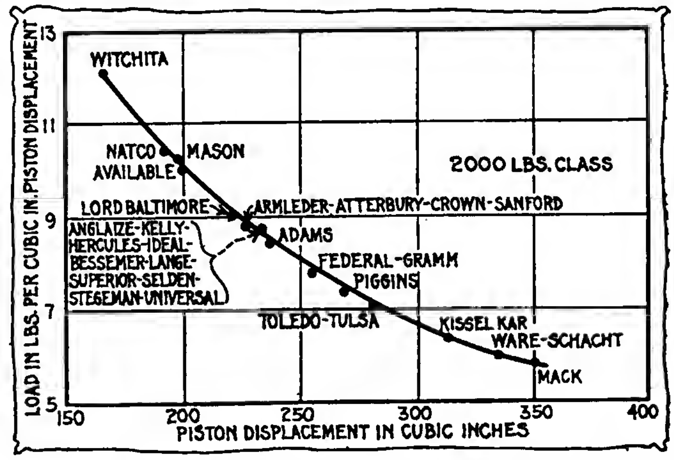

Fig. 3—Chart of the 2000-pounds class, a feature being that 10 makes of trucks are fitted with the same size engines

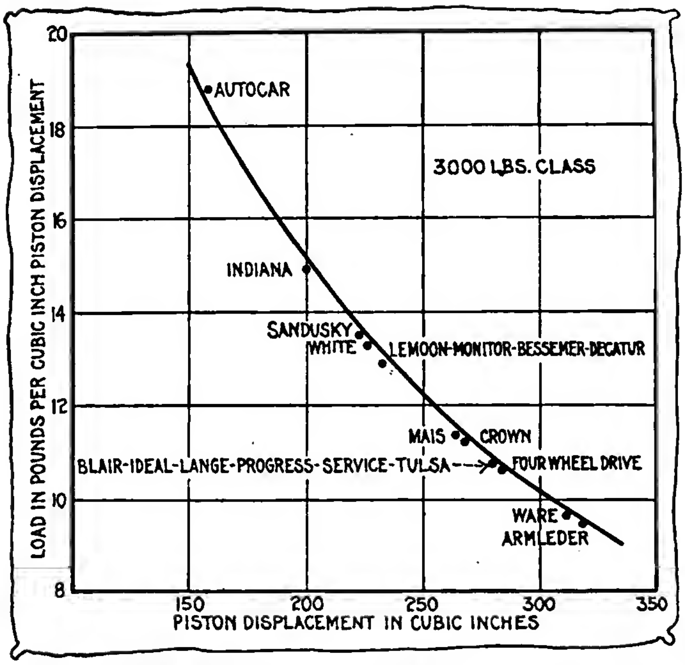

Fig. 4—The chart of the 3000-pound class shows two distinct tendencies

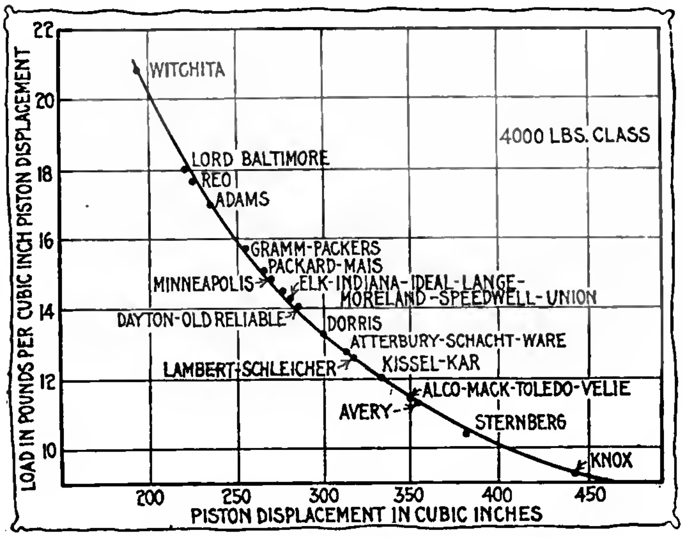

Fig. 5—The chart shows that the 4000-pound class is well represented

Of this there are thirty-four 2-ton models. The average horsepower is 28.8 and the average ratio of useful load in pounds per cubic inch of piston displacement is 13.16.

The Knox is fitted with the largest engine, having a piston displacement of 431.9 cubic inches, the ratio of which is 9.3 pounds useful load per cubic inch. This same size of engine is used in the Knox 3-ton chassis.

The average bores of the engines of this class range from 4 to 4.5 inches, the strokes varying from 5 to 5.5 inches.

5,000 to 6,000-Pound Class

¶ This class is represented in the tabulation by thirty-three models, four of which are 5,000-pound capacity and the rest 6,000-pound trucks. The horsepowers and load displacement ratios differ considerably, as can be seen by the length of the curve in Fig. 6, so the average horsepower is the best criterion for the class, this being 32.69, and the average ratio 17.76 pounds useful load per cubic inch of piston displacement. The chart, Fig. 6, shows that the piston displacement of the majority of the trucks is between 350 and 400 cubic inches and the ratio

of load lies between 14.5 and 17 pounds useful load per cubic inch piston displacement.

The largest engine in this class, the Mack, is another example of the same size engine used in several classes. The 3-ton chassis does not have to be built extremely heavy and, while so many makers have not catered to it as the 1.5 to 2-ton type, or even the 2-ton type alone, nevertheless the size is one that is popular, it being the happy medium between the light and the heavy class. It is adapted to the long-distance haul, wherein lightness is an advantage and the motor has a better opportunity of turning over at a more even speed than in city work where traffic stops necessitate considerable fluctuations in the revolutions per minute and constant speed changing. The average horsepower for this class is 32.5, there being ten makers out of the thirty-three herewith scheduled who fit larger engines than the average.

7,000 to 8,000-Pound Class

¶ This class has not attracted as many makers as the one below it, namely, the 6,000-pound nor as many as the next larger, the 5-ton class. Eighteen models are represented in the tabulation, eleven belong to the 8,000-pound and seven to the 7,000-pound classes. With few exceptions the piston displacement of this class lies between 320 and 420 cubic inches. In order to strike a general average the class has been taken as a whole, the average horsepower being 34.4 and the average ratio of useful load is 20.55 pounds per cubic inch of piston displacement. The chart, Fig. 7, shows two curves, one for the 7,000-pound and one for the 8,000-pound chassis. In the 7,000-pound class the Alco has the largest piston displacement with a ratio of 14.3 pounds useful load per cubic inch displacement and the smallest, the De Dion Bouton, with a ratio of 23.3 pounds per cubic inch. One point that has not been mentioned so far is the question of engine speed and gear ratio. Quite aside from the question of piston displacement these two features have a direct bearing one upon the other, as well as upon the cylinder contents.

8,000 to 10,000 Class

¶ From the 8,000-pound chassis upwards the power of the motor is influenced, not only by the load to be carried, but also by the total weight of the chassis as well, the work to be performed and the nature of the country in which the vehicle is to operate. There would not be any advantage in fitting a motor larger than the average for this class, namely, 35, if the truck were intended for level roads, but this rated power might prove entirely inadequate, as it has in some cases, in very hilly districts. A more powerful motor would not only be advisable under certain circumstances, but sometimes imperative.

10,000 Pound Class

¶ This class covers twenty-three makes of trucks in the tabulation, all rated at 10,000-pound carrying capacity. The 5-ton truck has attracted many of the most prominent concerns in this country, and while it may be said that the greater number favor a motor with a piston displacement of between 400 and 500 cubic inches, yet there are ten makers who fit smaller motors and four who fit larger ones than this average. The average rated horsepower is 37.44, but this is below the horsepower actually developed. For an example of this one only has to look at the upper end of the curve and compare the four smallest engines. The White and the De Dion are rated the same but there is a difference of 14 cubic inches in displacement, as the De Dion has a longer stroke. The piston velocity in feet per minute might show an entirely different aspect as also would the gear ratios. The Vulcan is rated at 30.65 horsepower, while the Knicker-

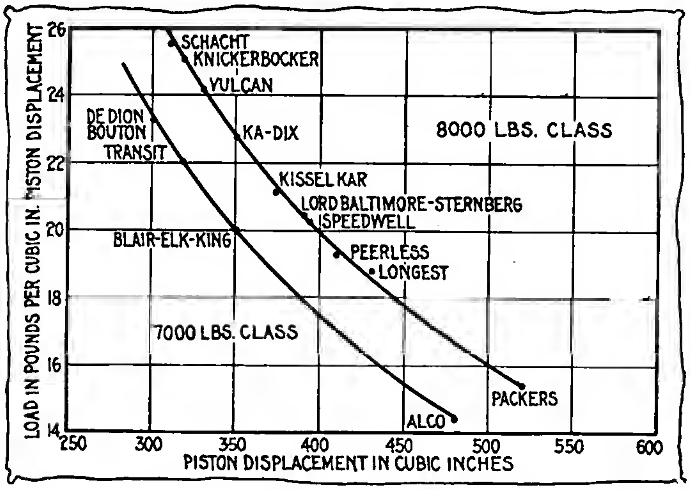

Fig. 7—The 7000 and 8000-pound classes, charted together, showing a slight variation in load-displacement ratio

bocker is rated at 32.4, and, when piston displacement is considered, the Vulcan shows 14 cubic inches more.

The curve, Fig. 8, is a very interesting one as it shows the differences of opinion of the designers of the various makers therein represented. It must be admitted that a variation between 32 pounds and 14 pounds useful load per cubic inch of piston displacement is a very wide range, but on carefully analyzing the chart it will be seen that there are only four makers who run below 21 pounds, so that in point of fact the range is nearer 20 to 30 pounds.

11,000 Pounds and Upwards

¶ Trucks with a load capacity of 10,000 and upwards must necessarily be made heavy to carry the weight of the load and when the weight of the body and chassis are added it is no uncommon occurrence to find that the combined weights total 20,000 pounds and over. Engines with 5-inch bore seem to be the general average for this class, and as the speed of these vehicles must necessarily be restricted if the tires are to last any length of time irrespective of the excessive vibration that is engendered above a certain speed which is most detrimental to the entire mechanism, this size of motor should seem to be ample for most conditions. The solution of the load displacement ratio problem in the case of this class seems to lie in the degree of efficiency of the motor and the correct speed reduction ratios, be they in the gearbox or the final reduction at the sprockets. The initial effort to move this weight from rest must involve a great strain upon the entire mechanism and as speed is not the main factor, general efficiency is more to be sought. This class of truck is primarily intended for the short to medium haul and its handling must be understood in order to obtain satisfactory results.

In order to show at a glance the variations in motor capacity as compared with load ratio in the various classes of trucks Fig. 9 has been prepared. It will be noticed that the curves representing the different capacities are more or less the true arcs of circles and in many cases these have a common radius.

While it is true that a small motor may be more efficient than one considerably larger or a large motor may be more economical than a smaller one of a different make, nevertheless, in order to understand the question of motor capacity as compared with load ratio, it will perhaps be better to strike a general average. It cannot be stated too emphatically that piston displacement *per se* is not the most important factor in engine analysis, as by it alone very little can be determined. It must be presumed that other conditions are equal, such as engine speed, compression, valve area, carburetion, ignition and transmission efficiency. With this clearly in mind, the accompanying tables have been analyzed and the following figures obtained showing the average S. A. E. rated horsepower and the average ratio of load in pounds per cubic inch piston displacement for the various classes of trucks for 1913.

Load Capacity and Piston Displacement of Trucks of 10,000 Pounds and Over

The Gasoline Truck

Trucks and Delivery Vehicles Classified According to Load Capacity; Price and Body Sizes

Facts for the Buyer

THE field of commercial vehicles has considerably broadened during the last year and at present the buyer has a greater variety of offerings than heretofore. Despite the fact that several makers have abandoned truck manufacture there are, in round figures, twenty more makers listed herein this year than last. The number of models has also materially increased by about 100.

The 1-ton class finds the largest number of adherents, next to which in point of numbers comes the 3-ton class. The 2-ton class, with forty-eight models, ranks third. The 5-ton category shows a total of forty-five models, the same number being true of the 1,500-pound class. There are thirty-four types of chassis offered in the 1,000-pound class, ranging anywhere from the 400-pound utility wagon to the 1,000-pound inclosed panel body style.

There seems to be considerable diversity of opinion upon the matter of price, and owing to the considerable variations that will be found by a careful scrutiny of the tabulations the buyer's choice will largely depend upon the peculiar conditions met within his business as to his requirements.

The general average price for the 1,000-pound wagon is anywhere between \$750 to \$850. The 1,500-pound wagon, however, does not seem to offer any happy medium, as one make of car lists around \$800 whereas another with the same capacity lists at \$2,500. The general average of prices runs between \$1,400 and \$1,700, naturally with some above and some below these figures.

The 1-ton capacity class which has already been mentioned offers the buyer the greatest choice from the point of view of number of models. The prices range from \$1,000 to \$2,250 with perhaps a mean average of \$1,750 to \$1,800, for the chassis.

The 3,000-pound class is not so important from the point of view of numbers as the 1-ton. The prices range from \$1,750 to \$3,000 with a mean average of \$2,400. The 2 to 2.5-ton class ranges between \$1,800 and \$3,500 with an average of \$2,800 to \$3,000. The 3 to 3.5-ton class ranges between \$2,700 and \$4,000 with an average of \$3,400 to \$3,500. The 4-ton class ranges in price from \$3,200 to \$4,500, averaging slightly less than \$4,000. The 5-ton contingent range between \$4,000 and \$5,000 in price, with a few selling for less than \$4,000.

Educating the Freight Automobile Driver

Drivers Must Be Taught Operation and Care of the Automobile Mechanism as Well as Delivery Business—Factory and Private Schools and Traveling Demonstrators Instruct the Former Horse Drivers

TO GET the best possible service out of a freight automobile two things are necessary, namely, a truck as perfectly as possible adapted to the specific requirements of the owner's business and a driver equally qualified. The motor truck driver, his selection and his education arc the subject of the following article.

The situation has three angles, the selection of the man best fitted for the position for which he is chosen, the education wich must be given to the man to suitably prepare him for his driving and delivery work and, finally, the best method of imparting his education to him. These three points of view may again be subdivided as follows:

1. **Selection of best men:**
   a. Ability and general qualification.
   b. Character.
   c. Age, physical constitution, etc.
2. **Subjects of education:**
   a. Knowledge of the truck, its construction, troubles and repair.
   b. Care of truck, operating speed, etc.
   c. Correct way of loading the truck.
   d. Delivery work.
   e. Economical training.
   f. Moral training.
3. **Methods of education:**
   a. Schools conducted by truck makers.
   b. Work of companies' instructors and demonstrators.
   c. Instruction by experienced truck drivers in owners' employ.
   d. Specially organized schools.

The selection of the men who are to serve as truck drivers must be in the hands of a person fully familiar not only with the construction and nature of automobile trucks, but also of the business in which the machines and their drivers are to be used. A general inquiry among men of this nature has brought out the astonishing fact that the most important quality which makes for a good driver is industriousness coupled with common sense, rather than years of experience with automobile mechanisms.

The majority of men who have had vast experience with truck drivers are unanimous in stating that the best type of truck driver comes from the ranks of the former horse vehicle drivers taught to handle a freight automobile.

The reason for this fact is that a horse driver who is familiar with the delivery business of a certain company will be much easicr educated to a truck driver and familiarized with the requirements of an automobile than a chauffeur will learn the delivery business, as this business requires a long and steady training and a good man must have a high degree of responsibility to be worth his wages. This brings us to the critical point of the situation. Chauffeurs of pleasure cars are liberally paid, and often command much higher incomes than truck drivers, although the work of the former is in many cases easier and more pleasant than that of the latter. Consequently there is no inducement for a good chauffeur to come down to the pay of truck driver.

Another point upon which great stress is laid by men who know is the fact that pleasure car chauffeurs are, as a rule, not such hard-working men as truck drivers must be in order to be efficient. The hours of the averagc chauffeur who drives a pleasure car are short when compared with thc working time of a motor truck driver and such an occupation as that of the former does not tend to make a man ambitious and hard working. A man who has worked as a pleasure car chauffeur for any length of time generally begins to consider himself an aristocrat among his fellows and would deem himself degraded if he had to step down to the harder work of the delivery driver, which is not even paid as well. Add all the little pleasures that go with the profession, so-called, of a pleasure car chauffeur, such as a neat livery, the occasional use of the car for his own devices and the consequent social successes, there remains little or no incentive for a chauffeur to join the ranks of his truck brothers. Furthermore, the chauffeurs' profession has occasionally been a goal for capable but morally irresponsible characters whose influence has made itself known at least by the general desire for private gain, which sort of egotism cannot be satisfied if a man works as truck driver. The little niceties which count in the person of a pleasure car driver, such as an attractive exterior and gentlemanly bearing, are likewise superfluous in a truck driver and therefore not paid for by a truck owner and operator.

A former horse driver, on the other hand, improves himself, however slightly, when he advances to the ranks of a truck chauffeur. The improvement is financial as well as moral, since most people's self-consciousness is elated upon changing from the operation of a quadruped to that of a mechanism which does so much more work in a shorter time and, once known in its habits, may be easily governed by the man who knows. The knowledge of the truck mechanism opens, furthermore, to the ambitious man the road to the chauffeurs' profession, to the position of a delivery superintendent or the like, all being factors which tend to make a good man put his best efforts into his work.

It goes without saying that a certain physical ability is requisite for a man's being eligible to the truck drivers' ranks. As a rule, a man who is capable of handling a pair of horses will be physically able to cope with the freight automobile after having been taught the mechanical requirements of the latter. In this connection the age of the man is frequently among the principal factors considered. One of the largest express companies of this country, for instance, only uses men ranging from twenty-one to forty-five years of age, for either the work of the driver or the worker. Men above forty-five after twenty years or so of this sort of work are naturally not quite as quick as when they took it up; nevertheless in a great many cases their accumulated experience and grown brain capacity makes up for this defect, and it is doubtful whether such a hard and fast rule is a better course to adopt than a decision from case to case.

Coming to the second division, the subjects of the driver's education, the knowledge of the automobile and an understanding of its construction and needs seems to stand foremost. It stands to reason that it would be a very expensive process to let a driver take out his truck and if he meets with an accident or slight misadjustment of some part or other of his truck, 20 miles away from the garage, to telephone for a mechanic, merely to have the latter go over the spark-plugs or to locate a short-circuit in the ignition wiring. It is ever so much cheaper to instruct a driver before entrusting him with a truck how such minor troubles may be remedied without calling on the aid of an expert. A phase of the education which goes hand in hand with this is to make the driver familiar with the proper care of the freight automobile. The driver should know at what speed he may safely operate his truck over various kinds of road. He should also know the details of lubrication, of keeping the cooling system well filled with water, and so forth.

One point of the education which is half mechanical and half of a delivery-business nature is the proper method of loading a truck. The driver when being instructed should be informed how much weight should be loaded on the various portions of the body and how this should be done to permit of efficient and rapid unloading and delivery. Whatever information is necessary to bring out the points upon which depends the high or low cost of truck operation should be imparted to the driver. He ought to be taught to avoid tire abuse, to properly use and not strain his brakes, to use the motor as a brake in coasting down a hill, to use the top gear whenever possible and to apply every known process to get as much work as possible out of the given quantity of fuel. To complete his education the owner or his representative should instill some definite moral ideas into the men which would tend to make them good workers and to which they would live up if the lessons are brought home in the right manner and spirit; the latter, of course, requires deft work, but the success of various firms operating on modern principles has shown that moral education of the driver pays.

The practice of a truck maker conducting a gratis course for the men who are to drive the trucks manufactured by them is making headway, although not as rapidly as might be expected. It has been proven, however, that the companies who introduced such a school for the benefit of their customers have been amply repaid for their efforts by the reduced measure of trouble encountered with their product later on. In these schools men who are to drive the trucks and are sent in by the buyers of the latter are given a sufficient knowledge of the mechanical side of the truck and the various requirements of the latter, this instruction work taking place in the shop. A little later the men are generally taken out on the road and shown how to drive and how to make repairs in case of trouble.

Other companies, instead of conducting a central school system, send their demonstrators with a newly sold truck, who also serve as instructors to the drivers with whom the handling of the truck is to rest. Some of these companies make also a practice of a periodical inspection of every truck sold and of instructing the drivers on this occasion.

One of the best methods conceivable is the following which, however, can only be used where a number of motor trucks have been in service before a new lot is introduced and a new set of drivers must be educated. **This system is used by some of the largest express companies in New York. It consists in using the most experienced of the companies' drivers as teachers for the recruits, who in this way not only become acquainted with the mechanical side of truck driving, but also get a good idea of the delivery work, the loading problem, etc.**

Finally there are especially organized private schools who teach the men all the things mentioned above.

Following are a few excerpts from letters received by THE AUTOMOBILE in reply to an inquiry as to the stand they are taking with regard to the question of automobile instruction for truck drivers.

What Truck Makers Think of the Education of the Truck Driver

ARDMORE, PA.—The system that the Autocar Company uses in instructing drivers allows for taking a horse driver off from a wagon, putting him through the Autocar course, and turning out a very capable driver. As a matter of fact, we have turned out in Philadelphia alone 1,400 drivers in the past 2 years. It is an earnest desire of the Autocar Company to co-operate at all times with the users of Autocars, who are invited to send their drivers to school in Philadelphia, New York and Boston, where free instruction is given on the care of the cars.—THE AUTOCAR COMPANY.

MOLINE, ILL.—Men are placed on the assembly floor of the Velie factory that they may notice the location of every part, grease cup, etc., and instructed in theory as to the operation of trucks; as a result we find their efficiency much increased and at the same time making better their operation of the truck and its decreased depreciation. The idea has been confined largely to the adjacent factory territory.

We think that idea of training schools in various cities for the education of truck drivers is fine. We believe that all truck manufacturers would be interested in such a proposition.—VELIE MOTOR VEHICLE COMPANY.

SPRINGFIELD, MASS.—The Knox Automobile Company has done a great deal of work of this sort in connection with handling our fire apparatus particularly. Firemen as a rule know very little about automobile motors, to say nothing about the requirements in handling fire trucks, so it is necessary to give them a very thorough course. They are generally men picked for some slight mechanical intelligence.

We start them generally on the motor assembly, where they learn how the motors are put together, as well as the major adjustments. They then go on to the chassis assembly, and finally to the testing department. Here they learn the handling and control of the car and the minor adjustments, thus following their own cars right through the shop.

We believe it would be the height of foolishness to put expensive machines of this sort into the hands of untrained men, or even to risk having them operated by local drivers who might have had driving experience on certain cars but not on ours. This particular arrangement is expensive to our factory and is a source of considerable hindrance to our employees at times, but we find it pays in the long run, and it enables these green men to become much more proficient in handling and taking care of our cars.—KNOX AUTOMOBILE COMPANY.

NEW YORK CITY—The Alco company always has experts available to instruct a driver employed by any of our owners in the operation and care of Alco trucks. This form of service is supplemented by service in the way of sending experts along on the trucks with the new drivers until they become proficient. Furthermore, our inspection system aids the drivers, as we keep in touch with them. Traveling inspectors make the rounds and give drivers the benefit of their advice in such matters as operating economically, proper distribution of loads and general care of the vehicles.—AMERICAN LOCOMTIVE COMPANY.

MINNEAPOLIS, MINN.—The former horse driver makes the best truck driver, but it takes some time to get him properly trained so that he can take care of the mechanical parts. We believe the best method for training this kind of driver is to bring him into the shop and train him for 2 or 3 months until he gets acquainted with the operation of the truck. He then makes a most efficient driver.—H. E. WILCOX MOTOR CAR COMPANY.

FREMONT, O.—The Lauth-Juergens Company believes that it would be a splendid idea if schools were established, providing those attending the schools could get the proper training, not only as to driving of the truck, which is a very small matter, but the detection of trouble, and the ability to repair it, to get that proper training which will overcome his helplessness in case of an accident.—THE LAUTH-JUERGENS MOTOR CAR COMPANY.

NEW YORK CITY—We know of nothing that would help the industry to a greater extent than the establishment of training schools for drivers in fifty or seventy-five of the largest cities in the country. The local auto training schools are not adequate for the purpose, as they have neither equipment in machines nor men to carry out the course of instruction that is of any benefit whatever to the motor truck driver. This is an opportunity for a man of broad mental perspective to further the industry as a whole and himself individually as has never existed in any branch of the motor truck industry. To be of any value, these schools should not only teach the technique of truck driving but they must go into the problem of transportation from the method of handling the goods on the inside of the establishment as well as the inefficiencies of loading and unloading now existing with horse equipment and to a great extent motor truck equipment also.—INTERNATIONAL MOTOR COMPANY.

BUFFALO, N. Y.—As to whether a school for teaching delivery systems would be successful is very problematical. Every line of business has its own peculiarities and details, and it would seem as though it would be extremely difficult to teach a general proposition that would apply to the various lines.—PIERCE-ARROW MOTOR CAR COMPANY.

ELYRIA, O.—The Garford Company has never conducted a class at its factory for educating truck drivers, and we doubt that it will. We have found, however, that the best drivers for motor trucks are found in the ranks of the present drivers of horse-drawn vehicles, and are preferably taken from the force which is to be displaced by the installation of trucks. The reasons for this are many, among which we might say that the most important to the purchaser of the truck is the fact that the driver knows his routes, most of the people to whom he is expected to deliver goods, and is familiar with the methods of doing business.—THE GARFORD COMPANY.

DETROIT, MICH.—The Packard Company in 1907 organized at the factory a school for the instruction of truck drivers in the proper care and operation of Packard machines. The course is 1 month and the class is held from 7.30 a.m. to 4.30 p.m., each day of the week, with 1 hour for lunch. The instructor lectures before the class; then part of the class is taken out by a second instructor for a driving lesson, while the others are examined on the subject taught during the morning.—PACKARD MOTOR CAR COMPANY.

MILWAUKEE, WIS.—We have not to date inaugurated any school for drivers, but have made it a practice to have the drivers of Stegeman trucks come to the factory and give them a thorough instruction in the construction of the chassis, so that they will realize its component parts, their relations to one another and what the operation of different levers actually means. We have found this method very beneficial and is one that should be adopted or followed by every manufacturer.

As regards a training school for truck drivers, this might look good on the face of it, but we are rather inclined to believe that a school of this character cannot long remain independent—that is to say, certain manufacturers will control the instructors and instill into the schools the advantages of certain construction, or in other words, of certain makes of machines.—STEGEMAN MOTOR CAR COMPANY.

Motor Truck Chassis on the 1913 Market

THE AUTOMOBILE Publishes Herewith Its Annual Table of Commercial Vehicles, Covering the Details of Practically Every Gasoline Truck Chassis Produced by Manufacturers of the United States at the Present Time

ON these and the following pages appear the leading mechanical specifications of the various commercial vehicles listed for 1913. These specification tables are based on chassis and not body types. To explain: some of the concerns herein listed with but one, two or three different chassis models may have ten or twelve different bodies, which list of the various body styles of each concern appears in other pages of this issue.

There are a few concerns which do not appear in these specifications solely because it has been impossible to get from them the necessary information on their models. In some cases this has been due to the fact that they are bringing out new ones which they hope to announce immediately after the shows. There are a few concerns which are in more or less uncertain financial conditions and they are not in a position at present to make definite announcements concerning 1913 plans.

This information has all been obtained direct from manufacturers and in places where it is incomplete it has been due to such points not being decided upon. The various columns call for little, if any, explanation. Where optional wheelbases are listed it means that the concerns do this to accommodate the chassis to different body types which call for greatly varying loading platforms.

It is to be regretted that more complete information was not obtainable for the column headed Turning Radius in Feet, as this column refers to the amount of space required to make a complete circle with the vehicle.

†Three wheels. ††Two-cylinder opposed. *Drives on four wheels. †††Gas-electric power plant.

ABBREVIATIONS:—Tires: Solid*, solid dual tires in rear. **Cylinders:** Sep'rt, separate. **Valves:** Opp, valves on opposite sides of cylinder; Head, both valves in head; L & H, left side and in head; R & H, right side and in head. **Camshaft Drive:** Gear, spur gears; Hel'l, helical gears; Spi'l, spiral gears. **Cooling:** Thermo, thermo-syphon. **Radiator Suspension:** S & T, springs and trunnions. **Ignition:** Sing, single; Doub, double; Gov, governor; Auto, automatic. **Magneto or Generator:** Atw K, Atwater Kent. **Fuel Feed:** Grav, gravity; Pres, pressure. **Lubrication:** Spl-Pres, splash and pressure; In Fuel, oil fed with gasoline. **Bore and Stroke:** In decimals to nearest 1-10 inch, as 4.3=4¼ etc., .2=3/16, .1=⅛, .3=¼, .4=⅜, .5=½, .6=9/16, .7=11/16, .8=¾, .9=⅞.

Load Capacity and Complete Specifications

In Calculating the Horsepower of the Motors Given in the Table the S. A. E. Formula Was Followed—That Is, Horsepower Equals the Cylinder Bore Squared, Multiplied by the Number of Cylinders Divided by 2.5

The horsepower given is not necessarily that listed by the manufacturer, but the rating computed by the formula of the Society of Automobile Engineers, which formula is based on cylinder bore and the number of cylinders and only indirectly takes the piston stroke into consideration.

In view of the many requests for gear ratios between the motor and rear wheels it is to be regretted that complete information on this subject was not available because the manufacturers offer such a variety of ratios. The ratio that will suit Chicago is not satisfactory for the same service in hilly cities, such as Cincinnati or San Francisco. Because of this situation wide options are permitted which it would be impossible to list herein.

An interesting column under the head Transmission is that of location, which refers to the position at which the gearbox is mounted in the chassis. Midship means, of course, located by itself at a point approximately midway between the front and rear axle. The other locations are unit with the motor, unit with the jackshaft in chain-driven cars and unit with the rear axle in shaft-driven vehicles.

Under the main heading Running Gear the sub-head Control has reference to whether the steering wheel is placed on the right or left side of the chassis and whether the gear shift lever is on the right side, in the center or on the left side. This also applies to the location and manner of mounting of the emergency brake lever.

†Three wheels. ††Two-cylinder opposed. *Drives on four wheels. †††Gas-electric power plant.

ABBREVIATIONS:—Tires: Solid*, solid dual tires in rear. **Cylinders:** Sep'rt, separate. **Valves:** Opp, valves on opposite sides of cylinder; Head, both valves in head; L & H, left side and in head; R & H, right side and in head. **Camshaft Drive:** Gear, spur gears; Hel'l, helical gears; Spi'l, spiral gears. **Cooling:** Thermo, themro-syphon. **Radiator Suspension:** S & T, springs and trunnions. **Ignition:** Sing, single; Doub, double; Gov, governor; Auto, automatic. **Magneto or Generator:** Atw K, Atwater Kent. **Fuel Feed:** Grav, gravity; Pres, pressure. **Lubrication:** Spl-Pres, splash and pressure; In Fuel, oil fed with gasoline. **Bore and Stroke:** In decimals to nearest 1-10 inch, as 4.3=4¼ etc., .2=3/16, .1=⅛, .3=¼, .4=⅜, .5=½, .6=9/16, .7=11/16, .8=¾, .9=⅞.

† Three Wheel. ††Two-cylinder opposed. *Drives on four wheels. †††Gas-electric power plant.

ABBREVIATIONS:—Tires: Solid*, solid dual tires in rear. **Cylinders:** Sep'rt, separate. **Valves:** Opp, valves on opposite sides of cylinder; Head, both valves in head; L & H, left side and in head; R & H, right side and in head. **Camshaft Drive:** Gear, spur gears; Hel'l, helical gears; Spi'l, spiral gears. **Cooling:** Thermo, themro-syphon. **Radiator Suspension:** S & T, springs and trunnions. **Ignition:** Sing, single; Doub, double; Gov, governor; Auto, automatic. **Magneto or Generator:** Atw K, Atwater Kent. **Fuel Feed:** Grav, gravity; Pres, pressure. **Lubrication:** Spl-Pres, splash and pressure; In Fuel, oil fed with gasoline. **Bore and Stroke:** In decimals to nearest 1-10 inch, as 4.3=4¼ etc., .2=$\frac{3}{16}$, .1=⅛, .3=¼, .4=⅜, .5=½, .6=$\frac{9}{16}$, .7=$\frac{11}{16}$, .8=¾, .9=⅞.

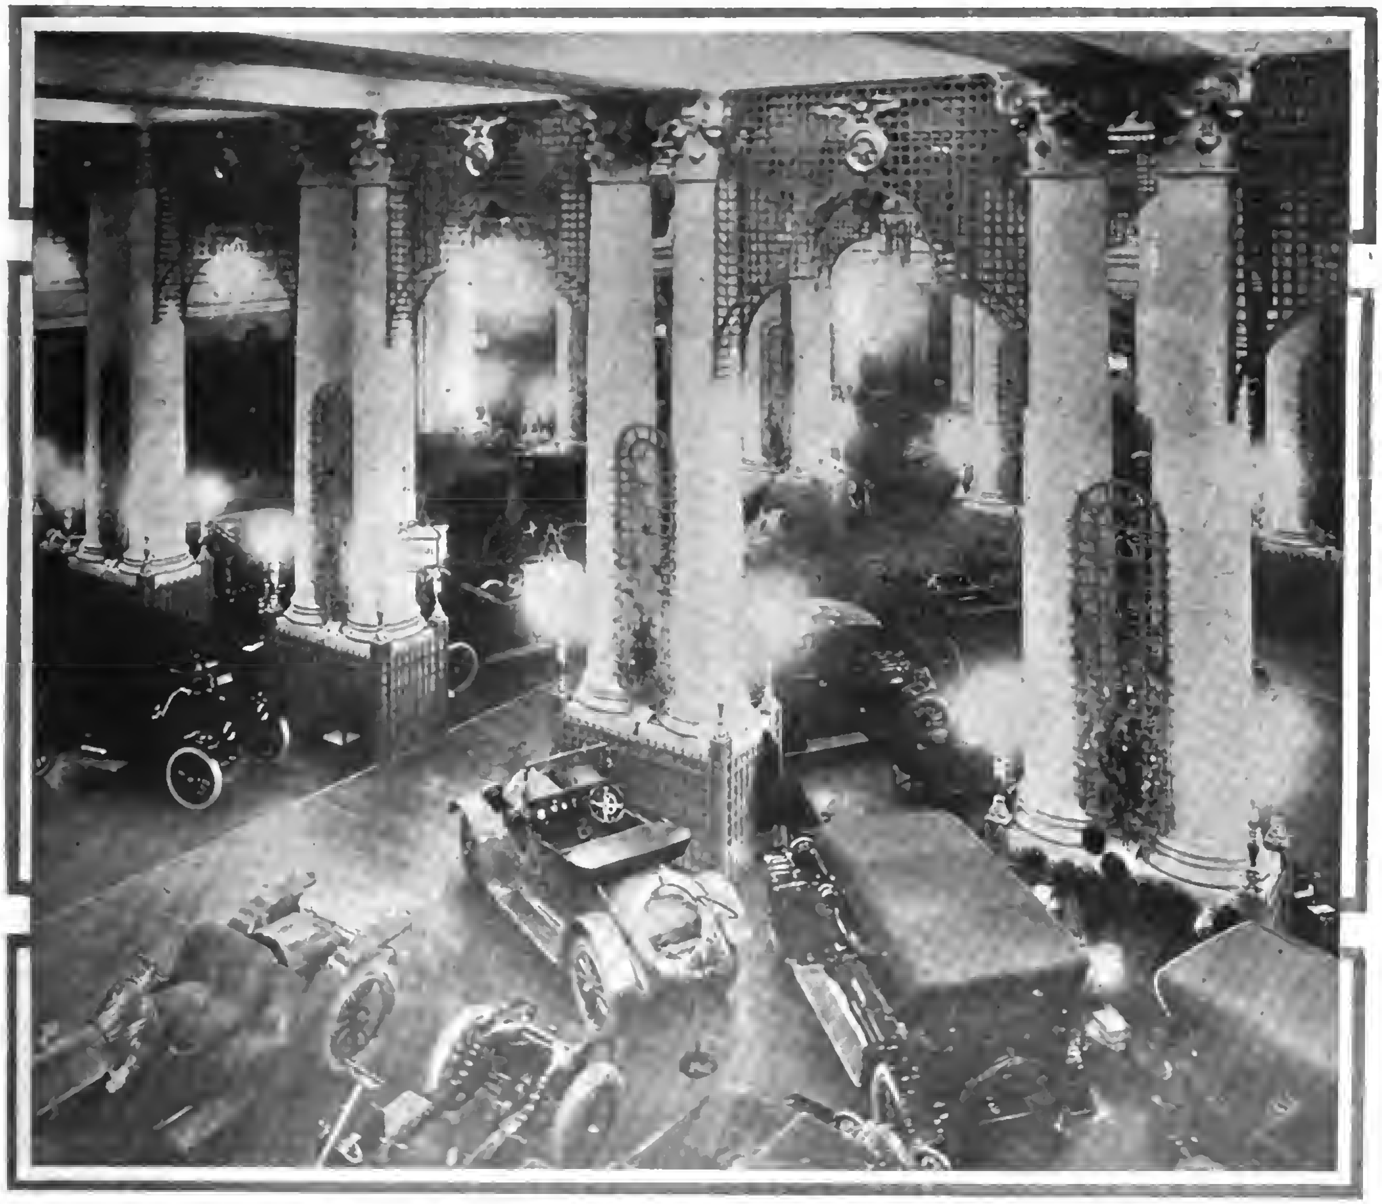
General view of Madison Square Garden, looking towards main entrance. The scheme of decoration is that of a crystal palace with the walls under the gallery continuous mirrors, the gallery faces and pillars in white. The roof studded with brilliant electric chandeliers relieved with flowers. A general profusion of flowers along the face of the second gallery adds a touch of summer to the setting



In the Grand Central Palace the cars are exhibited on two floors. The general scheme of the main floor is shown on this page. The space is broken up by the dual pillars. The scheme of decoration is that of a Viennese garden with a generous supply of lattice work and the walls covered with touring scenes from the different states of the Union, the general decorative effect being exceedingly pleasing

Automobile America at the Shows

Eighty-Eight Different Makers of Pleasure Cars Represented Electric Cranking, Lighting and Ignition Systems in Favor

WITH the slogan "In Two Buildings for 2 Weeks," the largest automobile show yet staged in this country swung open its doors to an exacting public at 8, January 11. For the next 2 weeks the metropolis will be the Mecca of all those interested in the motor car and its relatives. This year both the Palace and the Garden are under the same management and they opened simultaneously. Although no official count of the attendance for the opening day has yet been given out, Secretary Merle L. Downs gave it as his opinion that about 30,000 people viewed the cars and accessories at both the Garden and the Palace on Saturday night.

A few statistics of this, the Thirteenth National Automobile Show, will serve to reveal the magnitude of the undertaking which has been so ably managed by the committee, consisting of Col. George Pope, chairman, Alfred Reeves, and Merle L. Downs. For the pleasure car exhibition there are 467 exhibits, including car makers, accessory makers, and motorcycle manufacturers. At the Garden, where are assembled the car manufacturers who formerly composed the A. L. A. M., which has now passed out of existence, forty-two makes of pleasure cars are submitted to the public, while at the Grand Central Palace, forty-six other makers of pleasure vehicles are holding forth.

So far the attendance has run way ahead of that of last year in both Palace and Garden, although the greatest percentage of increase is at the Palace. As compared with the Paris Salon the combined floorspace of the two buildings used to stage this year's show exceeds that of Paris by 15,000 square feet. The number of exhibitors, although below the total of 565 which exhibited at Paris, when added to the number who will appear for the second week will swell the total to 702.

There are a number of new cars among the Palace gathering. The Edwards-Knight, the Davis, Lenox, the Chevrolet, the Little, the Keeton, have been brought into the fold and installed among their older contemporaries at the Palace. Yet this pleasure at seeing the newcomers is somewhat tempered by the fact that several of the cars which were with us when the industry was young are now absent. Among these may be mentioned the Brush, the Thomas, Elmore, Marquette, Gaeth, Corbin, DeTamble and the Lion.

Of course the electrics this year are few and far between at either building; but this is easily accounted for when it is remembered that these makers decided to be exclusive recently and held a show of their own several weeks ago. Only a few electric makers deigned to appear at the gasoline assemblage, among which more democratic contingent were the Buffalo, Borland, Argo, Church-Field and Standard.

Entering the Garden, we find ourselves in a veritable crystal palace emblazoned with thousands of electric lights and the entire outer wall of the lower floor lined with mirrors. The color scheme is white and gold with many touches of green and red here and there. One idea of the use of the mirrors is stated by the show committee to give an effect of great spaciousness to the already enormous structure. The ceiling is covered with azure material which lends further to the idea of infinite space as of a large slice of sky above the array of automobiles and their parts.

Three enormous crystal chandeliers and many smaller ones add to the decorative scheme and hang from the dome, while along the balconies and the railings flowers are entwined in infinite array. Lattice work adds to the decoration of the flowers and tempers the brightness of the profusion of electric bulbs. A noteworthy feature of the lighting arrangement this year is the placing of rows of lights above each show space under the balcony on the first floor of the venerable Garden. Heretofore some of these spaces have been a little dark, due to the absence of sufficient light with the attendant disadvantages to the exhibitors who wish to show off every feature of their product. But this year there are no unilluminated corners for the many incandescent bulbs take care of this and they are assisted in their work by the mirrors along the side walls at the back of the booths. Indeed so far as light is concerned the management has left nothing to be desired.

At the Grand Central Palace a less expensive decoration is necessary, for the building itself is exceedingly attractive when devoid of any festive dress. It has been converted into a palace of Versailles, we are told. There are great landscape paintings adorning the walls which are assisted in their work of beautification by lattice construction into which flowers have been entwined. These wall panels depict scenes of famous motoring spots throughout the country. The Delaware Water Gap, the Berkshire Hills, the Palisades of the Hudson form the decorations for the walls on the lower floor, while on the mezzanine floor western scenes predominate. Here we see the Grand Canyon, Rocky Mountain canyons and passes and beautiful California views. Everywhere masses of flowers have been used unsparingly. It is hard to conceive a more beautiful effect than that worked out on so extensive a scale for the approval of the great motoring public.

Show space arrangement this year is somewhat more cramped at the Garden and is responsible for the perhaps lower total number of cars shown. There are no machines on the second balcony at the Garden, while the concert hall, lower floor, which was used as an overflow space last year, is not pressed into service this time. In the basement the accessory space has also been curtailed somewhat. At the same time the second balcony has been somewhat widened, which partially compensates for the other subtractions. At the Palace practically all the available space is utilized. Here the car exhibitors have the first floor exclusively, and they also command most of the mezzanine, although a number of

Upper—View down one of the corridors in the Concert Hall. Lower—Accessory exhibits in basement at Madison Square Garden

accessory exhibitors are also seen here. The balcony is naturally devoted entirely to accessories. Space has also been allotted to the motorcycle contingent which appears in connection with the National Shows for the first time.

The attendant social functions and business meetings always in evidence at show time have not been overlooked this year. On Monday a meeting of the executive board of the A. A. A. was held at the Hotel Belmont, while on Tuesday evening a dinner was tendered to the Pioneer Automobile Manufacturers by the Big Village Motor Boosters at the Murray Hill Lyceum at 11 o'clock. On this day also the executive committee of the Motor and Accessories Manufacturers' Association, the finance committee of the same organization and also its board of directors held meetings at their offices on West Forty-second street. The Motor and Accessories Manufacturers were also active on Wednesday, when at 5:30 p. m. at the Waldorf-Astoria they held their tenth annual meeting and a little later partook of their fifth annual banquet.

The social program for Thursday includes a dinner in honor of W. H. Blood, Jr., given by the Electric Vehicle Association of America at Delmonico's, and the first meeting of the midwinter session of the Society of Automobile Engineers at 9:30 a. m. in the ballroom of the Hotel McAlpin. The S. A. E. also holds professional sessions both Thursday afternoon and evening, while on Friday, both morning and afternoon will be devoted to serious work by this body, and in the evening the McAlpin will again be the scene of the annual society dinner. More professional sessions of this society bring the scheduled doings of the week to a close on Saturday.

Although we have mentioned many of the important events which the week has held in store for the visiting automobile hosts, there are many unscheduled entertaining features given by various organizations to members in attendance at the show. All in all, it will be a busy week for those connected with the industry. Many organizations have planned dinners beginning at night after the show closes which, although alive with features for enjoyment, work to the detriment of all-essential sleep.

Decorations at the Garden and at the Palace as well lend themselves admirably to the display of the automobiles inasmuch as they are subdued and harmonize with most any car body color. This year there is an absence of striking color designs on most of the cars shown, although here and there a flashy body type is in evidence. The tendency seems to be toward more subdued colors and genuine luxuriousness of finish and equipment rather than freakish ideas designed to make a show of the occupants of the car. Conspicuousness in body colors has had its day if the showing in New York this year can be regarded as any criterion. Dark reds, blues, blacks and greens predominate and the finish in every case reflects the great care which has been exercised by every maker for harmony in body colors as well as for the ultra-refinement of finish.

Every style of body is to be seen. Touring cars, limousines, coupés, roadsters bring out the great strides which have been made in the body builders' art. Every conceivable feature for the comfort of the passengers has apparently been provided, and it is hard to see where further improvement is possible in body design. The fore-door type is universal, although many of the makers are exhibiting raceabouts of the characteristic openness. Among these may be mentioned the National, Moon, Mercer, Pathfinder, Stutz, Fiat, Abbott and a score of others.

In nearly every case body interiors correspond in color to the exteriors, although often in lighter shades. Black bodies have black leather finish within; dark blue types have corrresponding seating and side leather; brown exteriors carry brown

Upper—Diagonal view of the main floor at the Garden, looking toward the entrance
Lower—Another diagonal view at the Garden, looking away from the main entrance

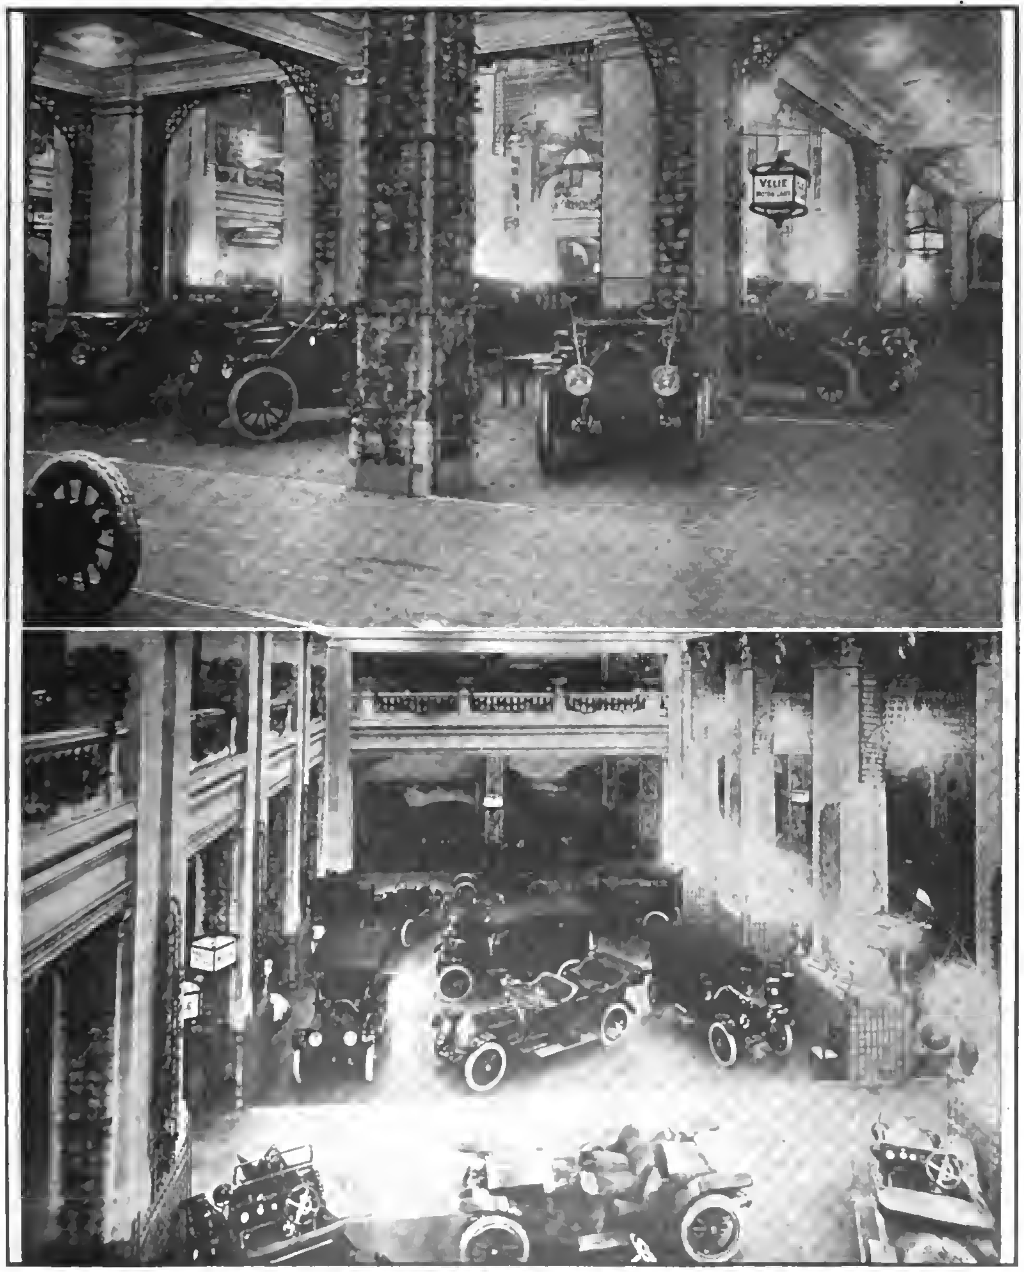
leather cushions and linings. Everywhere harmony is the keynote.

Looking at specific instances of ultra refinement in body design we may turn to the Locomobile limousine, which is a two-compartment type, the forward for the driver. This machine is of a dark maroon color and ranks in beauty favorably with any car yet brought out for the fastidious tastes of the automobile buyer. The interior of the passenger compartment of this beautiful car is transformed into a miniature drawing room. The walls and ceiling are lined with an old rose material into the pattern of which a flower design is woven. Miniature golden lamps are placed in the corners and every detail which will add to the comfort of the occupants has been included. Milady could scarcely wish for anything more in the way of refinement.

Striking in color is the Premier touring coupé, so called. This machine is finished in a bright green outside and shows a tendency to amalgamate foreign ideas of body construction with those of the American maker. This coupé is constructed somewhat on the landaulet idea, the top folding down, although the sides are on the coupé order. The top is also of the striking green which characterizes the body proper. Within, the finish is very elaborate, being in bird's-eye maple and light brown upholstery. Drive is on the left and control in the center. To add to the distinctive appearance of the whole, wire wheels are used, bringing out still more the dash of foreign style which has been added to the body design.

Stevens-Duryea models this year have a foreign air also as regards body design. The hood is of a new sloping type, rounded into the dash in a way which we are wont to credit to our contemporaries from England, France, Belgium, Germany or Italy. Fenders, too, on these cars are worthy of note in that they are very wide and substantially attached to the chassis. They are entirely welded together, no rivets being used. This construction but reflects the welding tendencies which are in evidence on many of the all-steel truck bodies now upon the market.

Very distinctive is the sedan limousine exhibited by Peerless. This machine has the rounded roof and the air of the royal equipage of earlier days. It is finished outside in yellow and black, while the interior leaves nothing to be desired in the way of luxuriousness. Packard, too, appears with the usual richness of body color and fineness of finish. Three Packards are shown, one an outside-drive coupé model finished in a dark blue. A noticeable feature of the body design of these cars this year is the absence of a door at the left of the driver's seat. This is true of the open models only, however, the closed cars retaining the door. The left front side of the bodies being thus closed, it is necessary for the driver to enter from the right front side. Reasons advanced for the design convey the idea that the left front door is of very little value inasmuch as the Packard control levers, which are placed at the left of the driver, make access from this side rather cramped and the other door is usually made use of anyway.

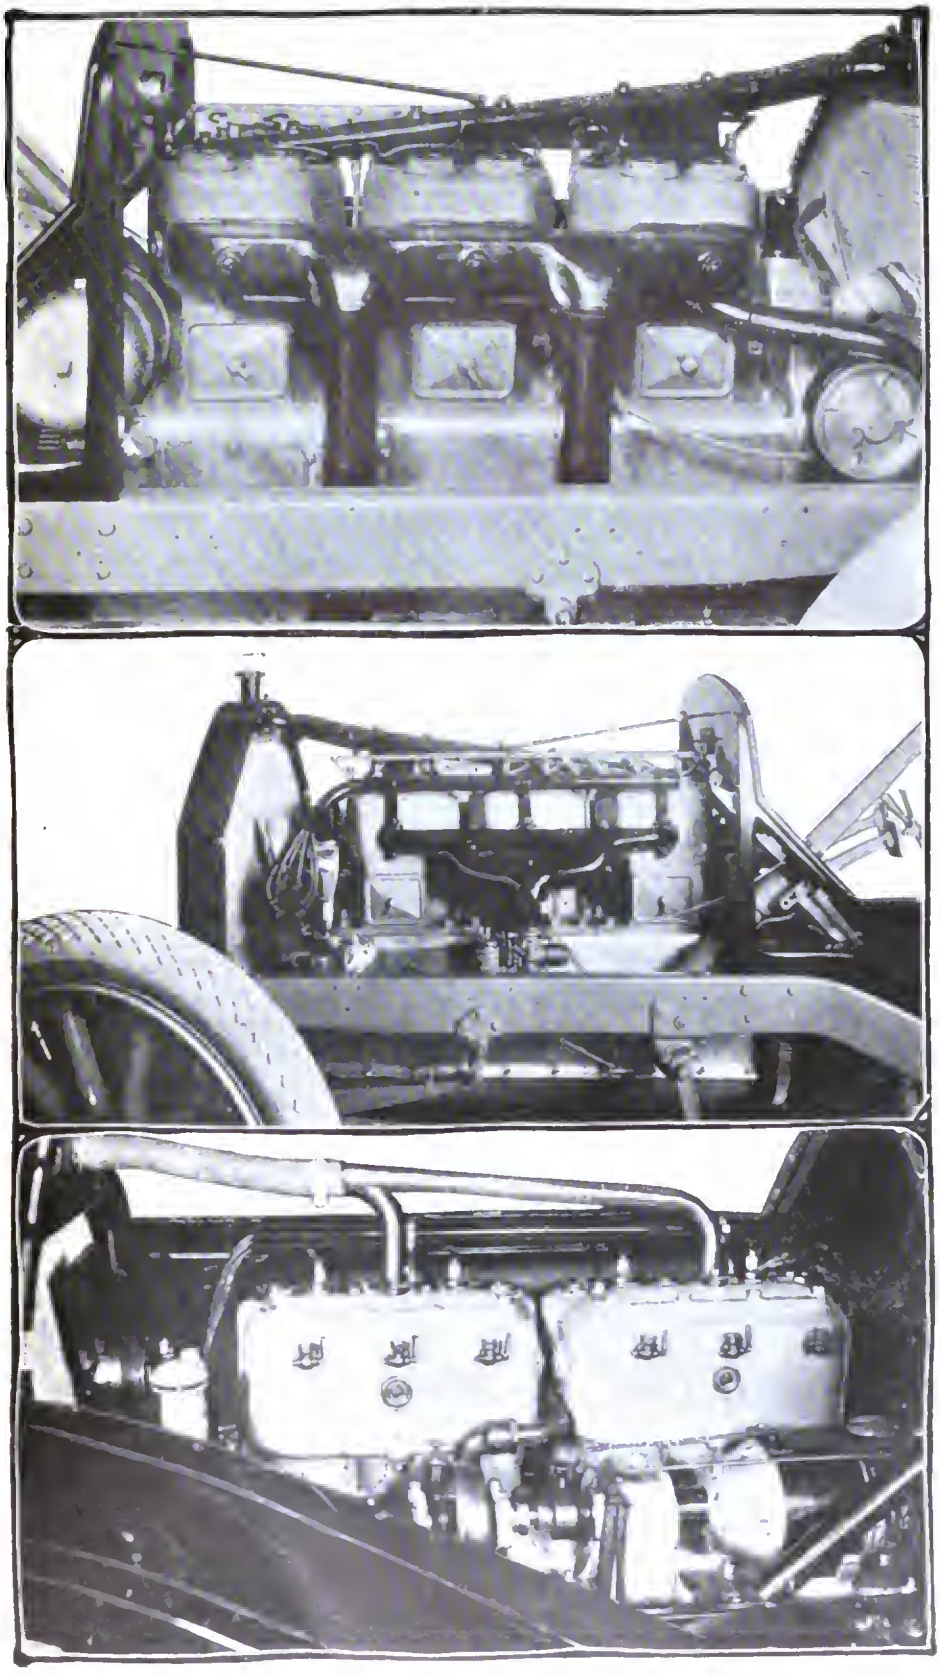


Two views of some of the exhibits on the main floor at the Grand Central Palace, showing the absence of crowding of the cars on display and giving an idea of the decorative scheme

Exhibitors are continually searching for novelties which will attract the spectators to their booths. An original idea has been used by the Packard company. In the glass of the headlights of one of the cars attractive scenes have been worked depicting Packard cars in the foreground. When the headlights are switched on, these scenes show to best advantage. Though a small thing, the idea is unique and attracts much attention.

Alco exhibits a single touring car model in its space at the lower end of the balcony at the Garden. It is placed on a raised platform at the back of the space and in front of it are spread rugs within the confines of the space, the boundaries of which are defined by brown rope draperies, thus further carrying out the color scheme. No chassis is shown.

A number of the makers are not showing a stripped chassis this year, among which are the Packard, Flanders, Oldsmobile and Maxwell, in addition



New Motors Seen at the Shows

Mitchell six (at top) is an entirely new design for the company and is a T-head engine with cylinders in pairs. It makes use of a transverse forward shaft for driving the magneto and water pump. The exhaust manifold has two branches which unite below the frame level. Both sets of valve mechanisms are inclosed and the Esterline cranking motor is mounted transversely at the right rear beneath the footboards, whereas the lighting generator is located under the driver's seat. The motor is clean cut. In fact, the entire chassis deserves mention on this score. The three-blade propeller type of fan is mounted in rear of the radiator. The motor shown at the bottom is that of the six-cylinder 60-horsepower Firestone-Columbus. It has a bore of 4.25 and a stroke of 5.25 inches. The North East electric system is used

to the Alco and several others. Nevertheless, chassis revealing mechanical constructions are in evidence at most of the spaces and it is to be noted that they are all in charge of better-informed attendants than was the case at shows of the past. Intelligent answers to questions has been the rule this year, for the maker realizes that the public is becoming motor-wise and must have facts. Thorough knowledge of the mechanical features of the car must now flow more freely than commendatory phrases regarding body advantages which are equally as evident to the layman as to the demonstrator.

Many new sixes are seen for the first time at the show. There is the new Garford, which has been heralded for some time, and it involves many features of foreign design, although produced by an American engineer—the creator of Overlands. The elements of torque tube construction, rear axle design and general chassis arrangements are more like those seen at the Importers' Salon at the Astor than typical American practice. The placing of a single headlight in the top of the radiator is a feature of the new Garford which cannot be credited to anyone save the designer of the car. This feature has already been discussed in a previous issue of THE AUTOMOBILE. Another new six is the Mitchell, which also involves a number of ideas obtained from the other side. The exhaust manifold on this car is perhaps the most radical feature for pleasure car design. There are two passages leading from the horizontal section of the manifold where it connects to the cylinders and running vertically downward into the main exhaust pipe which passes horizontally back to the muffler. Some such form of manifold construction is often utilized in racing car design, but it appears as rather a departure as applied to the passenger vehicle.

The Lozier light six also comes in for its share of attention inasmuch as it involves a number of features not formerly looked upon as characteristics of Lozier construction. The motor is an L-head type and carries a number of refinements, details of which would be irrelevant here. The reader is referred to last week's issue of THE AUTOMOBILE for a more comprehensive summary of the car's design. Although this new Lozier product is not in the small car class, it is designated as the light six to distinguish it from the larger model, which has heretofore been the exclusive production of the Lozier plant.

At the Palace the Chevrolet and Little sixes are on display for the first time, being products of subsidiaries of the recently-formed Republic Motors Company, a highly capitalized combine.

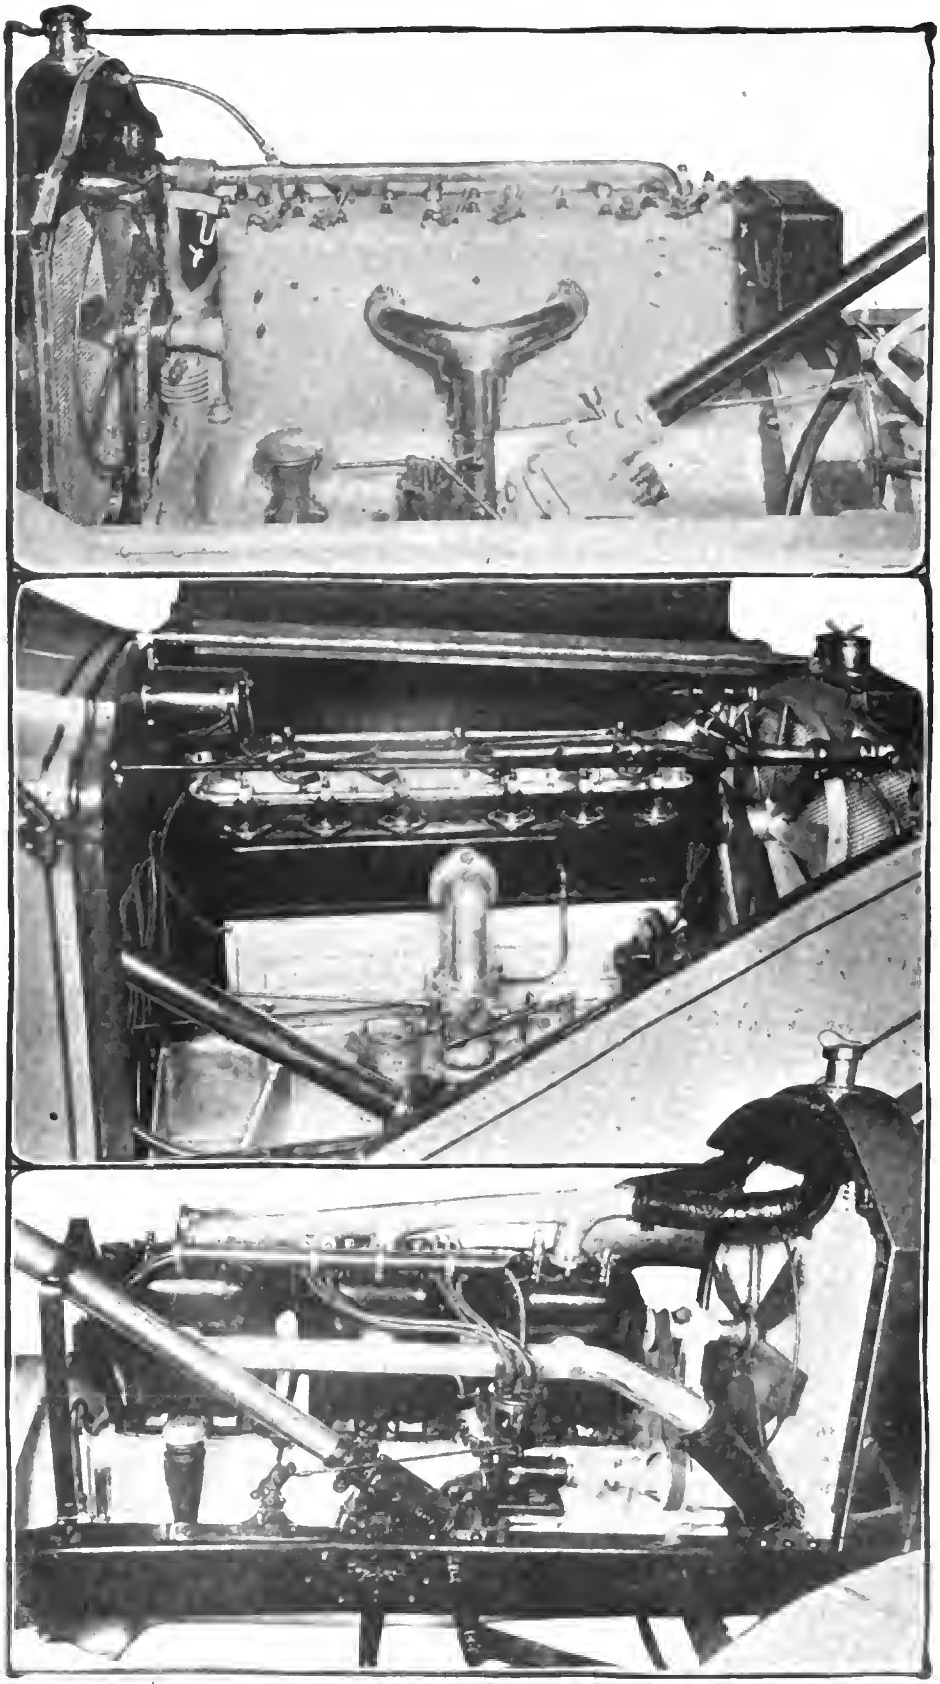
The Chevrolet involves many of the ideas of Louis Chevrolet, who has won distinction in the racing game. Naturally, a number of foreign ideas are incorporated. At the Palace also we find the new Studebaker line, which comprises two fours and a six of monobloc-cast motor construction. Here also is the new six-cylinder Stutz, product of Indianapolis. The little Herreshoff six-cylinder type is also to be seen, as well as a number of others.

Among the non-poppet valve type motor equipped cars, the Palace houses a rival of the Knight type, inasmuch as the Speedwell company exhibits its new car equipped with a Mead rotary-valve engine. This motor, although it has been exhibited at the shows before, is seen for the first time as a part of any particular make of car. The motor involves the use of two sleeves, one at either side of the cylinder heads of the monobloc casting, which sleeves are driven from the crankshaft by silent chains. When slots in these sleeves register with similar openings in the cylinder walls they permit the passage of gases either to or from cylinders as the case may be. Lubrication of these sleeves is accomplished through the placing of a small quantity of lubricating oil in the gasoline. As applied to the Speedwell car this motor appears at the show in connection with a touring car model.

The Knight-equipped cars this year have been augmented by the Edwards car, which makes its début at the Palace. The older adherents to this sleeve-valve motor, namely, the Stearns, Stoddard and Columbia concerns, are again on deck. The Stearns people have added the six-cylinder Knight-equipped car to their line, which shows no constructional features differing radically from those incorporated in this sleeve-valve motor as placed on cars of this make somewhat over a year ago when the company switched from the poppet-valve motor to the exclusive manufacture of the design of Charles W. Knight.

The Edwards-Knight, details of which appeared in a previous issue of THE AUTOMOBILE, is the only American car in this year's show to be equipped with a worm-driven rear axle. The worm is placed underneath the wheel, a position recommended by most engineers versed in this subject, although there are many who champion the use of the overhead worm.

Most notable of all the tendencies at the show this year is the almost universal adoption of some form of cranking system. A careful canvass of all the cars to be seen at the Garden shows that out of fifty models under investigation 70 per cent. are equipped with electric starting in some form or

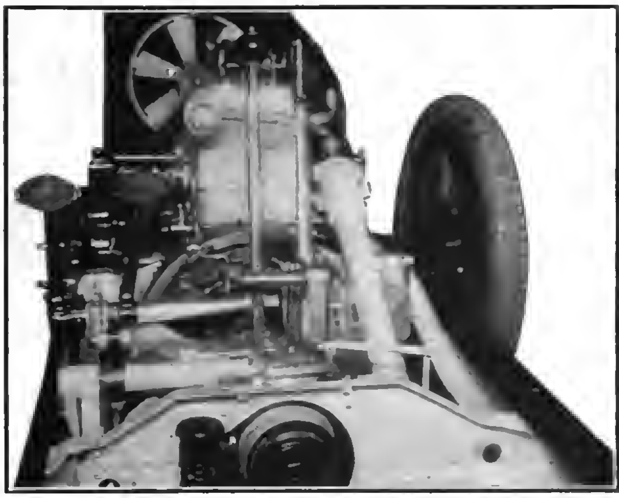


New Motors Seen at the Shows

Garford six (at top) with block casting having top portion of crankcase integral with cylinders and cylinder heads separate in the form of a large plate

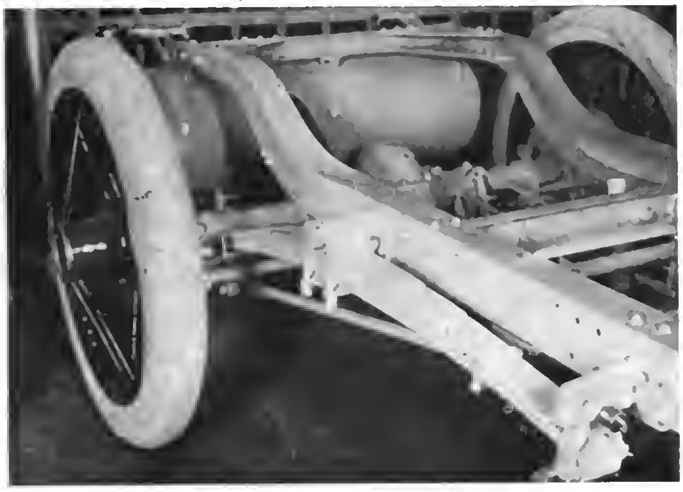
American six (center) is a T-type block design, the intake side of which is shown herewith. The cylinders measure 4.5 by 6 inches. The Electro motor-generator for cranking and lighting is used

Havers six (bottom) is not a new motor, but shows that type of design in which the cylinders are cast in pairs and have valves located on one side. The normal-sized water pipes for the thermo-syphon cooling are seen, as well as the Atwater-Kent ignition apparatus



Showing how propeller shaft is carried through large opening in center of cross piece of frame and how levers are mounted

One of the luxurious berline bodies is the Locomobile finished lavishly with gold trimmings



The Lanchester type of spring on the new Edwards-Knight chassis, showing how spring weight is carried on the car frame

other. Three of these cars carry acetylene starters, while four machines of this fifty are provided with an air starting system. Only six carry no provision for cranking the motor from the seat. In every case where electric starting is used, there is also electric lighting. Many of the electric starting systems with which our readers are already familiar are prominent in the chassis on display, although many new makes are also placed on well-known cars.

Considering the electric cranking situation, it is a noteworthy fact that the majority of the systems make use of three separate units to perform the various electrical functions, although there are a number of instances of the use of a single combined unit which takes care of the ignition, lighting and cranking. The principal illustration of this type of installation is the Delco system as utilized on the cars of the General Motors make. In all other cases under investigation either the magneto lighting generator and cranking motor are separately installed or two of these units are combined. Most of the two-unit applications combine the motor and generator into a single machine, while the magneto is entirely separate. The table, page 228, covering fifty machines taken at random, serves to bring out great diversity in the use of electric equipment on the cars of this year. The two-unit system, by which is meant the use of two electrical components to take care of the three functions, starting, lighting and ignition, usually appears in a combination of the motor and generator, while in a few cases notably the Westinghouse design, the electric generator and the magneto are combined in one unit while the cranking motor is made a separate unit

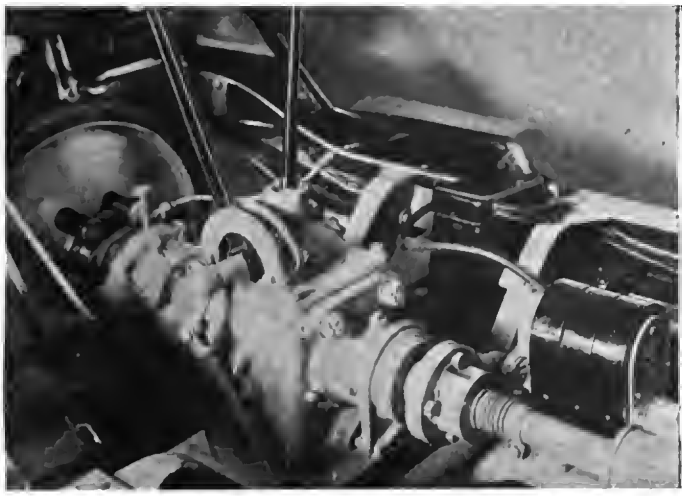
Segregating electric lighting from the other two electrical functions of cranking and ignition, it may be said that there are very few cases this year which do not incorporate electrical lighting as standard equipment, even though the starter may be of another type or one may not be used at all. The American buyer demands electrical lighting and it has become practically a universal feature, every concern fitting electric lights to at least one of its models. Of course, where no electric starting system is employed a storage battery charged from some external source is used for lighting.

The addition of these combined electric systems on such a large majority of the cars has meant the cluttering up of the power plants more or less, dependent upon the ingenuity of the engineers making the installation. Very little uniformity exists in the method of attachment of electric generators and cranking motors, although the application of this motor so that it will indirectly turn the crankshaft through gearing on the face of the flywheel predominates. Cranking motors the gears of which engage with these flywheel teeth are placed in innumerable positions, the applications beihg almost as varied in number as there are different makes of cars. One engineer places the electric motor forward of the flywheel, another back of it, another underneath, while a fourth mounts it above and crosswise, thus using bevel, spiral or worm gearing in connecting to the flywheel teeth. Several cases are to be noted in which the starting motor drives through silent chain or timing gears at the forward end of the engine.

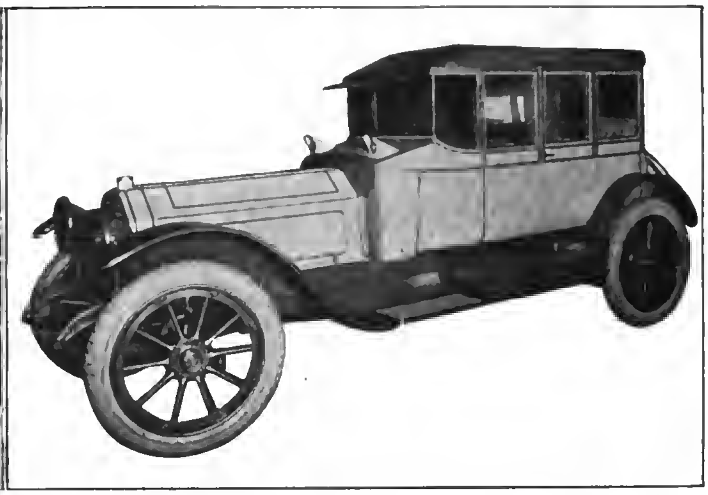
Then there are other installations which replace the flywheel of the engine by the rotating part of a motor generator. Notable examples of this is the design made by the United States Light & Heating Company and the installation mounted in the Rambler car. More detailed descriptions of starting systems appear elsewhere in THE AUTOMOBILE.

Air tire pumps appear on many of the cars exhibited, which is another feature tending toward convenience of the car operator. Makers installing air starting systems on their models, of course, have very little trouble in adding a connection which will allow the conveying of air to the tires. However, other makers who have electrical equipment have provided separate compressors or small tire pumps as an additional accessory. Considerable diversity of location of such pumps is in evidence.

Underslung springs are gaining in popularity. This construction must not be confused with the true underslung principle which involves the placing of the frame under the axles and suspending it by the springs, as in the American and Regal constructions. In underslinging the springs, the frame remains above the axles, while the springs are held up against the axle from underneath by means of spring bolts, as distinguished from the fastening of these springs above the axles as in average practice. This design must be credited to the Franklin company.



Compact gearbox on new Mitchell chassis and how gearshift and brake levers are mounted on it



New Peerless sedan body which is attracting general attention. The sides and front are all windows

which has been mounting its springs in this manner for some 5 years. The principle advantages of such construction are due to the permissible lower hanging of the frame without decreasing the road clearance. This allows the center of gravity of the entire construction to be lowered somewhat and tends to make the machine more stable, reducing the side sway and causing the car to cling to the road better. Examples of the underslinging of both front and rear springs are the Franklin, Mitchell, Abbott-Detroit and the Stevens-Duryea. The Oakland models are also provided with underslung springs, both front and rear, on the four-cylinder models and in the rear only on the six. The new Garford model also has underslung rear springs.

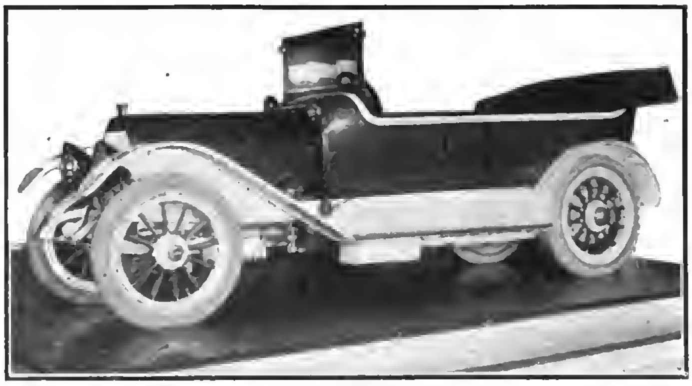
Departures from the conventional flat type of American radiators are also seen this year. Several have adopted V-shaped construction, notably the Oakland, Knox and Chevrolet. This type of radiator is not new in Europe, although just beginning to appear in this country. It was utilized last year in the Abbott Bulldog, which is seen again at the Palace. The Jackson cars are also equipped with a new radiator, which is rounded, the resultant effect of greater cooling surface being the same as that obtained through the use of the pointed or V-shaped type.

Taking up the question of drive and control, we find a number of concerns who have this year shifted to left drive, although the right-side driven car still appears to predominate. A list of the cars on the American market giving the drive is printed herewith and will serve to bring out the relative status of the various positions of the steering wheel. Only a few concerns make the drive optional with the purchaser of the car, these being the American, Knox, Moon, Pullman and several others. Among the makers at the show who are exhibiting entirely new models, the left drive is popular. Rather surprising was the appearance of all Packard models with left drive and control. When the little six Packard was brought out last fall with left drive and control it was the only machine of this make to be thus equipped, but now the Packard company announces complete change to this method of drive. On the other hand, the Peerless cars on which right or left drive was made optional last year have reverted to the use of right-hand drive exclusively.

The carrying of tires has been quite uniformly made a feature of the cars of the year in that special tire brackets are provided. In nearly every case the tires are carried at the rear on specially designed brackets, differing widely in construction. There are a few notable exceptions to this position of tire mounting, some concerns retaining the old placing on the running boards.

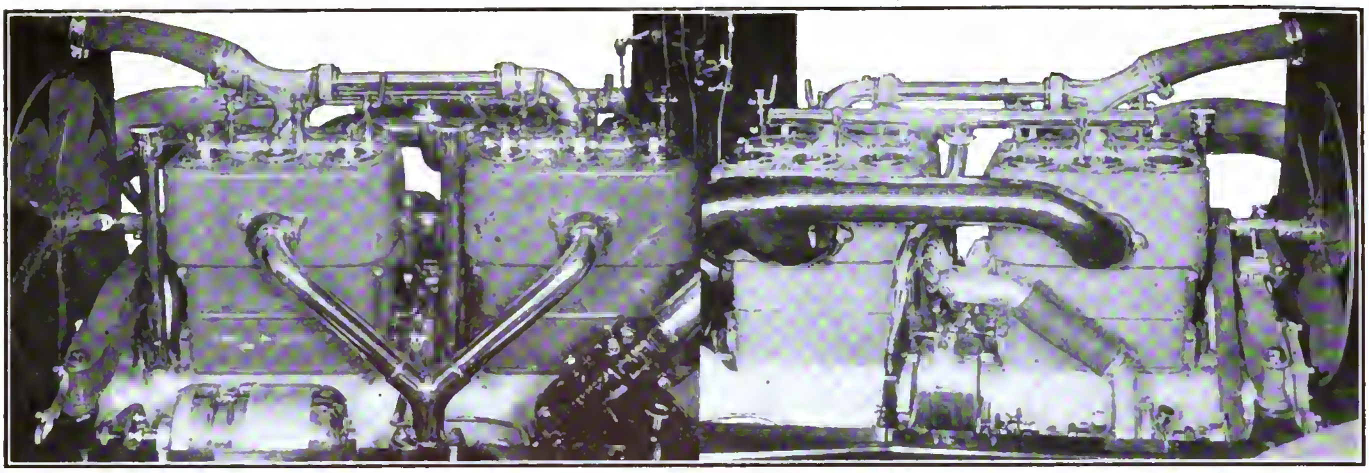
Wire wheels are gaining, if the number of cars so equipped at the show can be given as a criterion. One of the Stevens-Duryea cars is equipped with them, as well as one Premier model, a Haynes, a National, a Stutz and an Imperial. The price ranges

Three-quarter elliptic rear spring underslung on the new Garford six chassis



Owing to its small space the Alco showed but one model and mounted it on an elevated platform

from $125 to $200 extra for a set of five wheels, which are fitted with a demountable feature. Other companies which have adopted this wheel construction are the Keeton, Henderson, Pathfinder and Fiat. The increasing difficulty in the securing of first-class American hickory will no doubt in time work to the advantage of the wire wheel in this country. In the opinion of several exhibitors good hickory for spokes is rapidly becoming scarce and, consequently, too high in price. Hence the adoption of wire wheels is not far ahead.



Left—Intake side of the motor of the Little six, showing long Y-shaped intake manifold and mounting of electric starter, as well as substantial base of the steering column. Right—Chevrolet six motor, showing water connection between pump and cylinders

Transmission brakes have found very little favor in this country, although many of the European cars are provided with them, largely because their use is compulsory in several European countries, notably France. This year, however, we have one of our own cars equipped with a transmission brake. This is the National, which is equipped with a shoe bearing upon a collar on the driveshaft, and which is held out of engagement by a spring. This shoe is interconnected with the clutch pedal and when the latter is operated it is brought into play.

A growing tendency in motor design is that for the use of transverse shafts for driving magnetos and pumps, or pumps only. Such a construction allows the pump and magneto to be made very accessible from the sides of the motor, which constitutes one of the principal advantages. Among the makes of cars using cross-shafts are the Mitchell, Auburn, Marion, Pope-Hartford, Studebaker, Imperial, Fiat and Velie. The Stevens-Duryea cars have a cross-driven shaft for the pump only located at the front of the motor. The driving of such transverse shafts takes several forms, as does the location of the shaft with respect to the motor. In some cases the drive is through worm and gear, while in others spiral gears are used. Often the cross-shaft passes through the crankcase somewhere around the mid position of the motor. Examples of this are the Imperial and the Marion. In the new Mitchells and Studebakers the shaft is placed forward of the motor between it and the radiator.

Dash gasoline tanks are also with us in several machines, among them being the Henderson, Hupmobile, Cartercar and Paige. The principal advantages of this location are that it allows for easy filling of the tank as well as permitting the mounting of the carbureter higher. This latter feature makes the carbureter more accessible. The disadvantage has been advanced that such a location of the gasoline tank increases the danger of explosion or fire should anything ignite in the vicinity of the power plant.

Silence has been striven for more than ever this year, as evidenced by the designs which are on view at Garden and Palace. Noisy brake rods, fenders which would in time work loose, and squeaking springs are tabooed. On the Mitchell, for instance, brake ribbons of steel carried on rollers replace brake rods as a silence feature. This construction is similar to that used on the Panhard cars. More universal housing of valve springs is found, which may again be traced to desire for silence. Accessible grease cups are provided on nearly every one of the new models, so that the oiling of springs and other parts is made a simple matter. Even the operation of the spark and throttle levers is made quieter.

All down the line refinements in detail in the accessories have kept pace with the general refinements in motor car construction. Magnetos are being made more compactly, and are rendered waterproof in many cases. Rear axles are made of better mate-

Mead rotary valve motor. The side view shows the six ports or gas passages and there are six similar ones at the opposite side. The end view shows chain drive for the two rotary valves

rials and their gears are being cut with added accuracy and care in order to eliminate where physically possible chances of noise and failure. Steering gears have been refined and provided with more accessible points of lubrication and adjustment, so that the lay operator of the motor car will have no trouble keeping them in good condition. Lamps which are finished in any but nickel and black enamel are conspicuous by their absence, as were the former varieties several years ago. With the coming of electric lighting the compactness and general appearance and construction of lamps has been developed to the utmost.

The accessory exhibitors have duplicated their exhibits in some cases, that is, they have exhibits at both the Garden and the Palace. This is true of several of the tire people, one or two magneto makers and several in other lines.

Digest of the Leading Foreign Journals

Standards Accepted by French Truck Makers and Exceptional Designs Found Necessary for Special Work—Mechanical Means for Adapting the Diesel System to Small High-Speed Motors and Getting Benefits of Cheap Universal Fuels

TRUCKS at Paris Show.—While the economical advantage of motor trucks is identified in the United States mainly with the amount of wages to drivers, attendants and stablemen which is saved for a given amount of transportation work and, in the large cities, with the very considerable real estate values which are released for other uses through the abandonment of horse stables. the more direct reduction of operating and maintenance cost which may be effected through attention to construction details occupies the minds of French commentators on the situation much more prominently. The mechanical efficiency of the machine is considered the indispensable basis which must be worked out in minute details first of all. This view has almost excluded the electric storage battery vehicle from consideration but, on the other hand, has led to the adoption of steam vehicles for certain forms of work, to the use of trailers and tractors, to the development of four-wheel driving and steering and to the resumption of electric transmission, with a view to certain well-defined classes of work for which the mechanical efficiency cannot be attained by the usual construction. A review of the situation from the French viewpoint is summarized in the following extract of an article by Duanier.

The difficulties of the past, may now be considered to have been overcome, judging from the showing made at the recent Paris Salon. They consisted mainly in four factors: (1) A mistaken tendency to exaggerated tonnage, which proved incompatible with the actual condition of roads and bridges and also held vehicles too long waiting for full loads and made running uneconomical with small loads; (2) the distrust and ignorance of the public; (3) the mistaken idea of competing with railroads rather than supplementing and extending their work, and (4) the working out of technical questions relating to proportions in power, capacity, speed, strength of organs, spring suspensions. wheels and tires.

Though the whole range from 2 to 5 tons capacity is economically available, the standard motor truck is the 3½ ton vehicle, because this size permits the loading of an ordinary European railway freight car in three trips and yet, when operated with less than full load or empty, is fairly economical, having a considerable advantage at the latter point over the 5-ton truck.

For delivery vehicles intended to run at a speed as high as 20 miles per hour and shod with pneumatic or cushion tires, the scale of weights and power which seems to be established calls for chassis weighing from 2,000 to 3,500 pounds, bodies weighing from 1,760 to 2,200 pounds, loads from 1,760 to 3,500 pounds and motors ranging from 12 to 20 horsepowers.

The two makes of heavy steam trucks intended for loads from 4 to 8 tons, which are the Exshaw (formerly the Purrey) of Bordeaux, and the Fodens, are used chiefly for the transportation of coal, cement and paper.

The only electric storage battery vehicles are the forecarriage trucks made by the F. R. A. M. company and used mainly for pulling municipal sweepers. sprinklers and garbage carts.

For the moving of loads up to 15 tons over roads of any grade encountered in practice. the tractor construction which has been developed depends for sufficient road adhesion upon the use of four driving-wheels, and a trailing vehicle serves to distribute the heavy load over a sufficient road surface. The lead in this development was taken by the Panhard company which at the beginning of 1912 introduced, for military purposes, a gasoline motor truck with four-wheel drive and four-wheel steering and said to have been designed by the Austrian archduke Salvator, [described and illustrated in these columns; see THE AUTOMOBILE, March 21, 1912]. At the Paris Salon there were shown two equally interesting constructions of the same order, the Latil motor tractor, Fig. 1, and the Balachowsky & Caire tractor with electric transmission, Fig. 2.

The Latil tractor-truck has six forward and two reverse gear speeds obtained by a three-speed gear box worked in conjunction with a double bevel gear upon the differential. A separate lever controls the bevel gears, engaging one or the other. [This expedient is not new but is perhaps improved in details, as compared with the form in which it first appeared in 1902 or 1901. —ED.] The vehicle has three differentials from two of which the wheels are driven through transverse cardan shafts. The main differential is located upon the gear box, and from it the two other differentials upon the axles are driven by fore-and-aft shafts and worm gears. As the four wheels take equal parts in the steering, one differential might have sufficed, but the use of three of them renders the vehicle much easier to handle on rough lumpy ground where the four wheels cover irregular individual distances. Among the reference letters in Fig. 1, A denotes the 24 horsepower 4-cylinder motor, B the gear box, C the central differential, DD the differentials of the two driving axles, E the steering gear, FF the brakes of the four wheels, H the cone clutch, II the worm gear shafts, KK the transverse cardan shafts, L the steering shaft, MM casings for the wheel-gears, O hook for attaching trailer, PP steering levers, R the radiator with the centrifugal ventilation now universally used in French trucks.

In the Balachowsky tractor-truck with electric transmission no clutch, gears or chains are used. The energy developed in the 4-cylinder gasoline motor is delivered to a flywheel-dynamo and from the latter by wiring to four motors in the wheels. Self-excitation of the dynamo—whose armature constitutes the motor flywheel—is obtained by a special arrangement the nature of which is not published but which involves neither the use of a storage battery nor of an independent exciter. Self-regulation is attained by creating a zone of compensating currents in the center of the armature by the action of which currents the flow of electromotive force is diminished the moment the amperage increases, and obversely, so that the power absorbed by the dynamo remains constant when the speed of the motor remains constant. The whole gamut of power development and utilization is thus regulated operatively by the throttle alone. and the speed of the vehicle is independent of the motor speed, regulating itself as a function of the motor power and the resistance to traction. A switch is sufficient for starting the vehicle, forward or backward.

In the very simple chassis resulting from this construction, as shown in Fig. 2, *b* is the switch box, *c* the controller, *d* the dynamo-flywheel, d_1 the disconnector, d_2 the starter, *e* electric cables, *f* the hand-brake, f_1 brake levers, *k* trailer hooks, *m* the 4-cylinder gasoline motor, *r* the electric wheel-motors, *s* the muffler and *t* the brake drums.

These three types of four-wheel drive vehicles are intended largely for the work of transporting beets to the sugar refineries, for hauling stone and sand from quarries and pits, for hauling bricks and cement over the bad and steep roads usually found where these articles are made, for excavating and contracting work in general and, in the military field, for the engineering and artillery service, as for hauling siege ordnance and construction material for bridges. At recent maneuvers, one of them made it possible to transport a nine-inch siege mortar equipment, which was distributed in three trailer loads of four tons each, over ditches and ravines and to set it up in a plowed field.—From *Génie Civil,* December 21.

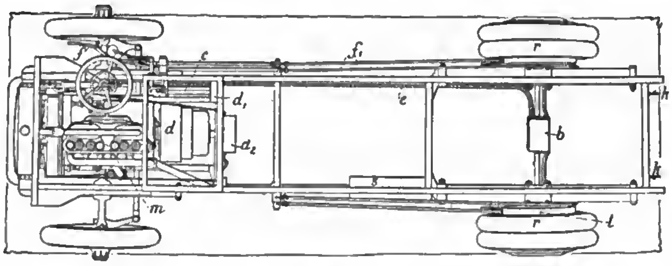

Fig. 2—Balachowsky & Caire tractor-truck with electric transmission and four-wheel drive

PROSPECTS for Diesel Motors for Automobile Use.—The rapid adoption of the automobile for serious transportation work, upon whose continuance prosperity in peace and success in war may at any time come to depend, looks more and more like a leap in the dark, so long as nothing decisive has been done to make sure of the fuel supply. To all Europeans this shadow upon the development looks especially gloomy, as the doubling of the price demanded for gasoline derived from American petroleum has made it very clear that they are at the mercy not only of the limitations of the natural supply but also of the good will of a foreign nation and of speculators in that nation as well as in their own. The only other fuel of which it is known that it can be used in the existing automobile motors is benzol, which is a by product of cokeries and gas works and which now, since the demand for it has set in, threatens to rival gasoline in price. The mere chance that petroleum wells may be located in Africa and China from which a good fuel may be obtained gives only scant comfort. Much more promising is the chance of adapting the automobile motor to fuels which may be produced in any quantity in any country.

The Diesel motor is such an engine, for while it is at present operated mostly with the heavy residue of petroleum as a fuel because the supply thereof is still cheap and abundant—though rising in price—it is adapted for burning oil of coal tar with equal success and also any animal or vegetable oil. At present prices for heavy oil in Germany it can be operated at a fuel cost of 3 pfennig per horsepower-hour and at one-half of this cost where tar oil is a local product, while the same amount of work performed by an automobile motor with gasoline costing 45 pfennig per liter (about 40 cents per gallon) comes to 18 pfennig, being 6 times higher, and with benzol at the present price of 30 pfennig per liter, comes to 12 pfennig, or 4 times higher. Furthermore, the Diesel motor loses little in economy when adjusted down to half power or less, while the automobile motor loses heavily in fuel efficiency under the throttle, under which condition it is mostly used.

But the Diesel motor is very heavy and very costly, and it has never been operated successfully at much more than 550 revolutions per minute. These features completely unfit it for the automobile. The question is whether they can be circumvented or not. Diesel himself has said that he is still working upon its adaptation to automobile work. An engineer, Otto Malms of Mannheim, discusses in a recently published article the possibilities for overcoming the great technical difficulties which stand in the way. These arise from (1) the very high compression and piston pressures which render a very substantial construction necessary, from (2) the need of measuring accurately very small amounts of fuel in a liquid state and carrying it to the injector valves in the same state with a frequency at least three times greater than that required in any regular stationary or marine Diesel motor, and (3) from the same necessity for combining accuracy, high speed and infinitesimal quantity in the injection and atomizing of the fuel.

ONE PROBLEM ALREADY HALF SOLVED

The question of strength and weight does not seem half as formidable as it appeared a few years ago, as some of the latter-day automobile motors work with pressures of 25 to 30 atmospheres and the pressure in a small-sized Diesel motor does not usually exceed 35 atmospheres. Moreover, aviation motors are produced which sustain similar pressures at a weight of only 2 to 3 kilograms per horsepower, or less than one-half of what the advanced automobile motors weigh. It must therefore be assumed that the quality of materials and the art of incorporating them in the design of motors have already reached a point at which 35 atmospheres can be taken care of without notably increasing the present weight of automobile motors, their pistons, connecting-rods, crankshafts and camshaft mechanism. To be sure, the compressor plant for the injection of the fuel means an additional weight, but on the other hand the weight of the magneto and the carbureter is saved.

THE PRINCIPAL PRACTICAL DIFFICULTY

The operation of a Diesel motor depends absolutely upon having a strictly measured amount of liquid fuel dosed into the injector nozzle of each cylinder preceding each combustion stroke and to be deposited there in a liquid state ready to be blown into the cylinder by the use of compressed air at the beginning of the stroke and during a portion of its duration. These small fuel doses must be reduced exactly in proportion if the load of the motor is reduced. When the motor runs idle they should be about one-fourth as large as at full load.

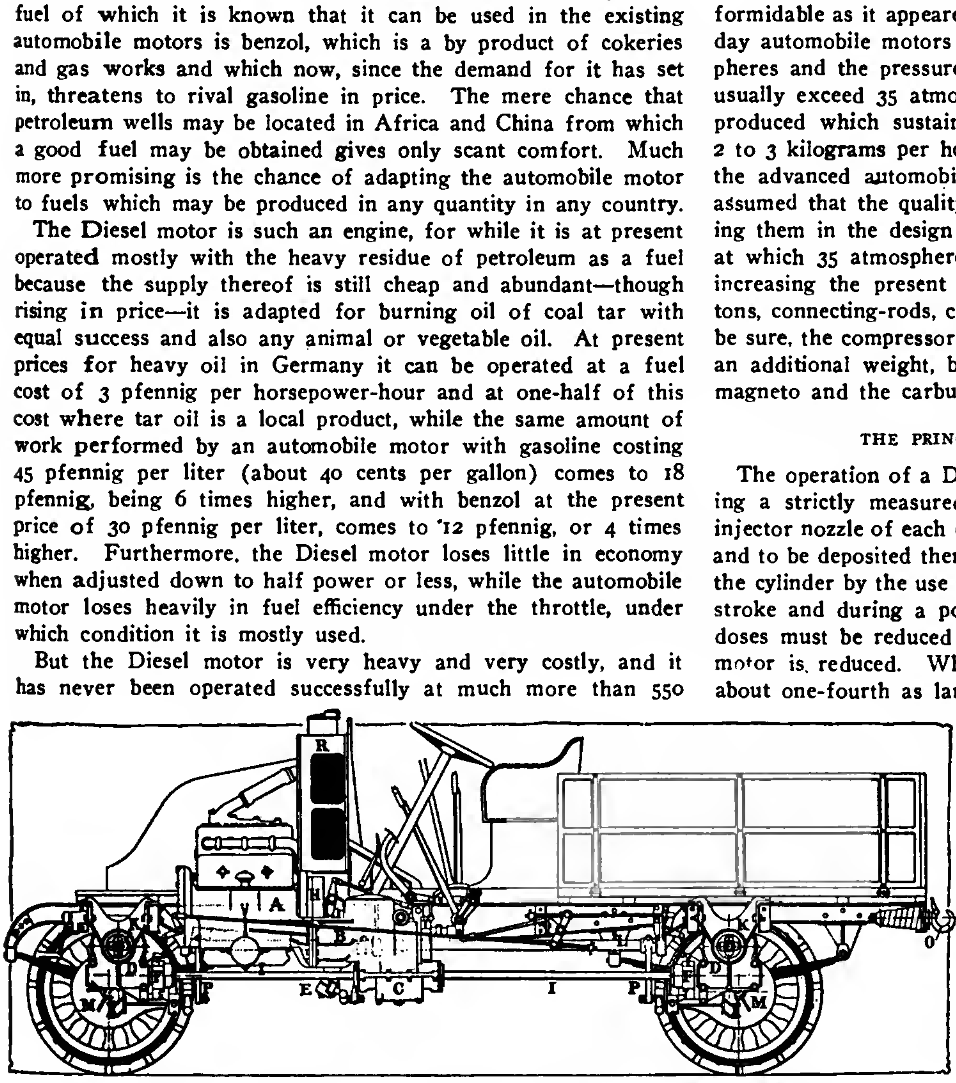

Fig. 1—The Latil tractor-truck with four-wheel driving and steering

The quantities to be measured in this manner in an automobile motor of fairly high speed would be exceedingly small and would have to be delivered up to 700 to 750 times per minute for each cylinder in the case of a four-cycle motor and twice as rapidly if the two-cycle system were adopted, as it now usually is in Diesel motors for use in boats and ships. A simple calculation, based on burning 10 liters of fuel per hour in a 40 horsepower motor of 4 inch bore and 5¼ inch stroke, shows that the dose to be delivered at each action would involve only a stroke of 3.1 millimeters of a pump piston 5 millimeters in diameter at full power of the motor; and with the motor running idle the pump stroke could be only 0.8 millimeter long. Such miniature work and workmanship are scarcely practicable. In ordinary Diesel motors of much larger size the pumps are made to handle a 3 times larger quantity of fuel at each stroke than that momentarily required and a provision is made for returning each time from 2/3 to 11/12 thereof to the suction pipe, but even with this system of differential pumping the quantities to be handled in an automobile motor would be far too small. In other words the fuel pumps of Diesel motors have to be redesigned for automobile purposes.

A number of methods may be imagined and have been more or less seriously proposed or even tried, but in each of them some difficulty crops out upon closer investigation. Fig. 3 indicates, for example, a method which seems very plausible, and the feature of the open nozzle which is incorporated in it and which also is used in most of the modern stationary Diesel motors seems in fact indispensable for any high-speed automobile Diesel motor, as it admits of introducing the fuel against low pressure rather than against the 50 to 60 atmospheres of the air compressor and also renders it possible to use the pressure air at a higher temperature, so that special cooling of it becomes unnecessary.

According to Fig. 3 the fuel is kept in a tank under constant but low pressure and is admitted through the needle valve *n* into the nozzle *d* during the suction stroke of the motor when the resistance is small. The needle valve is controlled by the cam *o*, and by the use of a slidable oblique cam the time during which the valve is kept open—the stroke of its needle—may be adjusted to correspond with variations of the motor load. Certain measured amounts of fuel may thus be introduced if only the pressure in the fuel tank is kept constant, and this may easily be done by means of an air pump with a certain amount of dead space.

The fatal objection to the arrangement is that, when the amount of fuel introduced in the open nozzle depends upon the time during which the valve is open, it also thereby depends upon the speed of the motor, while the size of each dose should depend upon the load of the motor.

ONE SOLUTION OF THE FUEL FEED PROBLEM

Figs. 4 and 5 show sketches of an arrangement promising results more in accordance with the requirements. It is meant to sustain a pressure upon the fuel supply proportionate to the power requirement at any moment. The arrangement is not proposed as final but as one showing that the problem can be practically solved. It is assumed that piston pumps should be used, since rotary pumps are less positive and more efficient at high than at low speed, while the requirement is exact measurement independently of the speed. It is also assumed that these piston pumps should be of such a size that they can be practically manufactured and operated. To this end each pump stroke is arranged to furnish fuel for more than one combustion, the pumps being geared down to run much slower than the motor. To get a perfectly constant stream of fuel, two pump pistons may be driven from two cams n_1 and n_2 so shaped that the two pressure strokes blend into a perfect continuity, and the distribution to the four nozzles of the four motor cylinders can be made on the plan shown in Fig. 3, using one positively operated admission valve for each cylinder nozzle, and these valves may, under the varying fuel pressure, always be worked with the same stroke of the needle valve and the same duration of the fuel admission.

In order to reduce the fuel admission when this is required, the cams may be made laterally displaceable and oblique of conformation. It may be a mechanical task to shape such cams properly in the first place, considering that at any adjustment they should produce a perfectly measured pressure-flow of the fuel [and it seems that it would be necessary to provide a spring-resistance to this fuel pressure, and possibly a safety valve, in the fuel receptacle from which it is fed to the valves and nozzles.—ED.] But, once made and tested out, it could be easily reproduced in a milling machine.

Fig. 5 illustrates how a pair of cams cut on curves of the Archimedean spiral may be designed so as to produce for any one-sixteenth of a revolution of the camshaft the same amount of advancement in the pressure stroke of one or the other of the two pistons. The actions of the two pistons can also be made to overlap.

With this style of fuel feed, the same size of pump can be made for different sizes of motors, the pumps being driven with a greater speed reduction the smaller the motor is.

How the difficulties relating to the injection of the fuel into the cylinders by means of compressed air may be overcome forms the subject of another chapter.—From *Allgemeine Automobil Zeitung*, December 18 and 20.

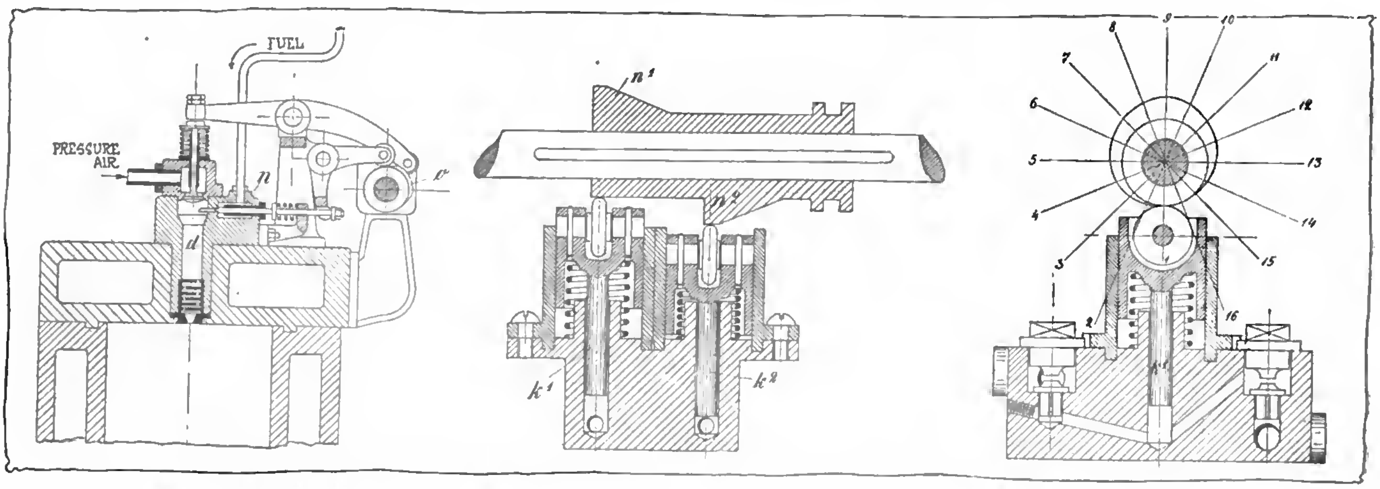
—

"Solid Air" is the taking name of a new tire-filling substance which according to the reports from the Paris Salon can be injected in tires at different tensions, to correspond with the weight and normal load of the vehicle as well as the size of the tire casing. Injected in a liquid state it becomes plastic in a few hours and generates occluded gas in millions of cells. It is said to be compressible and inextensible, while rubber is incompressible but extensible.—From *L'Auto*, December 21.

—

Neat Metal Foot Boards are taking the place of wooden ones in some English cars. Nazarro, in his Italian car, shows an inclined metal dashboard of rare elegance.

Inside Twin Tire.—At the stand of J. Faure at the Paris Salon means were shown for adding a twin tire on the inner side of a wheel. A better mechanical makeshift—where there is room for it—than adding it on the outer side!



Figs. 4, 5 and 6—Details in the reconstruction of the Diesel fuel feed system for use in automobile motors

Stroke vs Bore

America . . . 1.22
France 1.65
Gt. Britain . . 1.43

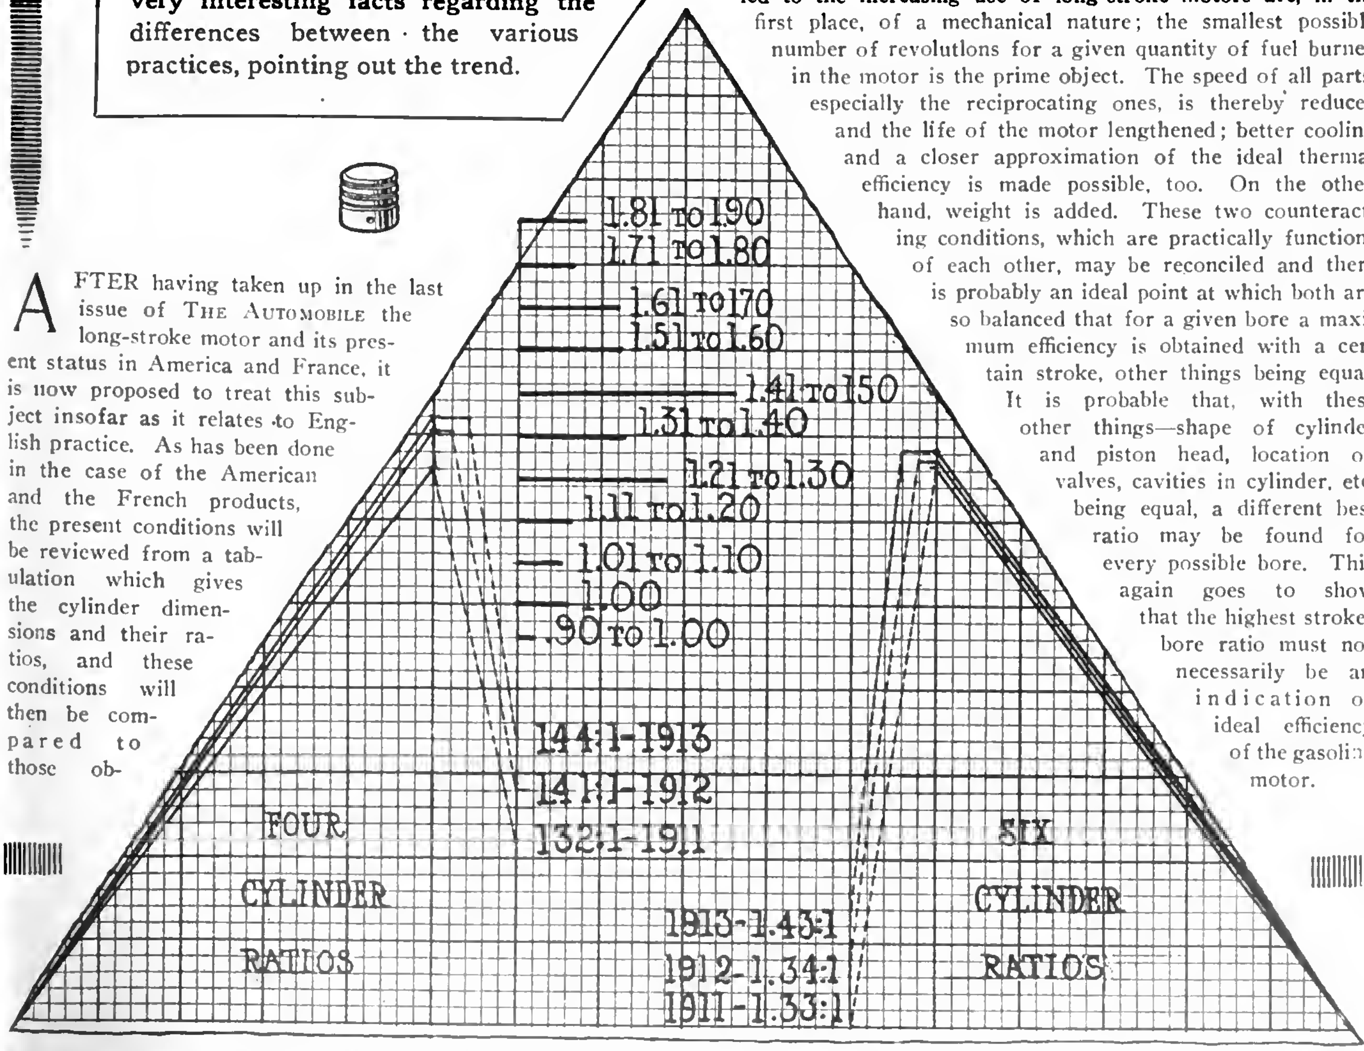
Installment II

¶ The English motors, which range in average stroke-bore ratio between the American and French averages, are reviewed in this article and the British situation is compared to those obtaining in the United States and on the continent.

¶ This comparison brings out some very interesting facts regarding the differences between the various practices, pointing out the trend.

AFTER having taken up in the last issue of THE AUTOMOBILE the long-stroke motor and its present status in America and France, it is now proposed to treat this subject insofar as it relates to English practice. As has been done in the case of the American and the French products, the present conditions will be reviewed from a tabulation which gives the cylinder dimensions and their ratios, and these conditions will then be compared to those obtaining in the 2 preceding years. This process shows that during each of the past 3 years England stood midway between France and America in respect of the average stroke-bore ratio, and that this ratio has risen constantly during this time and at a rate practically parallel to that of the increase in French and American motors.

Remembering that this article takes into consideration only the stroke-bore ratio in general, as well as particular and striking instances, the reader should not attempt to draw too bold conclusions from the subject of the article. The subject of horsepower, which is more closely related to piston displacement than to anything else, is beyond the scope of this review, and there is every reason for this being so. The considerations which have led to the increasing use of long-stroke motors are, in the first place, of a mechanical nature; the smallest possible number of revolutions for a given quantity of fuel burned in the motor is the prime object. The speed of all parts, especially the reciprocating ones, is thereby reduced and the life of the motor lengthened; better cooling and a closer approximation of the ideal thermal efficiency is made possible, too. On the other hand, weight is added. These two counteracting conditions, which are practically functions of each other, may be reconciled and there is probably an ideal point at which both are so balanced that for a given bore a maximum efficiency is obtained with a certain stroke, other things being equal. It is probable that, with these other things—shape of cylinder and piston head, location of valves, cavities in cylinder, etc. being equal, a different best ratio may be found for every possible bore. This again goes to show that the highest stroke-bore ratio must not necessarily be an indication of ideal efficiency of the gasoline motor.



Stroke-bore ratios of English motors for the past 3 years, showing its constant increase, and in center classification of motors by ratios

The 1913 list of English motors shows a total of 114 motors of which ninety-two are fours and twenty-two sixes, corresponding to percentages of 80.5 and 19.5. This compares with 1912 as follows: In that year there were eighty-six fours and twenty-three sixes or 78.9 and 21.1 per cent. respectively, making a total of 109 power plants. In 1911 there were eighty-seven motors of which seventy-one were fours and sixteen sixes, the percentages being 81.6 and 18.4 respectively. The ratios of fours and sixes during the past 3 years were as follows:

	1911	1912	1913
Four cylinder	1.32	1.41	1.44
Six cylinder	1.33	1.34	1.37

The following tabulation shows the distribution of English 1913, four and six-cylinder motors classified by their stroke bore ratios:

Ratio	Fours	Sixes	Total
1.01 to 1.10	4	1	5
1.11 to 1.20	6	..	6
1.21 to 1.30	15	3	18
1.31 to 1.40	11	2	13
1.41 to 1.50	17	9	26
1.51 to 1.60	11	1	12
1.61 to 1.70	11	1	12
1.71 to 1.80	5	1	6
1.81 to 1.90	7	..	7
Square motors	3	3	6
Short stroke	2	..	2
Totals	92	22	114

The greatest number of motors have a ratio between 1.41 and 1.50 and the average would be about 1.45 were it not for the fact that the bore-stroke ratios below 1.40:1 outnumber by far the motors having a greater ratio than 1.50:1.

As the accompanying tabulation of the bore and stroke ratios for the past 3 years shows, the leaders for 1913 are found among the four-cylinder designs, the greatest ratio being 1.88:1. This is the ratio of the Belsize, of the smallest bore. The same ratio is used in the larger Calthorpe, the little Humber and the larger Vulcan model. Then follows one each of the Star and Sunbeam cars with a ratio of 1.87:1, the next highest in the line being the second Calthorpe, 1.81:1. Without quoting any further high ratios which may be seen upon examining the tabulation, attention is called to the peculiar manner in which the great majority of British cars range within narrow limits of ratio, thereby differing considerably from American practice, in which a relatively high percentage of motors is distributed through a ratio range from 1.00 to 1.50:1.

Among the sixes the larger Daimler car leads with a ratio of 1.75:1 and its closest follower is the Armstrong, 1.67:1, next to which ranks the small Napier, 1.55:1. While there are no short stroke designs among the 1913 sixes, three square motors or 13.7 per cent. of the total of twenty-two motors, show that the conservative idea of a relatively short stroke is still alive.

Twenty-one out of the ninety-two four-cylinder motors have greater ratios than last year's product of the same make and twelve motors have smaller ratios, corresponding to 23 and 13 per cent. of the total, respectively. Among the sixes there are four increases of ratio and one case of decrease, or 18 and 4.5 per cent. respectively.

The greatest gain in ratio among the four-cylinder designs is that of the Star which has a ratio of 1.67:1, this being 25 per cent. in excess of last year. Next is the Humber, fourth of its name in the tabulation, the ratio of which has been increased 23 per cent. since 1912. The third Argyll has a ratio 18 per cent. larger than last year. Britton and B. S. A. have each increased their ratios by 15 per cent., the third Armstrong by 12 per cent., the Enfield has gained 13 per cent. and there are a number of designs which have been enlarged in their ratios by less than 10 per cent. The largest decrease is that of the Argyll appearing as the second of its name in the tabulation, namely, 32 per cent. The Austin, with a decrease of 16 per cent. is second, the Clement third with 11 per cent., and the Straker fourth with 6.5 per cent.

In the six-cylinder class the larger Daimler leads with a ratio increase of 46 per cent. against last year. The other increases of ratio are comparatively insignificant, the Armstrong being second with a gain of 11.4 per cent. and the Vauxhall third, with 4.5 per cent. The Sunbeam is the only case of lessened ratio, this year's being 10 per cent. smaller than that of 1912.

If we consider the meaning of these

figures we find that they indicate a slackening of the long-stroke tendency in English practice. This is true, despite the fact that the average stroke-bore ratio has increased 3 per cent. for 1912 and 4.4 per cent. for 1913, and that the rate of increase of long-stroke motors is seemingly the same, or approximately the same, as in America. The fact, however, that among thirty-nine British motors which have altered their stroke-bore ratio there are twenty-five, or 64 per cent., in which it has been increased, and fourteen, or 36 per cent., in which it has been decreased, indicates that English designers are traveling a different road from their American confreres. Of course, there are many long-stroke motors which have been continued without change from 1912 to 1913 and these serve to maintain the average of 1.43:1 for this year; but the fact that only twice as many makers have increased the ratio of their product than have decreased it is a strong indication of a change of mind on the part of English designers and engineers. This is so much more remarkable as French practice does not show any such change of tendency, but the long-stroke idea continues in favor.

It would be most interesting to study the circumstances which have brought about this change of pace on the part of the British manufacturer, but unfortunately this material is in the hands of the individual makers and is not accessible to outsiders. It may be expected, however, that the year 1913 will clear the situation and show whether this reversal of stroke-bore ratio development has been accidental or not, whether it was a step in a new direction or merely an attempt to go back to an engineering fashion of the past.

Nevertheless, an exact study of the tabulation of French motor dimensions and ratios as shown on page 78 of THE AUTOMOBILE for January 9 brings out the fact that England does not stand entirely alone in the retardation of the movement in the long-stroke direction.

The French motors which have what might be termed a long stroke, even in French eyes, that is 2.00:1 or more, have in most cases had this ratio during 1912, there being practically no creations of 1913 having such a high ratio. The tabulation mentioned above shows that 1913 has produced a very small number of new motors, among which there are only seven of a ratio of 2.00:1 or more. Still, the number of French motors having such ratios is more than twenty, so that hardly one-third of these long-stroke designs are products of the 1913 season.

American practice, on the other hand, does not indicate in any manner that it will follow the British designer on the path which he seems to have chosen. As has been shown in the first installment of this article, the American trend is very strong toward longer stroke and it might be reasoned that the optimum lies somewhere between the present ratios of England and France or is perhaps identical with the latter. This would explain the slower movement of English and French motor practice toward a high stroke-bore ratio. It is only reasonable to expect that when the advantages of long-stroke design are developed beyond a certain point they begin to make themselves felt as disadvantages or at least are not desirable for ordinary road work. The lengthening of the stroke with the continued use of a given bore naturally calls for either a higher center of gravity, or a wider crankcase and an increase of weight on the part of the latter or else an increase of the reciprocating mass in the motor. This increase of weight, if continued far enough, will offset the advantages derived from a long stroke, namely the lower angular velocity for a given piston speed. If this were not the case it would be very strange that so many French manufacturers who used a stroke-bore ratio of, say 2.04 in 1912 did not further increase it for 1913, although the Sizaire-Naudin car with its 2.48:1 ratio has had splendid success during the past 2 years, especially in racing practice. Furthermore, the fact that the ratio of the latter has been continued without change appears to be a silent way of admitting that the designer of this product has reached what he considers the limit in the long-stroke line.

Communications from The Manufacturer

J. A. Cleveland Finds Electric Truck About 50 Per Cent. Cheaper Than Horse and Wagon

THE evolution and rapid development of the automobile has been an important factor in facilitating the transaction of business and the transportation of merchandise within cities. The automobile has almost entirely supplanted the horse for ordinary pleasure and business service, and the automobile truck has begun to displace the dray and cart horse for commercial purposes.

As a result of this development in the automobile industry a great opportunity is presented to the central stations of the country for obtaining an important and valuable adjunct to their load, and from which they can derive an extremely profitable class of business. The electric vehicle is generally used during the day and evening and can be most conveniently charged during the night. This introduces a class of business which will use electrical energy during the very hours that the load upon the station is light. As a result, this business will tend to improve the daily load factor of the central station, and, furthermore, as the pleasure vehicles are used more in summer than in winter the business will improve the yearly load factor as well. The current used in charging is an off-peak load. coming on at the time of the lowest point in the load curve and requiring no increase in station investment. The load is one in which there are no fluctuations. As a current consumer the electric vehicle is decidedly attractive, the consumption varying as it does from 1,500 to 12.000 kilowatt-hours per car per annum.

The electrification of our city street railways marked an important step in the development of travel within cities and supplied the central station with an important consumer. The electrification of our city merchandise transportation system now presents another consumer of great possibilities. Commercial conditions are requiring a more rapid transfer of merchandise and in our larger cities the congestion of merchandise is becoming a serious problem. The electrical system applied to trucks offers advantages over the gasoline system in many respects. Electric motors are more simple in construction, and more durable and efficient in operation than the gasoline engine. Improvements in batteries during the past few years have greatly increased their efficiency. The speed of the electric truck is limited by the size of the motor and the number of cells in the batteries, and a check is thereby secured upon reckless driving which would result in disastrous accidents. Furthermore, the slower and more uniform speed prevents severe jolting of all parts of the machine and results in a lower maintenance cost.

Work for Central Stations

Opportunities are now offered to the central stations to help foster and develop the use of the electric vehicle and thereby secure for themselves an increased revenue. Inasmuch as this class of business is a non-peak load, special low rates are generally given. This increases the sales, but it has also been found to induce carelessness on the part of the consumer. This carelessness and excessive use of current results in frequent overcharging and ruining of the batteries. This practice will tend to cause dissatisfaction and will result in retarding the increase in use of electric vehicles. It is therefore evident that the central station must lend its assistance in educating the people regarding the proper methods to be used in charging the batteries, as well as handling the machine, in so far, as the electrical equipment is concerned. A number of central stations in the larger cities employ a man especially for this purpose, and his services are available to the public without any charge. This is, of course, impracticable except in large cities, but every company usually has some electrical employee possessing more or less knowledge in regard to the operation and care of electric vehicles and he could with some assistance and help increase his knowledge so that he would be of assistance to the public in this connection. The successful introduction and wide use of these vehicles depends upon the education of the public in their proper application and care. An educational campaign and some expert assistance is needed so that the vehicles used may be adopted to the purpose and service demanded of them. This business demands the same care and attention as is given to the prospective power user in recommending to him the proper type and size of motor adapted to his needs, and to the merchant in explaining to him the best system of illumination to adopt.

The aim of the central station being to help increase and develop this class of business, it naturally follows that the company itself should be among the first to utilize the service. Instead of using line wagons, repair wagons and meter wagons, it should use electric trucks for these purposes. In addition to thus daily advertising this service, the company itself can increase the efficiency of its own organization.

Actual Daily Truck Record Kept

In Saginaw the companies now have two electric trucks in daily use, one a 1,000-pound gas company truck as a meter and service truck, and the other, a 2.000-pound truck, used by the power company as a service and line repair truck. These trucks were purchased during the past summer from the Argo Electric Vehicle Company, of Saginaw, and have given most satisfactory service under all conditions. The smaller truck was put in operation June 12, 1911, and was used by the power company in connection with extensive pole and line work that was being done. Instead of purchasing an additional team and wagon, which would have been needed at this time, it was thought best to try an electric truck. It was found, however, that a 1,000-pound truck was too light for the heavy loads of wire and line material and later on a 2,000-pound truck was ordered and placed in operation in October. The smaller truck was then transferred to the gas company to be used as a meter and service truck, taking the place of two horses and wagons.

From the day the first truck was put in operation, a record was kept showing the number of miles traveled each day, and the actual number of hours and minutes each day that was spent in traveling as distinguished from the time that the truck was standing still while the men were at work at any one location, and the number of men each day that were employed upon the work.

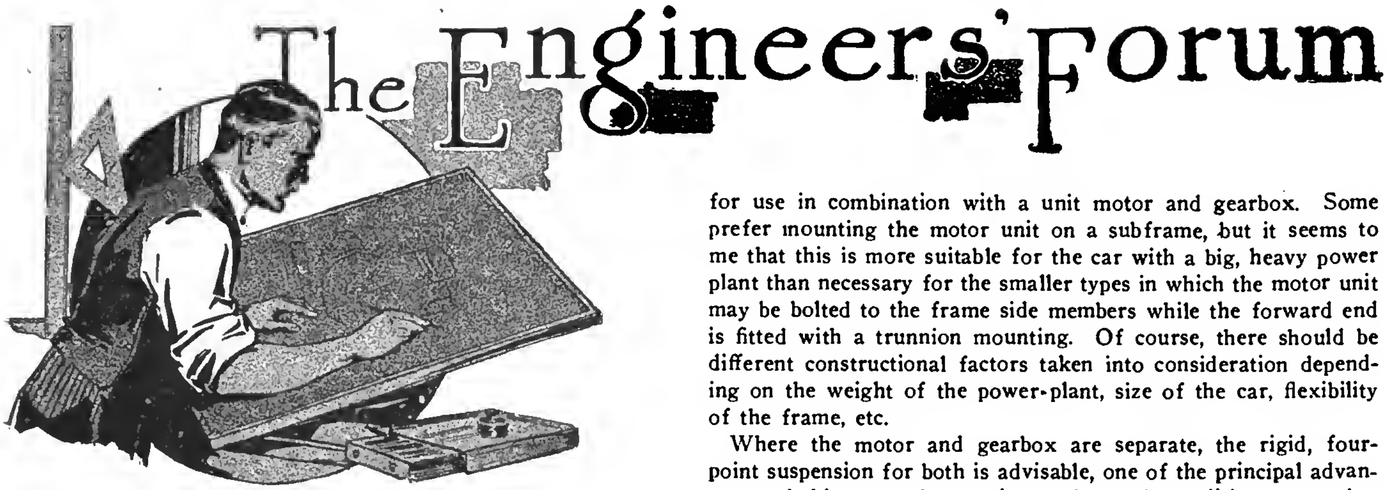
The maintenance cost of the automobile truck was found to be greater than that of the horse and wagon, but the extra amount paid in wages in the case of horse and wagon operation still resulted in a saving of nearly 50 per cent. in operating costs by the use of the truck.

Our records show that the total yearly cost of the automobile truck is about 50 per cent. of the cost of the horse and wagon in doing the same work, which in our case means a yearly saving of nearly $1,000.

The following additional figures in regard to the operation of the truck during the period may be of interest:

Number days of truck operation	94	days
Number hours of truck operation	199.4	hours
Average number hours per day operation	2.12	hours
Total number of miles traveled	2009	miles
Average miles traveled per day	21.4	miles
Maximum miles traveled per day	53.5	miles
Average miles traveled per hour	10.08	miles
Total K.W.H. used	768	K.W.H.
K.W.H. used per day	8.17	K.W.H.
K.W.H. used per mile	0.38	K.W.H.
Energy cost per mile at 5 cents per K.W.H	$ .0190	
Battery renewal and repair cost per mile	.0314	
Mechanical repair cost per mile	.0090	
Tire renewal cost per mile	.0150	
Total operating cost per mile	.0744	
Total operating cost per day	$1.5900	

JOHN A. CLEVELAND, *Saginaw Power Company.*



3-Point vs. 4-Point

G. P. Dorris Likes 3-Point Type of Suspension—Would Like to See Return to Transmission Brake as Emergency Brake

ST. LOUIS, MO.—Editor THE AUTOMOBILE:—Noticing that another instalment of the discussion of three-point versus four-point suspension for motor and gearbox appeared in a recent issue of THE AUTOMOBILE, I herewith submit my views on the subject:

Use a rigid unit power plant, consisting of motor, clutch, transmission and electric systems. Mount this rigidly in a narrow or strangled frame, not to exceed 30 inches, permitting the swiveling of the front axle with the least torsional strain on the frame.

Mount the rear of frame on three-point support platform springs, allowing the rear axle as much freedom as posssible, and the least torsional strain at the rear of the frame. This construction relieves the frame body and power plant of practically all torsional strains, and consequent squeaking and working of body and other ills.

For future argument, I would like to see a return to the transmission brake, as an emergency brake. It should be lever-operated, using the big external rear hub brake as the service brake, as is done in Europe. This system has the following advantages: Lighter rear axle and a smaller amount of unsprung weight.

Less overall weight eliminates the necessity of oiling the brake shafts and the chance of their rusting and seizing. A reduction of brake rods and equalizers eliminates chance of brake rattles—removes necessity of taking off rear wheels to adjust internal brakes. Single rear brakes alternated with transmission brake on long grades, gives divided and better radiation. The external rear brakes are directly accessible for adjustment.—G. P. DORRIS—Dorris Motor Car Company.

Favors Three-Point Suspension

DETROIT, MICH.—Editor THE AUTOMOBILE—I have read with great interest the discussion which has been carried on in the Engineers' Forum recently regarding the advantages and disadvantages of three-point and four-point suspension for motor and gearbox. As the Forum is apparently open to the readers of THE AUTOMOBILE for discussion of various points of engineering practice, I venture to submit my views on suspension.

The three-point type of suspension has always appealed to me for use in combination with a unit motor and gearbox. Some prefer mounting the motor unit on a subframe, but it seems to me that this is more suitable for the car with a big, heavy power plant than necessary for the smaller types in which the motor unit may be bolted to the frame side members while the forward end is fitted with a trunnion mounting. Of course, there should be different constructional factors taken into consideration depending on the weight of the power-plant, size of the car, flexibility of the frame, etc.

Where the motor and gearbox are separate, the rigid, four-point suspension for both is advisable, one of the principal advantages of this type of mounting under such conditions appearing to me to be the preservation of alignment. The firmness of both parts in position and the resulting durability constitute desirable features.

A number of manufacturers make the gearbox integral with the rear axle housing. It would naturally seem that in this type of construction the motor should be mounted in some form of three-point suspension. In this way the inequalities of the road would affect the forward part of the frame before reaching the rear portion where the gearbox is situated and thus the torsional strains which the frame would be called upon to stand would be lessened and distributed more evenly than where these strains fall all at once upon the forward end of a frame which has also to bear the weight of the entire power plant. This construction has other advantages, though it has also some disadvantages, for the added weight of the gearbox increases the strain upon the rear axle housing, etc. Taken all in all, it seems to work out satisfactorily in practice, however.

In the mounting of motor and gearbox on trucks there are different features to be considered, depending on the weight and size of the motor equipment and gearbox, their relative position, the space in which they are to be accommodated, etc.—J. F. BRANFORD.

Correction on Carburetion

In the article on Carburetion in the November 14 issue of THE AUTOMOBILE, page 1002, the specific heat of air should have given as 0.237 instead of 0.259 and the calorific value of the fuel at 288 British Thermal Units per pound, namely $9/5 \times 160$ calories. This makes:

$$\left.\begin{array}{lr} \text{Air} \ldots\ldots\ldots\ldots & 15 \times 0.237 = 3.6 \\ \text{Fuel} \ldots\ldots\ldots\ldots & 1 \times 0.500 = 0.5 \\ & \overline{4.1} \end{array}\right\} \text{Temp. drop}$$

and for 160 calorie fuel $160 \div 4.1 = 39$ deg. C.
for 288 British Thermal Units fuel $288 \div 4.1 = 70$ deg. Fahr.

An Ingenious Danger Signal

LONDON, ENG.—A very interesting device was recently tested and examined by the authorities of Scotland Yard and of the home office in this country. The instrument is styled the Farometer, and it is a machine which has been designed and developed to register in large numbers on a prominent part of a motor-omnibus or taxi-cab the number of miles per hour the vehicle is traveling at any given moment, so that the public may see when a vehicle is exceeding the legal limit of 12 miles an hour in the case of the bus and 20 miles an hour for the taxi-while those carried on the vehicle, as well as the driver, are also shown the same figure. Should the vehicle pass the legal limit a gong sounds to draw the attention of the driver to the fact. If he persists in going faster a red flag appears. the machine being electrically illuminated at night.

Bad Roads Hurt Gearset—Peculiar Case of Short Circuit—Layout for Garage Addition—Sliding Universal Joint—Starting on Magneto System—Broken Connection in Coil Box—Reasons for Heavy Flywheels

Rough Roads Affect Transmission

EDITOR THE AUTOMOBILE:—As I am having trouble with my transmission, due to rough roads, I would like to know if this can be remedied to some extent by putting on wire wheels and larger tires.

2. What is the next larger size tire that can be put on a 3.5 by 34 rim?

3. Would a car equipped with 4 by 32 wheels in place of 3.5 by 34 climb the hills better aud reduce speed on the level? Which tires would wear longer under a five-passenger 2,600-pound car?

4. The rear wheels of my car still have that cracking sound after having been tightened and kept in water. How could this be removed?

Glasco, N. Y. SUBSCRIBER.

—If your trouble is due to poor alignment of the drive shaft and gears, the fitting of wire wheels would not help you. The trouble might possibly be due to a loosening of the rivets connecting the gearset housing to the side members of the chassis. If this is the case it will be necessary to cut out the present rivets, ream the holes and re-rivet with larger rivets. Another trouble might be in the fact that the bearings on the gearset shafts are too far apart or are not of sufficient length or diameter.

2. The next size tire would be the 3.5 by 34 over-sized tire, which could be secured from most of the larger companies.

3. The difference in hill-climbing abilities would not be noticeable. The larger size tire would wear longer.

4. Any wheelwright should be able to remedy this trouble. The cracking sound is an indication of looseness or play in some part of the wheel. This looseness may be in the spokes or it may be in the felloe. Putting the wheel in water will tighten up the spokes for 1 or 2 days, and they will then dry out and be looser than they ever were. The only thing you can do is to take the wheel to a good wheelwright and have a permanent job made.

Short Circuit in Flanders Motor

Editor THE AUTOMOBILE:—I have a Flanders 20, 1910 model. Recently in endeavoring to start the car I threw out the clutch as usual in order to change the speed, and in so doing killed the engine just as though I had thrown off the switch. I have had the engine all down, ground the valves, adjusted the tappets, rewired with new wire and also had a new Stromberg carbureter put on. After having replaced and adjusted everything as nearly as possible, I tried again, with the same result. As long as the clutch is left in the motor runs very nicely, but as soon as you disengage it it stops.

Bloomington, Ill. J. E. CAMP.

—According to the service department of the Studebaker Corporation in New York City it occasionally happens that the spark control rod will be pushed against the breaker box of the magneto, causing a short circuit.

Plan for a Garage Addition

Editor THE AUTOMOBILE—I am looking for an up-to-date sketch or plan for an addition to my garage, which is 50 by 100. I want to add 50 by 100 with clear floorspace, upper floor to be used for paint shop, machine shop, vulcanizing and battery repair room.

Can you give me some light on this subject?

Waukesha, Wis. E. J. FOSTER.

—The best solution of your problem would be to construct, as you suggest, an upper floor on your present garage building. This floor would, of course, have to be 50 by 100 feet like the garage proper, and there should be no difficulty in so arranging the various shops on this floor as to arrive at a very efficient scheme. Since this floor is to be the highest in the building the proper location of windows and skylights to give suitable illumination for the painters and the repair work is a relatively easy thing. We would suggest the following arrangement for the departments which you want to install on this floor:

An elevator is required to bring automobiles from the street floor to the upper one, and it would be a happy idea to locate this elevator in the middle of one of the longer walls so that it projects as far as 20 feet from this wall and has a practically central position. The best place for the elevator would not be at the actual center of the building, but the installation should bear against one of the longer walls, preferably the back wall of the building. In front of the elevator there should be a 10-foot passage through which an automobile may be steered to either side of the floor. The paint shop might be advantageously located to one side of the elevator, giving it the full depth of 50 feet and a width of 40 feet. Two windows each on the front and rear side of the paint shop and three or four in the side wall of the building should give ample light and, if necessary, could be assisted by a 10 by 25-foot skylight.

Opposite to the elevator on the front side of the building a battery room 10 feet along the wall and extending 20 feet into the building should be located, being separated from the rest of the floor by a slidable wire door. Adjacent to the battery room should be a vulcanizing department 15 feet wide and 20 feet deep. This room, like the battery charging department, should have a wire door toward the passageway between it and the elevator. The rest of the floor, practically 1750 square feet, should be devoted to the repair shop, divided into three departments. A tool and stock room, in which small tools and a supply of the most necessary repair parts is kept, is 20 feet square and situated adjacent to the elevator, on the side opposite to the paint shop. A lockable door separates the tool room from the rest of the shop, the department next to it being the machine tool room, in which a lathe, planer, shaper, drill and arbor press and emery wheel should be stationed. This room should be 20 feet wide and should extend from the back wall 30 feet toward the front wall. This leaves a space of approximately 20 by 35 for the rest of the repair shop. In this room, benches ought to be arranged alongside the windows, and a useful addition to the equipment would be a stand 4 feet above the ground and fitted with inclined runways on which an automobile may be moved up to the stand. This piece of equipment adds greatly to the ease of repair work and enables a man to do more work in a given time on a car with less fatigue than otherwise.

Depending on whether you think that this addition to your garage would be final or whether you expect to increase it again at some later date, the construction of the upper floor should be made lighter or more substantial. This point determines also the construction of the elevator shaft; if the upper floor will be the last addition to the building the elevator might open toward three sides of the room, being supported on structural beams positioned in the corners of the shaft; whereas if you expect to add another floor in the future only the front side of the elevator shaft should be open, the two sides being formed as walls, which aid in supporting an additional floor if the latter is built on the second story which you now intend to erect.

National Uses Sliding Universal Joint

Editor THE AUTOMOBILE:—Would you kindly tell me what type of universal joint is used on the National 40 car and what the different parts which go to make up this joint are named?

2. I have been troubled with a squeak from the worm and gear steering on my car, it is carried on ball bearings and I do not understand why it should give me this trouble. How can this be remedied?

Baltimore, Md. E. SUMMERFIELD.

—1. An illustration of this universal joint is given in Fig. 1. The upper shaded view shows the sliding portion while the lower view shows a large part of the assembly detail. The universal joint consists of a main steel portion attached to the gearset shaft by two keys. It revolves on the annular ball bearing shown in the illustration. The driving shaft is turned to a ball shape and has the hardened pin shown in both views running through it. Upon this pin work the two steel squares shown in the lower illustration. These slide within slots in the main portion of the joint and give the joint its name, sliding. A metallic housing incloses the joint and likewise a plentiful supply of grease for its lubrication.

2. The squeaks in the steering gear are due to a lack of lubrication between the worm and the gear. If you will pack the gear housing with grease the trouble will be removed. The general arrangement of the parts is shown in Fig. 2.

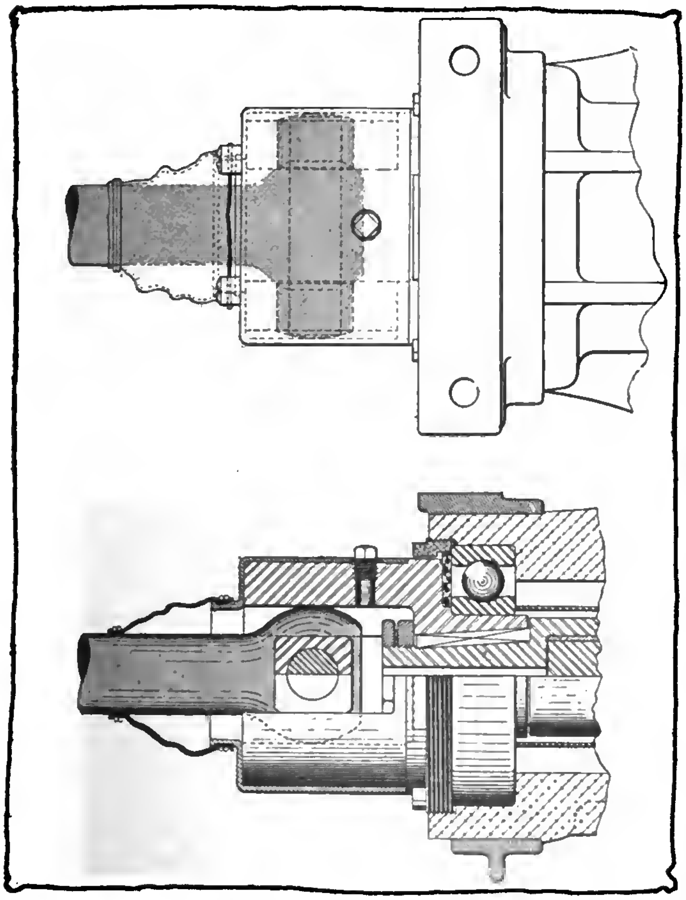


Fig. 1—National universal joint of the sliding type used on 40-horsepower cars

Removing Chalmers Valve Caps

Editor THE AUTOMOBILE:—I have a Chalmers 36 and am about to grind the valves. Can you tell me how I can remove the valve caps? The instrument supplied with the car slips off when I begin to pull on it. I cannot start the caps with a cold chisel and hammer. Is there any wrench made that will fit these caps or can you tell me how I can have one made?

Salem, Mass. H. S. L.

—The New York agency has an extensive repair shop in which it repairs nothing but Chalmers cars. In this shop the method used for removing these caps is by placing a brass bar against them and hammering on the bar. The use of a cold chisel for this is bad because it will chip off the metal while the brass being softer will not harm it. It has been the experience of this shop that there are no valve caps which cannot be removed by this method, although some are much stiffer than others.

Weight of Flywheel Required

Editor THE AUTOMOBILE:—Can a six-cylinder motor be made with a flywheel of materially less weight than that used on a four-cylinder motor? Is it possible for an eight-cylinder motor to run without a flywheel? Why is it that a flywheel must be installed in a gasoline engine, and not on an electric motor? Is it because the revolving armature takes the place of the flywheel?

Philadelphia, Pa. L. F. RENBER.

—An increase in the number of cylinders lessens the necessity for a flywheel, but even with eight cylinders it is necessary to have some sort of rotating balancing member in order to get smoothness of action. With a single-cylinder motor the weights of flywheel used with automobile engines have run up as high as 1200 pounds, and in stationary motors the weight has gone far above this in order to get perfectly smooth action without jar when the motor is crossing dead center. In automobile practice flywheels on multi-cylinder motors are reduced for as small a size as possible and still secure even running, the greatest trouble being to secure a perfectly smooth action when crossing dead center under a heavy load causing the motor to turn over slowly. In average practice the flywheel on a four-cylinder motor of about 30 horsepower will average somewhere around 80 pounds. For a six-cylinder motor it will often be as low as 60 pounds, while motors with a flywheel of less weight than this have been made.

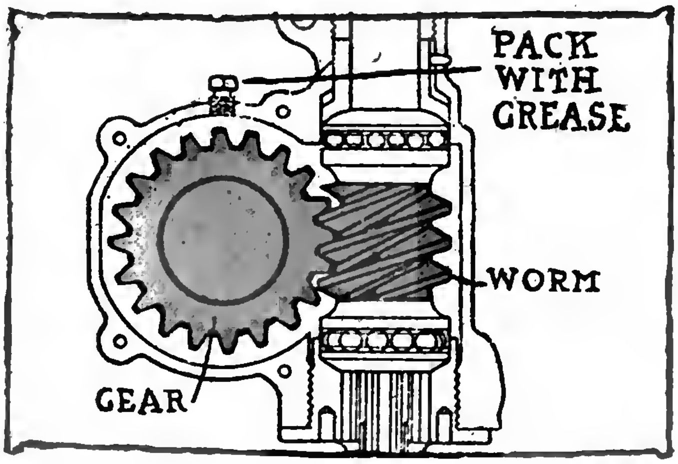

Fig. 2—Indicating point in worm and gear steering where grease should be applied

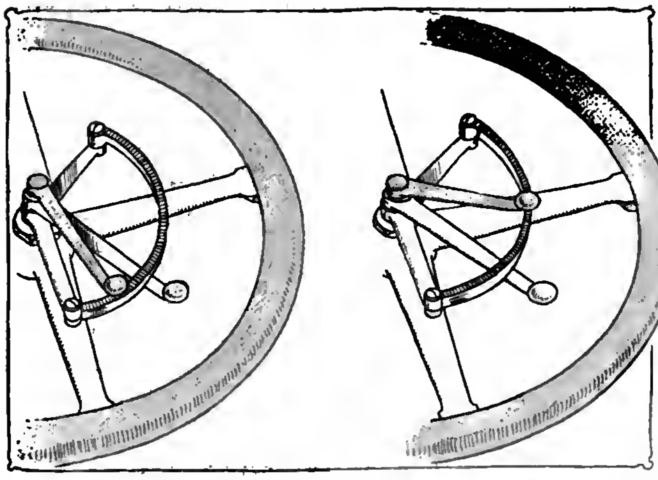

Fig. 3—Shaded levers show position of spark advance when started; left for battery, right for magneto

The weight of the flywheel required depends to a large extent on the balance of the machine itself as well as on the weight of the reciprocating parts and their distribution around the axes of the crankshaft. The reason a flywheel is not required on an electric motor is because the impulse is constant and there is no dead center over which the armature must be carried.

Curing Ford Clutch Trouble

Editor The Automobile—I have a Ford model T which has run about 6,500 miles, and wish to overhaul it.

1—The engine knocks, especially when pulling hard. Do you think this is due to carbon deposits in cylinder?

2—Do you think it necessary for the cylinders to be ground?

3—The clutch does not act as quickly as it should. I have tightened it, but that does no good. Is there any danger of having it too tight?

4—How many miles will the differential gear last in this make under good care?

5—Should this car run almost like new when overhauled?

Piqua, Ohio. M. O. F.

—1. The trouble evidently is in the fact that you have carbon in the cylinders. The carbon should be scraped from the cylinders and the valves ground.

2. If the valves have not been ground since you have had the car they are now probably in need of grinding.

3. The high speed adjustment should be tightened. The three set screws on the gear case should be given a one-half to a full turn, each screw being given the same adjustment.

4. This depends altogether on how the car is driven. Taking corners at high speed and otherwise abusing the car may materially shorten its life.

5. When thoroughly overhauled the car should run as good as new.

Starting on the Magneto

Editor The Automobile:—How is it when you wish to start on the magneto it is necessary to advance the spark lever from one-half to two-thirds the way on the quadrant? When this is done, where does the spark occur; before or after dead center?

2. Where does the spark occur when the spark lever is fully advanced?

3. What is the advantage of having cells (dry) in multiple series?

Boston, Mass. Subscriber.

—The reason that the spark lever must be advanced when using the magneto is because the lag of the spark is much greater in the magneto than in the battery. This is due not only to the actual lag of the magneto but also to the relative lag caused by the motor being turned over rapidly or spun when started on the magneto. The relative positions of the spark lever when starting by battery and magneto are shown in Fig. 3. The shaded levers in this illustration are the spark levers. The spark occurs at about dead center.

2. When the spark lever is fully advanced the spark occurs before dead center is reached. The maximum of advance is in the neighborhood of 35 degrees before dead center on the average touring car.

3. When the cells are connected in multiple series they last longer than if connected in series. So much current is contained in each cell and when these cells are increased in number a greater supply of current is available. When this supply is removed at the same rate or in other words when the same amount of current is consumed at the same time the greater number of batteries will last longest. Hence it is that a multiple series connected last longer than a single series.

To Find Gas Leaks in Motor

Editor The Automobile:—Could you tell me of a good method by which to locate the leaks in a gasoline motor. If the leak is very elusive I find that it cannot be exactly determined by the process of putting oil or soapy water on the different joints and connections, except by mere chance.

Chenango, Mich. Carl Spirone.

—First flush out each cylinder with about a pint of kerosene oil, after shutting off the gasoline from tank; then drain the crankcase to get the kerosene out of it. Now cut out the ignition, and be mighty careful you cut it out, or later, when you are pressing down on the starting crank, you may find a 30-40 horsepower kick which will most likely injure your arm if not break it. Close up tightly all priming cups, and on cylinder No. 1; take an oil can filled with kerosene and flood the plug from top to bottom, being sure to get enough oil in and around the base of the plug so that any escaping air will cause a bubble to appear when you tnrn the engine over its compression. Be sure you put the kerosene around the priming cup also, for these leak a trifle at times where they are seated, and any leak, however small, will cause trouble in the proper running of the motor. After you use the oil, take the starting crank and press it slowly downwards, at the same time watching carefully the cylinder and priming cup for any air bubbles which may appear. Repeat until all cylinders are tested, being careful not to skip any one of them by looking at the wrong one under compression. It is more certain to open all relief or compression cocks except the one you are testing, closing them as you progress with the work. If a bubble appears between the shell of the plug and porcelain or mica, it is evidence that the plug needs tightening or a new gasket fitted. If the bubble appears at the seat of the plug it is evidence that the plug is not properly seated and needs to be taken out and a good coat of flake graphite mixed with cylinder

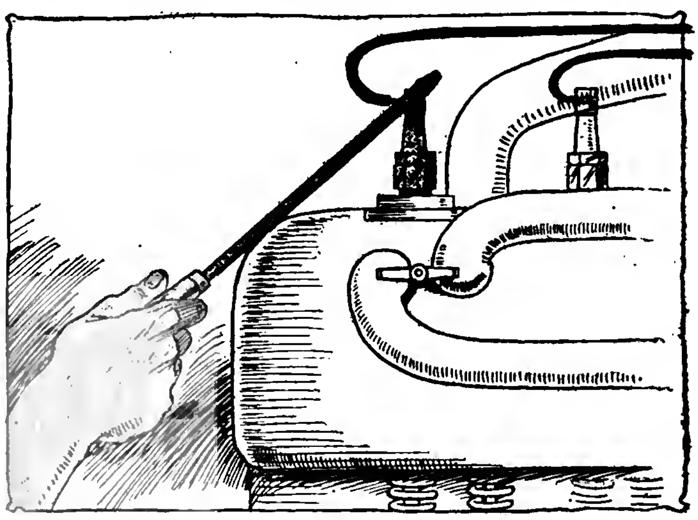

Fig. 4—Short circuiting plug to detect which cylinder is missing

oil, to the consistency of putty, placed all over the threads of the plug. Then screw it carefully into its seat, not too tightly, as this would cause it to crack its porcelain and cause it to stick at times. If you have no new gaskets on hand you can make as many as you please by taking a piece of asbestos and a pair of shears and cut out a round ring to fit over the porcelain and then screw the packing nut tightly home. If you test for these slight leaks you will be surprised at finding them when you least expect to do so.

Bad Connection in Coil Box

Editor The Automobile:—We have a Rambler model 53, sold in 1910. It has a Splitdorf vibrating coil and we cannot crank the motor on this coil or battery side, but if we will press on the starter button on the side of the coil box we get a good spark at the cylinder. If we crank this motor on the magneto it will run as well as ever, but when the switch is on the battery side it will stop at once unless the button is pressed on the side of the battery box. As long as this is done the motor will run as well as ever, but the moment we stop pressing on this button it will stop. When switched on the magneto is runs well. The batteries are good (testing 28). The vibrator points are clean and we get a good spark at the plugs when we press the button, but rarely get one when not pressing the button.

Can you help us out of this trouble?

Iuka, Kan. Maynard & Phillips.

—The trouble is in a broken connection in the coil box, the spring not being in contact with the rest of the circuit. When the starting button is pressed the contact is made and hence the motor will run. The box cover should be removed and the spring bent up slightly, or the coil should be sent to the Kansas City Splitdorf agency, where the disconnected parts will be put in good order.

Wiring Used on Six Cylinder Cars

Editor The Automobile:—What is the best wiring scheme to use on the 48-horsepower six-cylinder Pierce Arrow car?

2. How can you detect which cylinder is missing on a six-cylinder car?

New York City. Jerome Wilson.

—The wiring diagram which depicts the wiring scheme more clearly than it could be described is shown in Fig. 5.

2. If you will take a screw-driver, place it first against the metal of the cylinder and then against the tops of the spark-plug in the manner shown in Fig. 4 you will be able to detect which cylinder is missing fire. The method of procedure is to do this with each cylinder in turn, noting the effect. Whenever you reach the cylinder that does not indicate any effect or difference in the running when the plug is short-circuited in this manner you will find the one which is misfiring.

Engineer on Ether for Starting

Editor The Automobile:—Having seen a number of requests lately in your journal regarding the action of ether as a primer for starting in cold weather, it may be of value to your readers to know that I have used for this purpose for the past 7 years a mixture of one-half gasoline and one-half "commercial" or "washed" ether.

The mixture is placed in an ordinary half-pint can with a cork over the tip when not in use.

I squirt about one-quarter ounce of the mixture into each priming cup and have never known any motor to fail to start with one-quarter turn of the crank, that is, one pull up.

I have had the motor occasionally start on the spark even in very cold weather.

I have absolutely no bad effects from its use in any way.

Contrary to a popular impression ether does not cause abnormally high pressures in the cylinders.

The washed ether costs 35 cents per pint at wholesale drug-

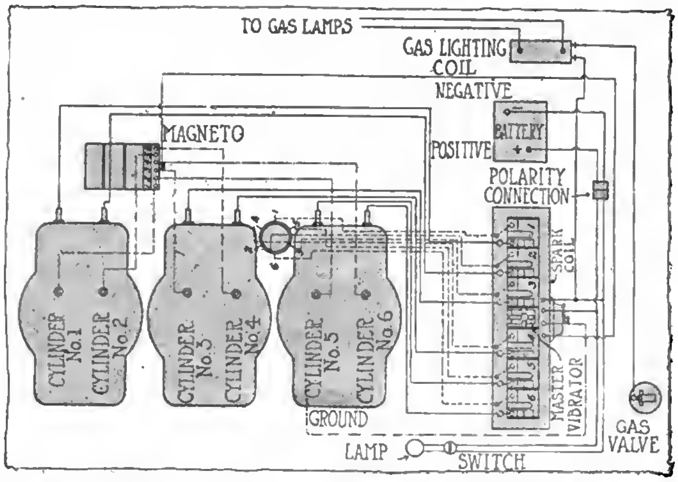

Fig. 5—Wiring diagram for ignition and gas lighting as used in the six-cylinder Pierce-Arrow 48, 1912 model

gists and comes in sealed tin cans. Two pints will usually last me through the winter, so that the expense thereof is but a trifle.

Detroit, Mich. Edward T. Birdsall, M. E., Consulting Engineer.

Blames Low Test Fuel

Editor The Automobile:—I have two cars which seem to lose much power in cold weather, yet they seem faultless in carbureter, ignition and compression. I blame much of this trouble on low test gasoline which I find tests as low as 59. Would you consider a higher test gas, say 73-76, would be better for use in winter when cars are usually cold? If so, kindly explain in what way, also if it is quicker and better at any time. I also have trouble in plugs becoming sooty.

2—I note the Standard Oil Company marks its shipments of 73-76 gasoline "Naptha." Has that any particular significance?

I am not prone to pay a high price to get a high test gas but would prefer to do so if it is much superior. Please advise through Letters Answered and Discussed.

Whitehouse Sta., N. J. J. H. Dilts.

—In cold weather a car will never pull well until the motor becomes warm. If the radiator area used in winter is the same as that used in summer it stands to reason that the motor will run cooler and hence with much less efficiency. Therefore, it is necessary to cover the radiator in cold weather to prevent the radiation of the heat from the motor. If this is done you will find that a short time after starting the motor will pull as well in winter as it does in summer. As a matter of fact, there is more power in the lower test fuel than there is in the higher and after once getting the motor started, the lower grade will give good satisfaction. If you are burning too rich a mixture or using oil which is just as heavy as that used in summer, the trouble with the plugs is explained. Try a lighter grade of lubricating oil.

2—The name given by the oil concerns to the gasoline used in automobiles is auto-naptha. This is merely a name and has no special significance any more than it marks a certain limit in the distillation. That is, it indicates that in the refining process the cut, or lower limit of the refined product has been set at a definite point.

—

The Editor of this department is holding numerous letters signed Reader, Subscriber and by various initials which cannot be answered until the name of the sender be known. Owing to the large number of inquiries received many letters are answered by mail instead of through these columns; those of general interest being selected for the latter purpose. Anyone may receive a direct reply by mail by stating their desire and enclosing postage.

Electric Cranking and Lighting

Part I

Giving An Elementary Review of the Requirements of a Complete Electric System and a General Introduction to the Subject Before Taking Up a Consideration of Each System

Subject Digest

¶ For electric cranking it is necessary that a supply of current be on hand to operate the cranking motor for a sufficient length of time to start the engine under the most adverse conditions. Since there are no moving parts before starting the engine the source of the current must be a battery.

¶ The length of time that a battery can supply current for any purpose is limited; therefore, it is necessary that some means be provided to replenish the current drawn from the battery after it has started the engine by means of the cranking motor. The means must be generator mounted on the car because an outside source is impracticable.

¶ Three types of electric system are used. The single-unit system combines in one instrument the generator for lighting and ignition and the cranking motor. The double-unit system combines any two of these and has the other unit separate. The three-unit system has the generator, the cranking motor and the magneto separate.

¶ Each unit must be protected and regulated so that it will be impossible for it to be damaged or to cause damage.

WITH the adoption of electric cranking on 69 per cent. of the cars which are using starters at all, the problem of proper electric installation both from a standpoint of standardization and good practice, becomes highly important. On such a car the primary requirement is that electric current must be available for three purposes—namely: ignition, lighting and cranking.

The requirements of the ignition system, when independent, are few and have been solved in the past. The sole duty of the ignition system is to supply a current at the electrodes of the spark-plug of such strength that it will cause a spark to jump across the gap. The source of the current may be either a battery, a magneto, or a device performing the functions of the latter.

For lighting it is necessary that a continuous flow of current be delivered at the lamps. The current for the lamps must maintain a steady pressure or voltage in order that the glow of the lamps will be uniform and that the filaments will not be destroyed owing to excessive pressure or, in other words, voltage. The source of supply may be from a battery or a generator.

For electric cranking a current must be drawn by the cranking motor which will be of sufficient quantity to turn the engine. **The sole purpose of the electric motor is to crank the engine, and when through with this work the current need not be supplied to it. Therefore, the current must be controllable by the driver.** The source of this current must be a battery because when the cranking is required there will be no units in motion, and hence nothing about the car which can generate the current necessary at the time.

The above three paragraphs show that the battery may supply current for either cranking, lighting or ignition.

Since the length of time that a battery can supply current is limited, and since for at least cranking and lighting the battery must be always available, it is evident that there must be a means of producing electrical energy which will replace that taken out. This energy may be either from an outside source or it may be from a generator of electric current on the car itself. Discarding the outside source as obviously impractical and unhandy, only one alternative remains, namely, to mount a generator on the car. Since it is impossible to store an alternating current in a battery the generator must supply a direct current.

It should be noted here that a magneto is a generator which supplies an alternating current, and therefore could never be used for storing a battery. For that reason alternating current generators are not used for auto lighting.

A direct current generator supplies a current which may be used for storing electric energy in a battery, for ignition purposes and for lighting purposes. It is therefore evident that a battery and a generator used in conjunction with one another are sufficient to maintain a supply of current at the disposal of the operator of the car for any purpose to which he wishes to put it.

From what has been said it may be seen that there are three units necessary for an electric cranking system. First, a battery which may be compared to the water tank on the top of a house which holds a supply that may be available for any purpose whenever it is desired to draw it off. Second, a generator which has its parallel in the water pump which raises the water into the tank. Third, the cranking motor which is like the water wheel or water motor which is operated by the water in the tank. The switches controlling the supply of current and its application may be directly compared to the various valves used for turning on and off the water and for controlling the direction of its flow.

Regulation and protection of the various units of an electric system are necessary in order that they continue to bear the proper relationship to one another under all operating conditions.

The battery must be protected in two ways: First, against discharge of the current contained at improper times or when the battery is not in use. Second, against the injury which would result should the battery be charged too rapidly. This occurs when the outside source supplies the current at too high a rate or when the generator on the car is driven rapidly at high engine speeds, such as in fast running or hill climbing. These two danger points are the same as those which must be guarded against in the case of the water tank, to which the battery is comparable. It must be guarded against the leakage of its supply when the pump is stopped or against being filled so rapidly and by such a violent stream that the water is thrown out of the tank or even, in an extreme case, destroys the tank itself.

The electric circuit, of which the lamps are a part, must be protected against an excessive voltage, or electrical pressure, which would burn out the delicate filaments of the lamps. These would be destroyed first because they are the weakest part of the circuit.

The protection of one unit in an electric system is secured by the regulation of others. To prevent the battery from allowing its charge to pass back through the generator when the latter is stopped, a reverse current cutout is used. Its use and purpose correspond exactly to that of a ball check valve, which permits the water to flow from the pump into the tank on the house, but prevents its return back through the pump when the pump is stopped.

The protection of the battery against an excessive charging rate is accomplished by regulating the generator in four ways, as follows:

1—Mechanically, by a centrifugal governor and a clutch which is allowed to slip as the speed of the engine increases. This is shown diagrammatically in Fig. 5.

2—Electro-magnetically, by the changes in magnetic power of an iron core due to the variations in the current passing through a coil wound around that core and the electrical output is made a function of the engine speed. Generally the magnet acts against a spring and extends or compresses it in proportion to the power of the magnet. This method of regulation is shown diagrammatically in Fig. 5. This control of electrical output may be a function of the speed in one case or of the pressure or voltage in another.

3—Inherently, by making the generator in such a manner that throughout the range of working speeds a nearly constant current output is produced. This is accomplished by compound windings which operate against each other in such a manner that the resultant is always the same. It may be compared to a man rowing against a stream whose current is swifter toward the center. If he moves against the stream at a constant rate he must row more rapidly as he gets into the faster current, but the difference in his actual speed and the speed of the current will be constant.

4—Thermally, by the increase of resistance due to a rise in the temperature of a conductor, the increase coming into play when the generator output is too great. It requires more energy to send an electric current through a wire when it is hot than when cold. Advantage is taken of this principle in one method of regulation.

With the system in mind as so far outlined it would be well to turn to a complete hydraulic parallel with an idea of showing clearly the relative conditions which must obtain between each member of the system. The diagrammatic layout in Fig. 4 shows this completely. The battery is represented by a storage tank, the generator by a pump, the cranking motor by a water motor or water wheel, the lamps by small water wheels, the switches by hand-operated valves, the reverse current cutout by a check valve, the generator output regulator by a governor, which disconnects the pump when the speed becomes too great, and the wires by pipes.

With a clear outline of the electric system in mind the study of its operation and manipulation becomes simply a matter of taking up the action of each unit. With the system stationary the first move must be caused by the current which is in the battery. It is necessary to draw on the supply which has previously been stored there. There must be sufficient current in the battery to operate the cranking motor for a sufficient length of time to make starting certain under the most adverse circumstances. Given the source of electrical energy and the necessary units with which to transform the same into work or vice versa, the application of the principles is all that remains.

Electric systems on automobiles may be classified according to the grouping of the elements of which the system is made up. There are three systems, the single-unit, the two-unit and the three-unit.

The single-unit system—In this system the cranking motor and the generator are combined in one unit which is known as a motor-generator. In addition the generator portion of this unit performs the functions of a magneto.

The two-unit system—The two-unit system is subdivided into two classes:

A—Where the cranking motor and the generator are combined in one unit and the magneto forms the other. In this system the units are known as a motor-generator and a magneto.

B—Where the cranking motor and the generator are separate units and the generator performs the functions of a magneto; or, in other words, supplies the current for ignition.

The three-unit system—In this system the cranking motor, the generator and the magneto are all separate and distinct units.

The different classifications may be brought out diagrammatically.

In applying the different units to the engine certain laws of

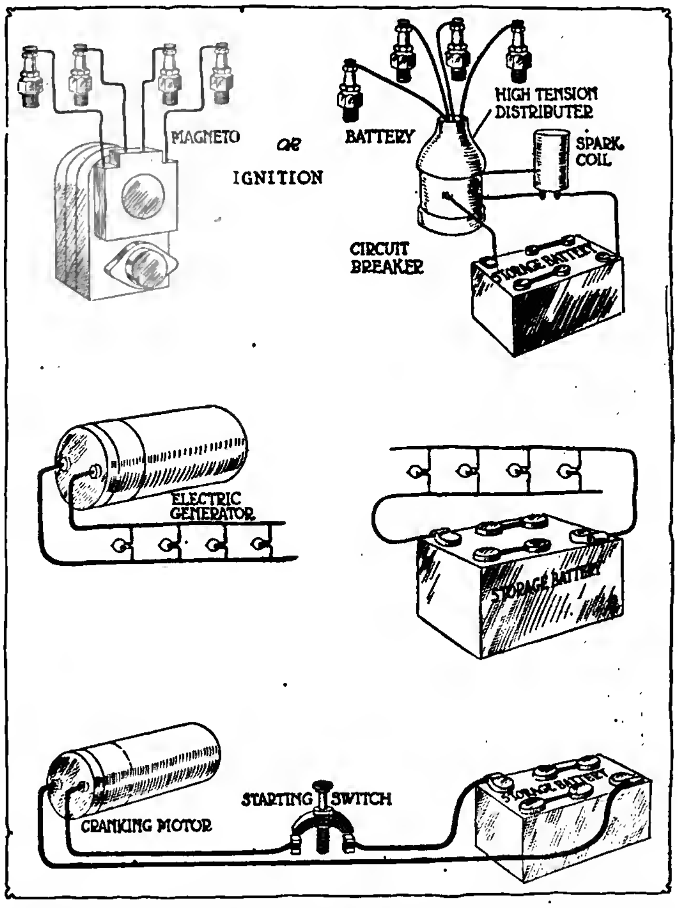

Fig. 1—The fundamental requirements of electric ignition, lighting and cranking. Top—Magneto or battery furnishing current for ignition. Center—Generator or battery furnishing current for lighting. Bottom—Battery furnishing current for electric cranking

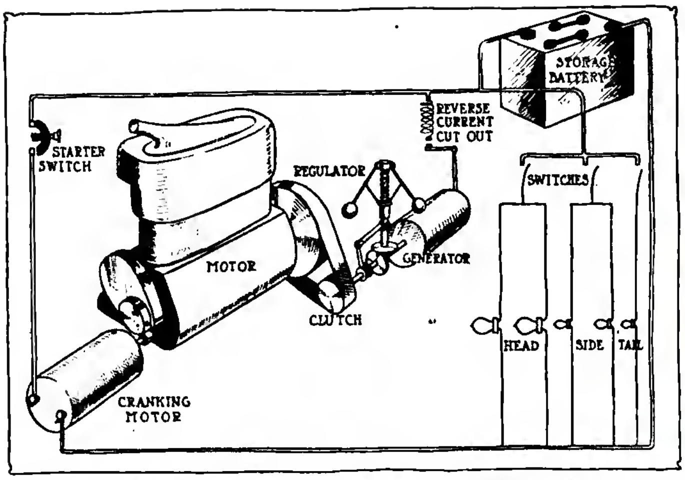

Fig. 2—The elementary layout of an electric starting and lighting system

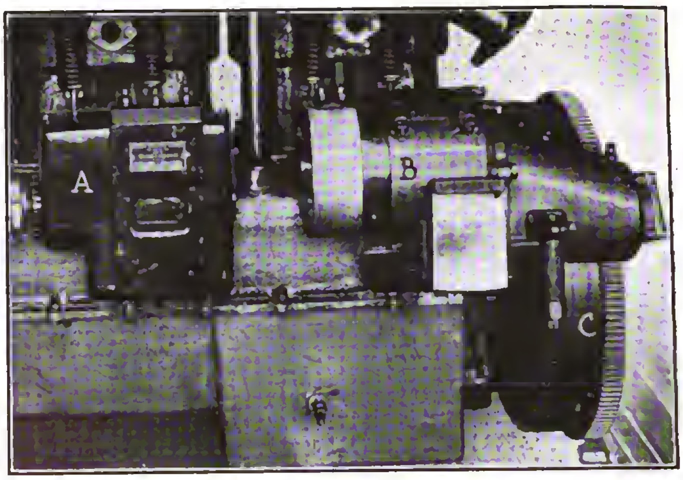

Fig. 3—The installation of the Locomobile cranking motor B on flywheel C

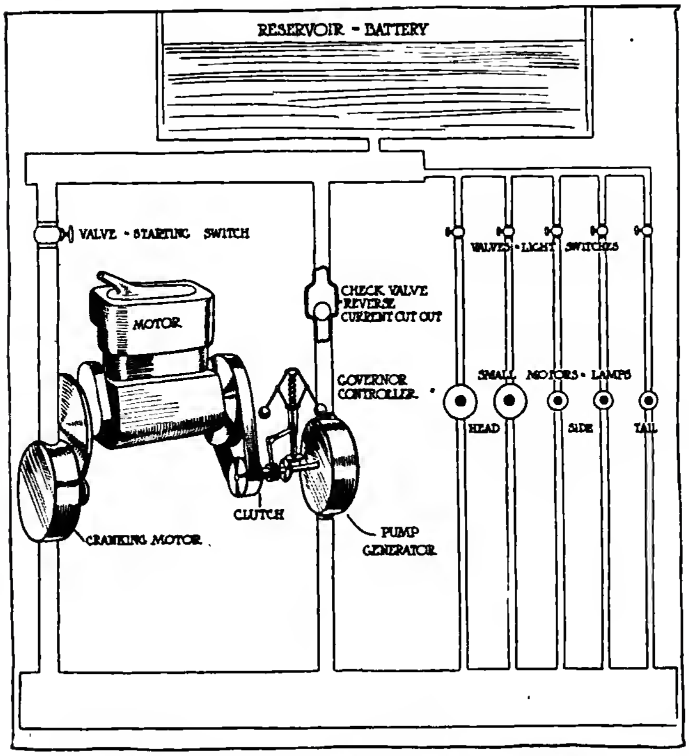

Fig. 4—Diagram showing hydraulic parallel of an electric ignition starting and lighting system.

relationship must self-evidently hold; these may be stated as follows:

The generator of the ignition current must bear a constant relationship to the engine crankshaft for proper ignition timing. Every time the crankshaft of the engine is in a given position the ignition-current generator shaft must be in a fixed, definite position in order that the spark will occur at the proper time.

The generator for the lighting current need not bear a constant relationship to the engine crankshaft, although the gear ratio between the two will be constant for any given installation. The difference is caused by control features which will be explained later. These permit the driving mechanism to revolve more rapidly than the driven. The gear ratio between the generator and the crankshaft varies between 1 to 1 and 4 to 1.

The cranking motor may be installed in any number of ways. It may rotate at crankshaft speed or at 100 times crankshaft speed, i. e., from no reduction to 100 to 1 reduction. When not needed for cranking the motor and when mounted as an independent unit, the cranking motor is at rest. A motor-generator may run at two speeds: first, when operating as a generator, and, second, when operating as a cranking motor; it must also have an automatic means for making the change. The devices used for this purpose are roller clutches, eccentric gears, epicyclic gears, etc. The object of these devices is simply to use the most advantageous speed for the motor when used as such and then to change to a speed which would be suitable for the generator.

To sum up the situation, it may be stated with the above gear ratios in mind that in the single-unit system the single instru-

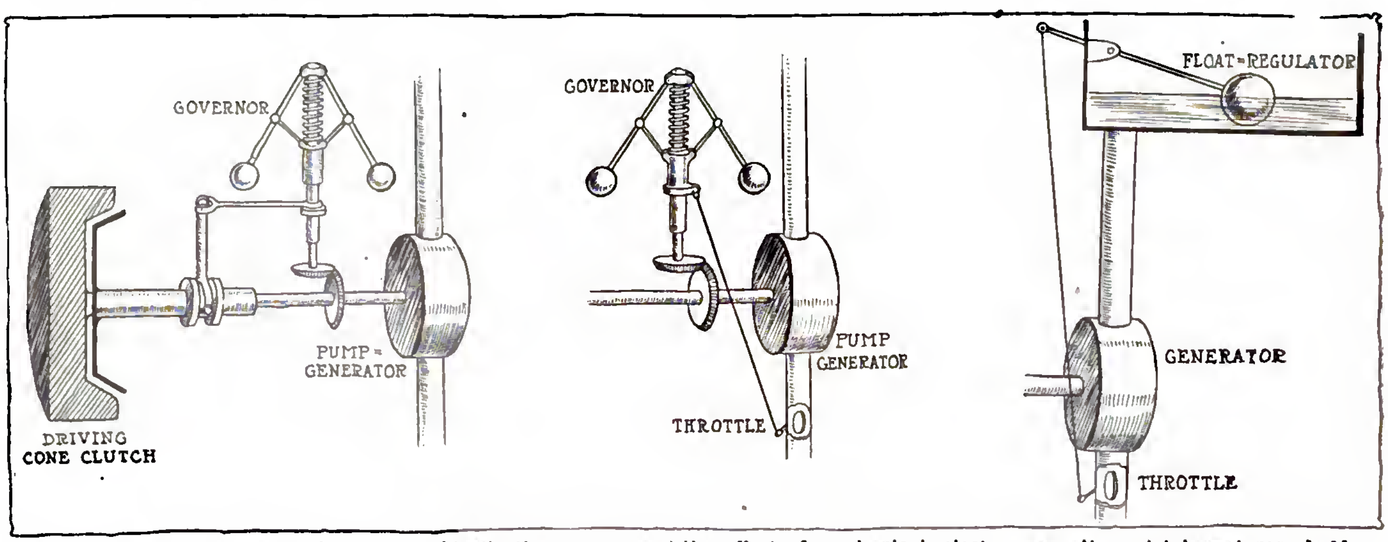

Fig. 5—Mechanical diagrams, showing graphically the purpose and the effect of mechanical, electro-magnetic and inherent regulation of generator output

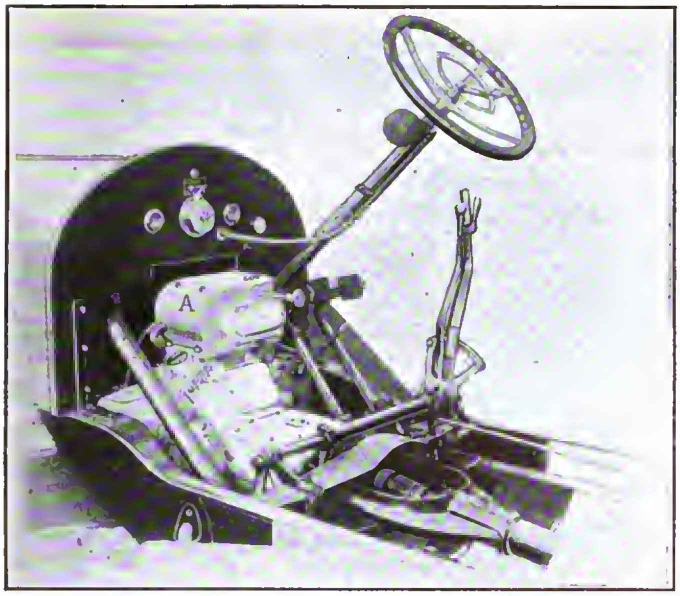

Fig. 6—Pathfinder installation with motor-generator, A, on flywheel

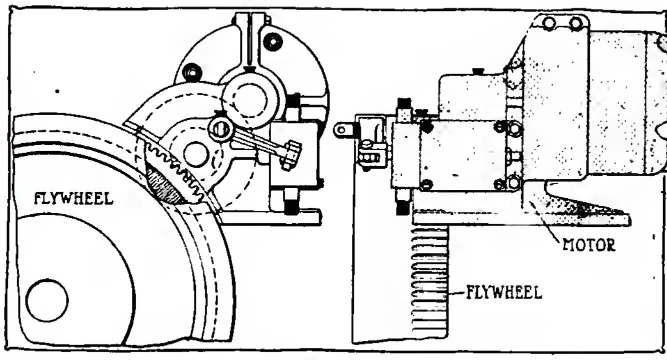

Fig. 7—Mounting of the Elyria-Dean cranking motor on flywheel of engine

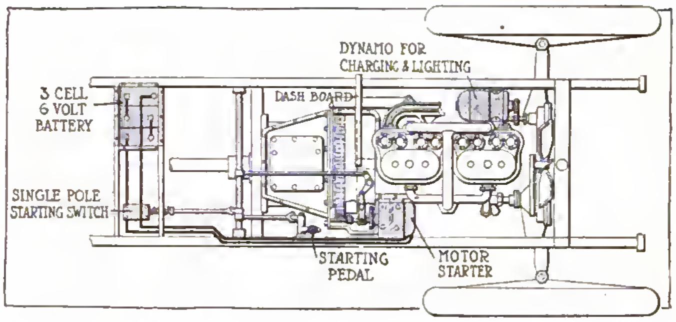

Fig. 8—Gray and Davis installation, showing wiring and location of parts

ment is in positive engagement with the engine and rotates whenever the latter is in motion.

In the motor-generator two-unit system the motor-generator is in positive engagement with the engine and rotates whenever the latter is in motion. The magneto does likewise. When the magneto is incorporated with the governor and the cranking motor is separate the generator rotates with the engine while the cranking motor is only in engagement with the engine when it is desired to start.

In the three-unit system the cranking motor is only in engagement with the engine when it is desired to start. The generator and the magneto both rotate with the engine.

In all three systems it may be noted in summing up the situation that, unless the cranking motor be incorporated with the generator into a single unit, the cranking motor will be in engagement with the motor only when cranking and when the engine is running under its own power the cranking motor will be at rest.

The methods of connecting the cranking motor to the engine are at the present moment a matter of concentrated study on the part of both the car manufacturer and the designer of the electric system. The life of the cranking system depends to such a degree on its installation that this matter is of supreme importance. The problem of motor-generator reduction gearing has been met by the following methods: planetary gearing, eccentric gearing, direct connection and silent chain. The first two allow of different speeds when used as a motor or generator. When the cranking motor is separate from the generator it may be direct connected, through spur gears, by worm gear, by slid-

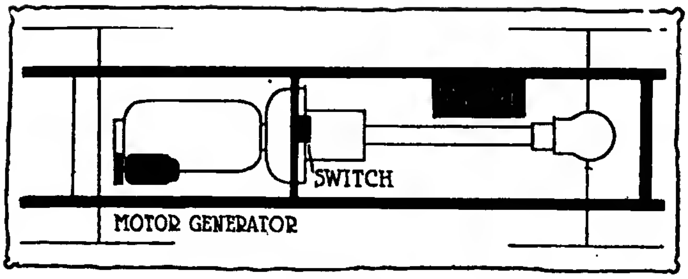
ing gear or by silent chain. Direct connected motor generators are commonly mounted in or replace the flywheel and perform its functions.

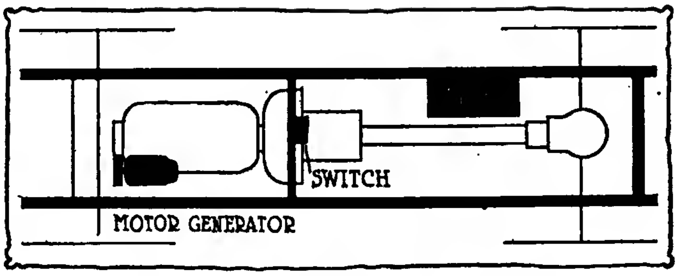
Since, when the cranking motor is separate from the generator, it is disengaged from the engine, the driving mechanism must be supplemented by some device which will disengage it. This is generally in the form of an overrunning clutch. Besides this it may also have a kickback release which is so designed that when a back kick occurs the cranking motor is automatically disengaged. Some type of anti-clashing device which prevents injury to the gears in engaging and releasing is also a part of the installation on some cars. In some instances the device which prevents the clashing of the gears is incorporated in the control mechanism.

After considering the connection of the cranking motor to the engine, the connection of the storage battery to the cranking motor should be considered. The connecting link between the battery and the cranking motor is the starting switch. These switches are of three types: the knife switch, the laminated switch or the two-point switch. The first two mentioned are common switch types and need no explanation, the two-point switch, however, should be explained. The first point in the switch and the second point are connected by a resistant material. When the switch is closed at the first point the complete circuit is closed, but the current must pass through the resistance between the first and second points. When the second point is closed the resistance no longer comes into play and the obstruction to the current is removed. The object of the two-point switch is to allow the cranking motor to revolve slowly at first in order to secure a perfect mesh of the gears without the clash which might occur were it attempted to mesh the gears when the cranking motor was revolving rapidly.

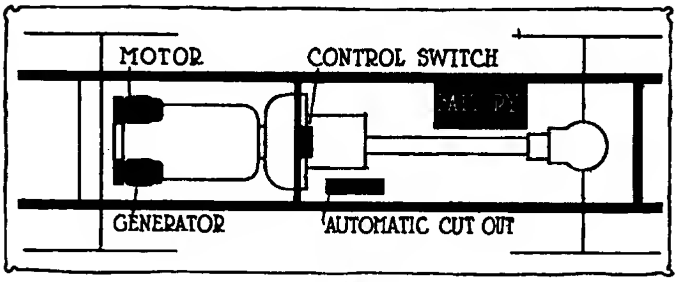
As far as the operator is concerned the devices which he must use to control the starter should be simple and also sightly. They must be simple in order that a driver who is not a mechanical genius may be able to operate the system without damaging it and they must be sightly because the mounting is generally in a conspicuous or at least exposed position. Two types of controller as usual, although there are several variations in isolated cases. The two usual types are the foot or hand push switch and the lever switch. The foot switch is placed on the floor of the car in such a position that it may be readily reached by the foot of the driver. On some cars it takes the place of the muffler cut-out. The lever switch is used very commonly with two-unit systems. The running position of the lever is generally down or in, and when in this position the motor-generator is in continuous operation. When the car is traveling less than a



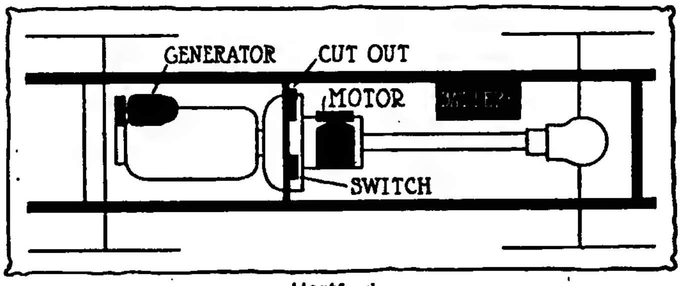
Electro



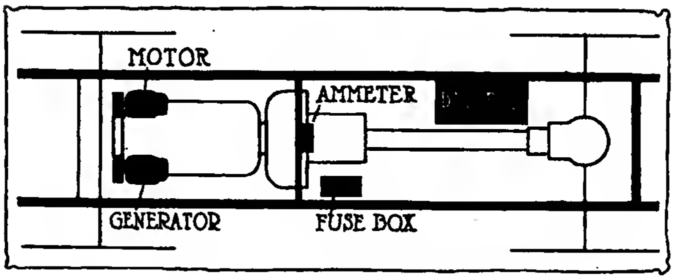
Northeast



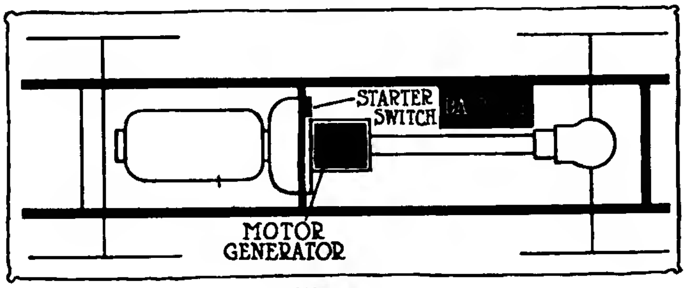
Deaco



Hartford



Auto-Lite



Warner

certain speed the motor-generator is acting as a motor and is aiding in the propulsion of the car. When the speed mounts above a certain point the motor-generator acts in the capacity of a generator and charges the storage battery. When the lever is up or out, electric connection between the battery and the generator is broken.

The question of wiring is an important one. Given a system which operates at 6 volts, the wiring should be of low enough resistance to deliver the 6 volts at the terminals. With a larger wire than necessary the resistance to the current is so great that in some cases it will render the system inoperative. The voltages used in electric cranking and lighting systems range between 6 and 24. Where the lighting voltage is different from the cranking voltage, different wire is often used for the two systems. The three-wire system is common with many of the lighting systems. Where a 24-volt battery is used and the lights are operated at 12 volts a wire is run from the center of the battery so that the difference in potential between the end wires and the center or neutral wire is 12 volts. The wires are then strung across between the end wires and the center wire.

—

Charging of batteries should be begun at the highest rate given in the instruction of the makers and should be continued at that rate until gassing sets in, when the rate of charging should be reduced to such a degree that the development of gas ceases and continued at that rate. When gassing begins again the rate must be reduced once more and then the battery is charged the full capacity, at the so-called finishing rate, which is also given in the instructions accompanying the battery when received from the manufacturer. Another important point is that the battery should not be left standing idle or rather in discharged state, as the formation of a lasting or at least stubborn deposit of lead sulphate is apt to be the result of such a treatment.

Late Developments in the Contest Field

Teddy Tetzlaff Disqualified as Racing Driver Till May 28
Chicago Club's Novel Reliability To Be Run June 25-28
Eighteen Racing Cars Entered in the French Grand Prix

AT a meeting of the Contest Board held at A. A. A. headquarters, Friday, Jan. 10, at which were present David Beecroft, P. D. Folwell, H. W. Knights, Frank G. Webb, Wm. Schimpf, chairman, the following action was taken:

The automatic disqualification of Teddy Tetzlaff, of Los Angeles, registered racing driver No. 166, for driving exhibitions at an unsanctioned race meeting held at San Fernando, California, on November 28, 1912, was definitely fixed to expire on May 28, 1913. E. E. Hewlett, of Los Angeles, manager of Tetzlaff and owner of the Fiat car driven by him at such unsanctioned meeting, was rendered ineligible for participation in any event sanctioned by the A. A. A. for a like period.

The application for reinstatement to good standing of the Staver Carriage Company, of Chicago, manufacturers of Staver-Chicago cars, who were on October 21, 1912, disqualified and suspended to June 1, 1913, for violation of rule 75 of the contest rules in advertising the performance of the Staver-Chicago cars which participated in the Around-Lake-Michigan tour conducted as a Grade III Non-Stock run, as being the performance of Stock Cars was considered and denied.

Frank C. Hamlin, of Los Angeles, entrant and driver of the Franklin car which won the 1912 Los Angeles-to-Phoenix desert road race, was disqualified and suspended until April 1, 1913, for violation of rule 75 in advertising and winning Franklin as a regular stock car, when the race in question was conducted as a non-stock, free-for-all event.

To Arrange Jacksonville-Atlanta Run

ATLANTA, GA., Jan. 10—The Atlanta Automobile and Accessory Association, at its meeting Thursday, appointed a committee to co-operate with a similar committee of the Jacksonville Automobile Club in promoting a run from Jacksonville to Atlanta in April. Some time during that month there will be a week of Metropolitan Grand Opera Company productions in the Gate City and the run will be held at a time when the tourists can attend these affairs.

Chicago Club Plans Novel Reliability

CHICAGO, ILL., Jan. 13—The Chicago Automobile Club, encouraged because of the success of the 1912 Elgin road races, which it promoted in conjunction with the Elgin Automobile Road Race Association, has determined to venture into the promotion of other motor contests. Announcement was made today that the C. A. C. would stage one of the most novel reliability runs ever attempted—a non-motor stop, night-and-day trip from Chicago to Boston by way of New York City. This will be run the last week in June and it is figured that the trip can be made in 3 1-2 days.

As roughly outlined now, it will be a non-stock event run under grade 3 of the A. A. A. rules, but maybe a stock car division will be added if enough entries are forthcoming. There will be a change of drivers and observers both morning and night, and it will be necessary to secure a special train to follow the tour to carry the relief crews and the officials. The rules will require that the motors be kept running continuously, even when taking on fuel and water, in order to escape penalization. It has been suggested that the entry fee be placed at $200, which would give the entrant the choice of starting one, two or three cars.

Co-operation with other clubs along the route will be sought. The Bay State Automobile Association already has proffered its services and it is thought Buffalo, Cleveland, New York and other big cities will do likewise.

CHICAGO, ILL., Jan. 13—*Special Telegram*—Dates selected for the reliability are June 25 to 28. The tentative schedule calls for controls at Toledo, Erie, Rochester, Albany, New York City and Boston. The distance is 1,276 miles and it is estimated that it will require 67,967 hours to make the journey.

Eighteen Cars Entered in Grand Prix

PARIS, Jan. 3—On the last day of the old year the entry list at ordinary fees closed for the French Grand Prix race to be run near Amiens early next July. The list contained eighteen cars, and unless manufacturers decide to pay double fees at the rate of $1,600 per car, this number of competitors will start in the classic. The low number comes as a surprise, but is due to the high entry fee charged, the ordinary rate of $800 per car having kept several out, and also to the peculiar difficulties of building cars to compete under limited fuel rules.

The entrants are, for France, three Peugeots, three Th. Schneiders and two DeLage; for England, four Sunbeams; for Germany, one Mathis and one Opel; for Italy, three rotary-valve Italas; for Belgium, one Excelsior.

A curious incident has arisen in connection with the Mercedes entry. Last September the Belgian agent for the Mercedes car sent a check to cover the entry of three cars. This was refused, for the rules state that all entries must be made by manufacturers. Just before the final closing a second check was sent by the Mercedes agent in Belgium, and also by the English agent, acting through the Royal Automobile Club. They were both refused, according to the rules, but it was believed that the agents would induce the factory to make the entry for them. This they have evidently been unable to do, for no direct entry has been sent. The Belgian agent has ordered a set of special cars from the Mercedes factory, but has evidently overlooked the fact that he would not be allowed to enter them himself.

Indiana Tour to Start July 1

INDIANAPOLIS, IND., Jan. 6—Eight o'clock on the evening of July 1 Indiana's great automobile tour to the Pacific Coast will leave this city. So definitely are the preparations being made that even the time of the departure can be announced.

At its recent meeting the Indiana Automobile Manufacturers' Association adopted the plans proposed for the big journey from the Hoosier capital to either San Francisco or Los Angeles. It will be a pathfinding expedition for the great rock road which some day will extend from the Atlantic to the Pacific Oceans, and for hundreds of tourists who yearly travel across the continent. Not only did they heartily approve of the general route and the details, but they also supported this by the definite promise of the entry of twenty-six cars.

Minor Shows Throughout the Country

All Milwaukee Dealers Join in Show for the First Time—Automobiles To Be Shown at Panama-Pacific Exposition Attendance at Montreal Over 35,000—Business $300,000

MILWAUKEE, WIS., Jan. 13—The striking feature of the fifth annual Milwaukee motor show, which opened in the Auditorium on Saturday evening, January 11, and closes Friday evening, January 17, is that for the first time since motor expositions were started in Milwaukee, every local dealer is represented by an exhibit.

Not being included in the national show circuit fostered by the manufacturers' organizations, Milwaukee was obliged to do a lot of tall hustling to make its show a success as compared with the expositions of nearby cities, notably Minneapolis, Kansas City, Denver, Indianapolis, Detroit and Cleveland, but it has done so.

There are represented in the show seventy-one distinct makes of pleasure cars, with an aggregate of 169 models on display; seven makes of electric cars, with twenty-three models on display; fourteen distinct makes of commercial vehicles, with forty-seven models on display, and twenty-seven distributors of supplies, accessories and parts, representing more than 500 factories.

From these figures it will be seen that Milwaukee could have done no better, and probably not as well, had it been included in the national show circuit.

Milwaukee dealers have fared well with their factories in being able to present cut-out chasses, polished chasses, and other novelties in stripped or finished cars which make a show more interesting than otherwise. In this connection it may be said that the cut-out chassis of the Hickman-Lauson-Diener Co., state agent for the Ford, is one of the most elaborate and instructive exhibits in the show.

It is also worthy of note that in addition to exhibits from every dealer in Milwaukee, outside factory representatives, factories or large distributors whose cars are not represented in Milwaukee by direct agents are showing products. Among these are the Peerless, Cole, Pathfinder and Enger. Cars which gained representation in Milwaukee since the last show in January, 1912, and now in the Milwaukee show for the first time include: Cartercar, Staver, Little, Chevrolet, Marathon, McFarlan 6, Stanley, Pullman, Nyberg, Davis Flyer, Metz, Premier, Stevens-Duryea and Velie.

There are meetings during the week of the Wisconsin Retail Automobile Dealers' Association, the Wisconsin Association of State Agents, the Wisconsin State Automobile Association, the organization of owners; the Wisconsin Commercial Car Association, the Wisconsin Accessories Association, and a half dozen lesser organizations which have to do with the sale and use of motor cars, parts, etc.

Automobiles for 1915 Panama Show

America may have in 1915 at the Panama-Pacific exposition to be held in San Francisco one of the greatest automobile exhibitions in its history. Negotiations are now under way looking to the erection of a separate building to house a motor exhibit to continue from the opening until the closing of the exposition. Capt. Baker of the exposition took up the matter of such a building with not a few of the automobile manufacturers nearly 1 year ago and since then the work of bringing the exposition authorities and the car makers together has continued.

Only this week the National Association of Automobile Manufacturers received word from San Francisco stating that the exposition company will erect a special building affording 210,000 square feet of exhibit space, and devoted exclusively to automobiles, motorcycles and accessories. The building will be a one-story structure 600 feet long and 350 feet wide.

So far the proposal has not been definitely accepted by the motorists, but it is being referred to the individual concerns and it is expected that no difficulties will be encountered. The discussed plan, in case of the acceptance of the proposal, is to handle the exhibit space similarly to the national shows. Foreign manufacturers will receive the same opportunities to exhibit as American builders.

The completion and occupancy of this automobile palace will mark the beginning of a new era so far as motor exhibits at great expositions are concerned, in that it will be the first time at which a separate building will be devoted to the automobile, the motorcycle and accessories.

Montreal Show a Great Success

MONTREAL, QUE., Jan. 11—With a wild tooting of horns and shrieks of sirens the seventh annual automobile show at the Drill Shed and Sixty-fifth Armory closed on Saturday night.

In point of the numbers of exhibits, the attendance and the business done, the show just closed showed a great advance on those of previous years. It is estimated that between 35,000 and 40,000 people attended the two shows, and the actual sales reported by dealers amount to $300,000. Not that these figures comprise all the sales made, for some of the firms approached reported that it was against their business policy to either report the sales made or label the cars sold. Privately they admitted that business and the prospects for the future could not have been better, and from $500,000 to $750,000 roughly estimates the business done. With the sales to dealers at outside points from samples shown in the show the estimate is over $1,000,000 mark.

Columbus Show Is Drawing Near

COLUMBUS, O., Jan. 11—The organization of the Columbus Auto Trades Association was completed recently when a constitution and by-laws were adopted. More than fifty dealers attended and much enthusiasm was shown in the affairs of the association. The constitution is modeled after those governing the chapters founded in many of the Eastern cities. Plans for the automobile show were discussed. The new association will co-operate with the automobile club in giving the show.

WASHINGTON, D. C., Jan. 11—A new motor organization, to be known as the Washington Motorists' Association, is being formed to take the place of the Automobile Club of Washington, which was disbanded several weeks ago. A committee from the old club, with W. C. Duvall as chairman, has drawn up a tentative constitution and by-laws.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Problems To Solve

THE progress of the first few days of the dual automobile show, running this week at Grand Central Palace and Madison Square Garden, one of the greatest in the history of the industry so far as numbers of exhibits is concerned, is marked by an undercurrent of unrest with a majority of the makers, due in not a few cases to the cranking motor avalanche, to the wire wheel wave and also to the electric lighting movement.

Of these three the motor starting movement, or, as it has been designated by many, the cranking motor movement, occupies premier place. The uncertainty connected with it is not in every case confined to the automobile maker but often to the maker of the cranking apparatus. This is but natural as the movement has precipitated itself with such hurricane speed that there are some makers of cranking motors who marketed a product and scarcely had it installed on test cars for more than a week when it was found inadequate and new designs were immediately pushed through. **There is scarcely a manufacturer of electric cranking motors who is not already busy on improvements.** In fact the automobile maker is demanding something definite for his 1914 models to which he is at present looking forward. The next 4 months will witness unparalleled activity in the cranking motor field. A few are now well settled on their types.

A visitor at the show can glean in a cursory round of the exhibit spaces the unpreparedness of many car makers for the electric cranking motor. The different apparatuses are installed wherever there was available space and not where they enter into the general layout of the car to the best advantage. **As a result some of the chassis are cluttered up worse than they have been since the days of the introduction of the magneto.** As it is with many today, the installment of the cranking motor began and ended in the assembly room, whereas it should begin in the pattern shop. There are a few makers who realized well in advance that they were going to fit a certain make of cranking motor and generator to furnish electric current for lighting and cranking, and they made provision in the crankcase for such parts, but their numbers are small when compared with those who solved the problem, if the word may be used, in the assembly department.

Before another year this will all be changed, and it is a realization of this that is spurring the car builder to push the makers of cranking motors to their utmost activity. There are some exhibitors who refused to list cranking motors as equipment before the opening of the shows and have since been forced by the pressure of agents to add them. This in itself shows the country-wide influence of the movement and the strength of it. **It would seem that the buying public is asking more about cranking motors than about merit in motor and chassis design, or materials used or workmanship bestowed on these materials.** It will be impossible for the makers of cranking motors to supply the demand of the next few months and an equally difficult task with many of them to get their 1914 types ready in time.

The wire wheel movement has taken hold in real earnest. This wheel is here to stay. Its advent is creating not a few far-reaching problems. Some want to continue with the demountable rim, but the advocates of the wire wheel argue that the use of the demountable rim will rob the wheel of one of its leading merits, namely, the light peripheral weight with the consequent increase of flexibility in the car. It is expected that the final solution of this problem will largely rest with the action of the Society of Automobile Engineers, which has recently created a new division of the standard committee to handle this subject. There are few, if any, exceptions taken to the wire wheel because of the difference in appearance, when compared with the wood type. The general publicity of the wire type has reached nearly every city in the country and has paved the way for a general acceptance of it when the time comes that supply will equal demand and prices will be finally adjusted. The merit of the wire wheel in conducting heat out of the tire, and so increasing its life, is commented upon very generally.

Electric lighting has made nearly a clean sweep of the field and today it is only a question of adaptation of the desired generator to the motor and installing the lamp equipment. In this respect there are a few novelties along the line of coupling the headlights and dashlights in one, and another innovation in using a single headlight and incorporating it in the radiator. Incorporating dashlights in the baseboard of the windshield is becoming more general, and it is in this respect that the superiority of the electric bulb as a lighting source appears to advantage, as the entire outfit can be nested in the thickness of a standard windshield baseboard. Makers of pressed metal bodies with the cowl dash are incorporating miniature hooded portions for the lights.

There has not been the anticipated progress in body lines, although in such matters as improved upholstery and a little added room there has been a very pronounced advance. With a great majority of the makers, the general lines of last year are continued. The blending of hood and body has not been carried to the anticipated extent, although many use cowled dashes, yet few of them have altered the hood lines or the body lines to conform with these.

On closed cars the pronounced downward curve of the roof over the driver's seat imparts an air of smartness that is generally commented upon, and another year will witness many modifications of it. A few makers are building limousine bodies lower than last year and some are so low that the passengers' hats will be endangered if rough roads are encountered. One or two makers are showing concealed door hinges and more are talking about fitting them for another year. The die-made sheet metal body is being used by not a few. It is a clean-cut job with the various stampings welded into one piece, not a seam showing. Such bodies are expensive except when made in large quantities as the necessary dies for a certain design will cost between $10,000 and $20,000. Many more of these bodies will be used this season and there are evidences of a general movement in favor of them.

Automobile Chamber of Commerce Formed

AT the annual meeting of the Automobile Board of Trade held January 14, the fifty-one members present unanimously voted in favor of amalgamation with the National Association of Automobile Manufacturers under the new name of the Automobile Chamber of Commerce. As the executive committee and a majority of the members of the N. A. A. M. have also voted favorably it is but a matter of form until the amalgamation takes place and the time-honored name, National Association of Automobile Manufacturers, becomes a matter of history, and with it will go the more recent organization, the Automobile Board of Trade, which came into being after the decision against the Selden patent 2 years ago, which brought about the end of the licensed association and out of which came the Automobile Board of Trade, as it is known to the industry at the present time.

The new Automobile Chamber of Commerce will be joyously hailed by all, as it means the end of the dual organizations which have been practically covering the same field. For example, the N. A. A. M. has at present 105 members and the Board of Trade has sixty-five, and of these sixty-five all excepting one are also members of the N. A. A. M. Amalgamating the two will mean the end of two separate committees on legislation, two separate committees on roads, etc., etc. Amalgamation means a 50 per cent. simplicity in the management of the industry.

There yet remains much to be done before the final act will be accomplished and the dissolution of the two present organizations accomplished. Each organization will get the unanimous approval of its entire membership roster. A charter will then be applied for the Automobile Chamber of Commerce and a general meeting of the membership of both organizations called, at which meeting the organization of the new body will take place. It is expected that the articles of incorporation will be practically identical with those of the present Board of Trade. When the Chamber of Commerce is formed all of the present membership of the two organizations will be permitted to join and the open-door policy will be extended to outside manufacturers.

The Automobile Chamber of Commerce will undoubtedly take over the present assets of both existing organizations and the work of them will be carried on under the new management. These will include shows, legal, patents, good roads work, statistical, etc.

At the meeting the Automobile Board of Trade reelected its officers of the past year, namely: Charles Clifton, president; C. C. Hanch, vicepresident; R. D. Chapin, secretary; George Pope, treasurer; H. A. Bonnell, general manager, and the following directors: Hugh Chalmes, John N. Willys, S. D. Waldon, W. C. Leland and S. T. Davis, Jr.

C. GORDON REEL, the New York State Superintendent of Highways, has submitted to the State Legislature the annual report on highway construction, maintenance and improvements, from which the following is an extract:

The status of highway improvement to date in the State of New York is as follows:

	Miles
State highways and county highways now improved	3,578
State highways and county highways now under contract	1,627
Expedited routes not contracted for but the construction of which was contemplated in the expediting bills of 1910-11	298
Remaining state highway and county highway to be improved	6,483
Total	11,986

Of the town highways to date there have been macadamized	3,514
Improved as gravel roads	8,500
Shaped, crowned and standardized as to width	50,000
Put in safe condition for travel	6,000
Total	68,014

Total mileage of public roads in the State of New York, 80,000 miles.

All of the original $50,000,000 bond issue has been appropriated and is accounted for as follows:

Original authorized bond issue highway improvement fund	$50,000,000.00
Expended appropriations to January 1, 1912	22,188,593.56
Balance unexpended January 1, 1912	$27,811,406.44
Expended for all purposes from highway improvement fund to December 1, 1912	8,073,157.58
Remaining from previous appropriations unexpended December 1, 1912	$19,738,248.86
Appropriation, chapter 247, Laws of 1912, available October 1, 1912	1,045,000.00
Balance unexpended, salary appropriations reverting to highway improvement fund October 1, 1912	27,372.24
Comptroller's balance, highway improvement fund, December 1, 1912	$20,810,621.10

Obligation

Balance due on contracts not expedited December 1, 1912	$8,455,810.58
Elimination of grade crossings ordered to date	199,733.49
Balance original bond issue not obligated December 1, 1912	284,518.03
Balance due on contracts for expedited routes December 1, 1912	9,447,546.91
Balance available for expedited routes not under contract December 1, 1912	2,422,972.09
	$20,810,621.10

During the calendar year there has been placed under contract 1,003 miles of State highway and 517 miles of county highway, and there has been completed a total of 662 miles.

Standards Committee of the S. A. E. Meets

Tentatively Adopts Report of the New Division on Motor Testing Which Presages Standardization of Methods for Testing Automobile Engines

THE Standards Committee of the Society of Automobile Engineers held a meeting at the headquarters of the Society, Wednesday, at which the various division reports were submitted to the committee as a whole and passed to the Society for consideration later in the week according to the program. Chairman Henry Souther called the meeting to order at 10.30 a. m.

The report of the Aluminum and Copper Alloys Division was the first to be read by the chairman, Wm. H. Barr, whose communication was short. Two alloys were recommended by the division for addition to the list already listed by the Society as standard. These are two bronzes, the first of which is intended for valves, light gears and the like. The composition follows:

Copper	87 to 89	per cent.
Tin	9.5 to 10.5	per cent.
Manganese	1.5 to 2.5	per cent.

The other alloy submitted by the Division was for a gear bronze, which is similar to the English gear bronze and it is recommended for its quiet running. Its composition is given:

Copper	88 to 89	per cent.
Tin	11 to 12	per cent.
Phosphorus	0.15 to 0.30	per cent.

Report of the Broaches Division

In speaking of the work of this division, Chairman Souther stated that its work is progressing just as it should. His only criticism of the report was as to the close limits set for the amount of copper in the gear bronze, namely the restricting of the limits between 88 and 89 per cent. He questioned the advisability of fixing such close limits if there were any possibility of such restriction affecting the manufacturing cost of the alloy. However, members of the division assured the chairman that such close limits of apportionment would not be very difficult of attainment and that they would not cause any rise in the commercial market price of the alloy. The report was then accepted and its submission to the Society directed.

Chairman C. W. Spicer, of the Broaches Division, submitted a short report of the work of his committee since the last session of the society. It is essentially a report of progress, he said and while the division has no new data to proposed at this meeting of the society, nevertheless there are a number of special considerations to be brought up. The hobbing of splined shafts was touched upon and the machining of these shafts in this way was characterized as a step forward in their manufacture.

There was no discussion of the Broaches Division report, Mr. Souther stating that the manufacture of broaches is still in the process of evolution and that any more definite report by the Broaches Division at this time would not be advisable on this account. It was, therefore, passed to the society as read.

A new division on Motor Testing was created at the last summer meeting of the society with J. O. Heinze as its chairman. While in operation only 3 months the activities of the division have been very marked and Mr. Heinze spoke very interestingly of what has been done. A number of diagrams were submitted showing installations of apparatus as used at the Northway plant in Detroit by Mr. Heinze for the determination of various data in connection with motors.

Although Mr. Heinze stated that the work of his committee has not progressed rapidly enough to make his report a basis for motor testing, a very clear and comprehensive foundation has been laid for a line of standardization of motor testing which will be of undoubted benefit to every member of the society interested in motor manufacture and testing. The division is endeavoring to fix upon and develop those tests which should prove of greatest practical value rather than striving for scientific accuracy. Several questions were submitted by Mr. Heinze in order to determine the policy of the division. Should the division specify just what procedure should be followed in making a test as to the arrangement of the apparatus and the sizes of the dynamometers and other instruments or should these points be left to the engineer making the tests? Should certain testing instruments be made standard by the division? Should the division fix upon what tests are important and direct their use? Should there be standard curve and data sheets printed by the society and distributed to members so that comparative results could be determined?

In fact Mr. Heinze stated that the whole matter is yet up for discussion and he solicited the fullest criticism and suggestion from the members as a whole. In order for the division to arrive at any conclusive and definite results for the approval of the society it must have more time for its work. Three months is a short period for any concrete ideas.

A sample curve and data sheet which was drawn up by Mr. Heinze was submitted. On this sheet it was proposed to include the specific gravity of the fuel, various necessary temperatures, barometric reading, the kind and size of motor under test, the type of dynamometer used, the carbureter and the magneto makes. Below spaces for this data the curves were drawn. In connection with the sample curves shown, it was brought out that it is a question as to what curves are of sufficient importance to be plotted. Should only the indicated horsepower curve be submitted or should curves of volumetric efficiency, air consumption of the motor with and without the carbureter, torque, gasoline consumption and the like be added. It is a question as to just what points would be of greatest assistance to the society at large.

The several charts showing suggested arrangements of apparatus were next touched upon by Mr. Heinze and while in each case the layout depicted only one arrangement for the determination of any one factor, there are of course a number of other arrangements which would probably work equally as well. Those shown in each case embodied the schemes employed at the Northway plant and are the ideas of Mr. Heinze. One cut showed the method of arriving at air and gasoline consumption; another for accurately fixing the timing. In his tests of this nature Mr. Heinze eliminates the primary timing and works upon the secondary spark in an effort to dispose of the errors of secondary spark ignition. It is advisable not only to determine the position of the secondary spark but also to arrive at the heat units of the spark and for that purpose another proposed method of determination was submitted. It is also necessary to measure the vibration of motors. All have a critical speed at which they have their greatest period of vibration and this should also be determined. An arrangement of apparatus by which the engine under test is mounted upon a set of springs and its vibration amplitude at various speeds determined was next shown. Another proposed test is in order to measure the acceleration of carbureters. Some instruments accelerate better and more steadily than others and it is important for the engineer to be able to determine that device best fitted to the engine which he manufactures. The proposed arrangement for such determination was pointed out to consist essentially of a drum rotated by a descending weight and so connected as to gradually open the carbureter throttle as the weight lowers. Cylinder compression should be measured also, and further, manograph curves should be obtained. As scheme of obtaining such curves was shown in which the standard reflecting type was somewhat modified so as to eliminate the objectionable feature, i.e., the long air pipe.

A scheme of test was also illustrated by means of which the radiator maker could design his product for certain size motors with acccuracy.

Sheet Metal Division's Work

T. V. Buckwalter, chairman of the Sheet Metals Division, next presented the report of his committee. The work divides itself into two heads, he said. The first of these comprises the submission of specifications for sheet metal materials while the second refers to the specifications for dimensions for these materials. He advocated the standardization of gauges. It is first necessary to know what sizes of sheets and rods are used by the manufacturers before it is possible to arrive at what standards to recommend. For this purpose sheets have been prepared by the division to be sent to the various members of the society on which they are requested to signify these sizes. It is hoped that the returns on this matter will be complete enough at the time of the summer meeting so that a concrete report may be submitted then. Specifications for manganese bronze were submitted by the division as follows:

Copper	56 to 60 per cent.
Tin	0.50 to 1.50 per cent.
Iron	0.50 to 1.50 per cent.
Manganese	0 to 0.75 per cent.
Lead impurities	Not to exceed 0.25 per cent.
Zinc	Remainder.

In thus submitting the formula for this metal, the committee has endeavored to tie the specifications down to chemical combinations rather than to chemical and physical combinations, according to Mr. Buckwalter.

There was some difference of opinion as to whether this specification belonged rightfully in the reports of the Sheet Metals Division or whether it should be included in the list of alloys standardized by the Alloys Division. Inasmuch as it is not intended to be a formula for cast bronze, W. R. Webster stated that it should stay where it was. The question was merely one of reference. The engineer would naturally look under alloys for this composition, Mr. Souther thought. He finally proposed that the specification be listed in both places, which cleared the discussion and allowed the report to be passed to the society.

The work of the Truck Standards Division since the last session was next gone over by its chairman, W. P. Kennedy. The report this time was not very extensive for the reason that returns from all the manufacturers on the questions asked have not been received, although the blanks sent out have been replied to by the majority of the large manufacturers. As was pointed out at last summer's meeting and again emphasized by Mr. Kennedy on Wednesday, the information requested of the truck makers is not for publication but is required for use in determining the standards. Although unprepared to present definite standards on any parts as yet, it is the sense of the committee that it should proceed slowly to fix a number of the more important points such as the size of motors in relation to load carrying capacities and the tire sizes for different loads and capacities. If five or six such main points are determined, the division will have gone as far as it can proceed as a first step. The report was referred to the society.

Mr. Kennedy is also chairman of the Wheel Dimensions and Fastenings for Tires Division, the report of which he next presented. This is the fourth report of this division, the work of which has been characterized as the masterpiece of the society. The report of this division follows:

S. A. E. Standard Motor Truck Wheel

Edges of Permanent Metal Felloe Band

"We recommend that the permanent metal felloe band be rounded on the two outside edges with the radius not to exceed 1-16 inch, and that one inside edge of the band have an angle of about 45 degrees, extending about 1-16 inch from the edge.

Tolerance in Width of Permanent Metal Felloe Band

"We further recommend that the previous recommendation as to tolerance in width of permanent metal felloe band be modified to read as follows:

	Plus	Minus
Tolerance in width	1-64 inch	1-64 inch

"And, in consequence of the last mentioned above recommendation, that the previous recommendation as to trueness of band when placed on surface plate be modified to read as follows:

Either side of the band when laid on a surface plate must not clear more than 1-64 inch at any point.

Tolerence in Circumference of Permanent Metal Felloe Band

In June, 1911, the Division voted that the tolerance in circumference should be:

	Plus	Minus
Before application to wheel	1-16"	0
After application to wheel	1-8"	0

In February, 1912, the Division, in view of the then more extensive manufacture of rigid-base tires, recommended that the circumferential tolerance should be:

	Plus	Minus
Before application to wheel	1-32"	1-32"
After application to wheel	1-16"	1-32"

Both of these recommendations were accepted by the Society, the latter, of course, superseding the former.

In this connection the point has been made by wheel manufacturers that if the 1-32" plus tolerance be taken up in the manufacture of the band, the wheel manufacturer has left to him only one-half or 1-32" of his 1-16" plus tolerance in the application of the band to the wheel.

The first view of the Committee at its meeting of November 13, 1912, was that no change in circumferential tolerance should be recommended until a greater demand for such change should be evident. After a long discussion, however, upon notice, duly seconded, it was

Voted that the last mentioned above tolerance in circumference of permanent metal felloe band should be modified to read:

	Plus	Minus
Before application to wheel	0	1-16"
After application to wheel	1-16"	1-32"

Measuring Circumference of Bands

In measuring circumference of the band, if there is no allowance on the tapeline itself, a correction amounting to three times the thickness of the tapeline should be made.

A rather prolonged discussion of this paper was held. Bert Morley, of Kelsey Wheel Company, stated that his concern has held close to the S. A. E. recommended limits since last fall. He brought up the advisability of machining bands of 6 inches or under and recommended that this not be done. F. H. Moyer, of the Firestone company, was particularly opposed to this machining although he stated that the Firestone company has had no trouble in adhering to the dimensions adopted as the result of the division's recommendations. While he stated that it is perfectly possible to machine the bands, it certainly adds to the cost of production and questioned if the increased cost is compatible with the benefits derived from the requirement. O. W. Mott, of the Jackson Rim Company, is also opposed to machining bands unless absolutely necessary, although he stated that it could be done, of course, at somewhat extra cost. Is such accuracy necessary and does it pay in the increased life of the tire, was asked. Mr. Kennedy stated that this requirement had been recommended only after urgent pressure had been brought to bear by the majority of the tire people. Although not unanimously in favor of it, he said that his committee had to be governed by the desires of the majority. Inasmuch as there was such a difference of opinion on this point he suggested that its adoption be suspended until the summer meeting.

Chairman Souther then took up the internal strife at present existing among the members of the United Rim Association and pointed out that this organization is soon to be disrupted with the result that the market will be flooded with many types of rims. There are at present about five types of quick detachables and as many demountables. With this situation in view it is now the psychological moment for the society to step in and standardize this product. Accordingly he proposed the formation of a committee to deal with the subject which would be so constituted as to be unbiased in its views. It was finally voted by the standards committee to recommend to the council the widening of the scope of the recently formed Wire Wheels Division so as to deal with the situation. It was suggested that the name of this division be changed from wire wheels to Pleasure Wheel Division.

Of particular interest at this time was the report of the Division on Lamp Standards by Chairman Palmer. The relative advantages of the grounded and ungrounded returns for lighting systems commanded attention on account of the rapid development in electric lighting recently. It was brought out that the grounded return provides bigger contact points and better insulation of the lamp receptacles. Further with grounded returns there are fewer connections at the switch; that an ordinary system involving head, side and tail lamps has eleven connections with the grounded as against fourteen with the ungrounded system.

As to the advantages of the ungrounded return they all hinge on the fact that accidental grounds on the battery side of a grounded return system short-circuits the current and damages the battery; whereas in the ungrounded return system it would be necessary to ground both sides of the circuit simultaneously. With grounded systems horns and other dash electric devices must be carefully insulated from the metal parts of the body. No definite recommendation was made on this point.

This report recommended that standard electric light bulbs be known as 7-volt bulbs and have an efficiency of 1.1 watts per candle at voltages between 6.5 and 7 volts. Standard electric headlights are to be 2 1-16 inches diameter size and capable of being focused in a reflector of 7-8 inches or greater focal length. An effort is being made to get data from battery makers from which to specify standard dimensions of batteries and plates, giving three standard plate sizes from which batteries of any capacity can be made by increasing the overall battery length.

Chairman Riker of the Miscellaneous Division mentioned work on method of designating gear ratios. His report dealt chiefly with yoke and rod end sections.

The use of low grade fuel for motor trucks was discussed by N. B. Polk, who considered different types of fuel such as kerosene, distillate and naphtha as substitutes for gasoline and suggested the requirements of carbureter for the purpose and also gave some hints on overcoming the difficulties of hard starting. Mr. Polk's paper precipitated a lively discussion on engine fuels and particularly the change in the grade of gasoline during the past few years. As an outcome it is probable that a committee will be appointed to seriously consider the gasoline problem and its effect on the industry as a whole.

Paper on Brakes Read at Indiana S. A. E.

INDIANAPOLIS, IND., Jan. 13—A paper on the subject of Brakes was read by Professor C. B. Veal, of Purdue University, Lafayette, at a meeting of the Indiana Section of the Society of Automobile Engineers, held at the Claypool Hotel in this city last Tuesday night.

Professor Veal is identified with the mechanical engineering department and testing department at the university and is recognized as one of the most able experts in engineering matters in the state. His views on the subject of brakes were therefore received with considerable interest. Professor Veal urged the necessity of applying the standard practice to brake construction and complimented Indiana manufacturers highly.

Packard Has Big Year

Gross Earnings for Current Year Were $3,412,862.05—Firm's Gross Sales Have Increased to $14,613,057.27

Capital Stock of Packard Company Is $10,000,000 which Is Equally Divided Between Common and Preferred

DETROIT, MICH.—In a report just issued by Henry B. Joy, president of the Packard Motor Car Company to the directors of the company for the fiscal year ending August 31, 1912, it is shown that the concern's gross sales including commercial vehicles have increased from $11,624,588.37 in the previous year to $14,613,057.27 in the year covered by the report. The gross earnings for the current year were $3,412,862.05. Deducting from this the depreciation of buildings, machinery, tools and development leaves net earnings for the year of $2,182,376.20. Subtracting the dividends upon the preferred stock, which amounted to $350,000, the net surplus for the current year is $1,832,376.20, which amount swells the total surplus (considering that which was on hand at the beginning of the fiscal year) to $4,816,398.01. From this total the Board of Directors has authorized deductions to reduce the amount at which "rights, privileges, franchises, etc.," be carried on the books from $3,274,958.89 to $1.00 and to adjust the books to the inventory taken December 31, 1911, by the charging off of $342,656.30, leaving a final net surplus on August 31 last of $1,198,783.82.

The capital stock of the Packard company is $10,000,000 which is equally divided between common and preferred. In the general balance sheet, the resources include real estate valued at cost at $285,312.49, buildings at $2,084,865.81, machinery at $1,145,381.22, and material stock, consisting of raw materials, that in process of construction and finished vehicles, of $5,351,217.23. In the above items depreciation has been deducted from buildings and machinery.

In submitting the report, Mr. Joy points out that wages have constantly increased during the year and that they are higher than ever before, they being higher in Detroit than in other cities investigated. The increased volume of Packard business is shown to be made possible by the new scheme of manufacture now in force. The former endeavor was to bring out of the engineering department two models of chassis of two sizes at the same time to be turned over to the manufacturing department simultaneously in order to have them ready for the market at the same time, both models thus going along together through the factory. This has proven impracticable for many reasons, and causes delayed deliveries and restricted output. Under the present scheme, one model of chassis is developed and manufacturd at a time and offered to the market when ready. Thus the Packard "38" came on the market this fall and winter, and the "48" will be submitted to the trade next spring and summer.

No dividends on the Packard common stock have been paid for the last 3 years, all earnings in excess of the preferred stock dividends going into the capital account. Mr. Joy states that he feels confident the current year will see a resumption of payments of a small dividend rate on the common stock, although the largest share of the earnings must, however, be added to the working capital to meet added requirements of increased volume of business.

—

The Indiana Automobile Manufacturers' Association, which journeyed from the Hoosier capital eighty-five strong in a special train to the shows, held a shore dinner Sunday afternoon at Coney Island which over 100 attended. The occasion was exceedingly enjoyable, according to the diners.

Automobile Securities Quotations

Tendencies in the automobile stock market were slightly upward this week, with few exceptions. Consolidated common was a feature, scoring a ten-point advance over last week; Peerless and Swinehart advanced likewise, and the same holds good of International Motor common and Chalmers. Alco common and Goodrich common fell off slightly. Generally speaking, the tone of trading was firm and the volume of transactions fair. Willys-Overland stock was strong and advanced slightly during the week. The table follows:

Weed Patents Again Upheld

Preliminary Injunction Granted

CHICAGO, ILL., Jan. 11—Again affirming the validity of the Parsons chain-grip patents, under which the Weed Chain Tire Grip Company is the sole licensee, the United States Circuit Court last Tuesday upheld the claims of the Weed interests in the appeal by the H. Channon Company from the District Court. A preliminary injunction was granted as a result of the original hearing before Judge A. L. Sanborn on April 25. The appeal hearing was granted for the October session of the October term of the United States Circuit Court of Appeals, Judges Baker, Seaman and Kohlsaat sitting. In the decision handed down by Judge Baker the following evidence was considered: That the Parsons patent, No. 723,299, relates to an anti-skidding means held across the tire by two rings, of smaller diameter than the tire, but held so loosely that the anti-skidding means may travel circumferentially around the tire, and thus not injure the tire, as would anti-skidding means held rigidly on the tire. The appellants held that, whereas the Channon device employed a means of attaching the side-rings securely to the tire, so that the anti-skidding means would not creep on the tire, and it was sold with instructions that it be so used, it was not an infringement on the Weed device.

The court ruled, however, that, whereas the device manufactured by the Channon company was identical with the Weed device, except in this particular, the securing means was a cover and a sham, and that as the creeping ability of the original device was desirable, the user could innocently remove the securing means to protect the tire; and that, therefore, the Channon device was an infringement.

Market Changes for the Week

The feature of interest in tin in the domestic market yesterday was the advance of $.25 per hundred pounds, the holders of supplies taking advantage of light stocks and the consumers' needs to force the rise. Bessemer steel and open-hearth steel each experienced a rise of $1.00 on Thursday, due to good trading conditions. The copper market was demoralized yesterday with speculators operating feverishly in standard warrants and both domestic and foreign consumers remaining out of the market temporarily. Copper electric suffered a loss of $.00 7-8 per pound and copper Lake $.00 3-4. Lead was dull but steady, remaining at $4.30 per hundred pounds throughout the week. Linseed oil and cottonseed oil experienced change in prices, linseed oil a gain of $.01 and cottonseed oil a loss of $.10.

Now Maxwell Motor Co., Inc.

New Company Takes Over U. S. M.

On Thursday, January 9, Judge Hough, of the United States District Court for the Southern District of the State of New York, ordered the sale of the assets and good will of the United States Motor Company and its subsidiaries to the reorganization committee under condition that the committee agree to pay all unpaid expenses and obligations incurred by the receivers in the administration of the properties, all compensation to receivers and ancillary receivers and their attorneys, and the following percentages on all claims as finally adjudged against the following companies: United States Motor Company, 32.5 per cent.; Alden-Sampson Company, 24 per cent.; Brush Runabout Company, 33 per cent.; Columbia Company, 91 per cent.; Dayton Company, 39 per cent.; Maxwell-Briscoe Company, 60 per cent.

The Standard Motor Company was incorporated January 11 under the laws of Delaware, with a capital of $31,000,000 to take over the property and business of the United States Motor Company. As the name of this organization was found to conflict with the names of other companies, the name was changed on Monday, January 13, to the Maxwell Motor Company, Inc. The Delaware incorporation stands.

Judge Hough signed the order transferring the property of the United States Motor Company to the new company on Saturday. The transfer of the property was effected on Monday. The legal representatives of the new organization state that at the present time 98 per cent. of the company's indebtedness is paid up. They predict that the company's affairs will probably be in a more or less settled condition by February 15.

Empire Tire Busy Again

On January 2, $1.000,000 Worth of Stock Issued and Sold to Creditors —No Settlement of Liabilities

Turns Out 2400 Inner Tubes and 700 Casings a Day—Export Trade Amounts to 365,000 Tubes a Year

After it had been announced some time ago that the Empire Tire Company, Trenton, N. J., had been dissolved, it is now becoming known that this was not so. The company which, like the Empire Rubber Manufacturing Company of the same city, is practically controlled by General Edward Murray, was consolidated with the latter concern about December 1. At that time, the liabilities of the Empire Tire Company were $300,000 and the quick available assets $1,200,000, but the company suffered from a shortage of cash with which to carry on its business. It was on this account that on January 2 $1,000,000 worth of stock, half common and half preferred, was issued and sold, partly to the creditors, but was not offered to them as a settlement of the company's liabilities. These creditors, who were largely firms supplying the Empire Tire Company with raw materials, were invited to subscribe to 90 per cent. of the stock issue and the stock was sold at a little below par value.

With the ample capital now on hand, the Empire plant turns out 2400 inner tubes and 700 casings a day, according to the New York sales manager of the company. An increasing percentage of this output consists in red rubber tubes and casings. The export trade of the firm, which is given considerable attention, amounts to a very high portion of its total business, there being a total export of 365,000 tubes a year. In addition to continuing its former line of products the Empire company has begun to manufacture a non-skid tread casing, the projections of which are oblong and 3 inches in length, arranged longitudinally on the casing surface proper.

Keeton Company Buys Oliver Plant

Detroit, Mich., Jan. 14—The property at Breckenridge street, Lawton avenue and the Michigan Central tracks, formerly occupied by the Oliver Motor Truck Company, has been purchased by the Keeton Motor Car Company at a purchase price of $50,000. In the group of buildings are three of modern factory construction, 220 by 80 feet each, and one building 140 by 80 feet. A fifth building 110 by 80 feet will be added at once.

Streator's Personal Property Sold

Chicago, Ill., Jan. 15—*Special Telegram*—All the personal property of the Streator Motor Car Company, Streator, Ill., manufacturer of Halladay cars was sold yesterday at auction to the Merchants' Realization Company, of Chicago. The price paid was $56,000 which included all cars and those in the course of construction, together with the machinery contained in the plant. The sale is to be confirmed by the court sometime during the week of January 20 and in the event that the court should call the sale void the property will be reauctioned immediately. Also it is expected that the entire plant will be sold, including personal and real property. As yet no bids have been received for the latter but disposition will probably be made of it soon.

Swinehart Resigns—C. A. Swinehart has announced his resignation as sales manager of the Swinehart Tire & Rubber Company, to take effect February 1. Although his plans for the future have not been definitely decided upon, he will continue in the tire business.

Hartz Succeeds Hupp As R. C. H. President

Vice-Presidency Taken by Former President—Seider, Secretary—Board of Directors Elected

Dealers in Forty-Two Foreign Countries Ordered 1,200 Cars—Last Year Over 7,000 Cars Were Sold

DETROIT, MICH., Jan. 13—At the meeting of the R. C. H. Corporation, J. F. Hartz, of Detroit, became president and treasurer of the concern, succeeding R. C. Hupp, who was elected vice-president. C. P. Seider, formerly vice-president, is now secretary. The company at present has on its books orders from American dealers for 15,000 cars. Dealers in forty-two foreign countries have ordered 1,200 cars. Last year more than 7,000 R. C. H. cars were sold.

Mr. Hartz, the new president and treasurer, is very well known to the business interests of Detroit, being president of the J. P. Hartz Company, president of the C. M. Hall Lamp Company and vice-president of the Williams Brothers' Company.

Besides the officers the new board of directors of the R. C. H. Corporation comprises G. W. Rogers and J. G. Robertson, of Akron, O.; John Kelsey and Joseph H. Clark, of Detroit; G. Jahn, of New York, and C. C. McCutcheon, of Jackson, Mich. January 1 Peyton R. Janney, formerly of the General Motors staff, became general manager, retaining Fred R. Bump as assistant general manager.

Automobile Insurance Takes New Form

The Maryland Motor Car Insurance Company, Baltimore, Md., and New York City, which for some time has issued separate policies for liability, car loss, accidents and fire, has combined with the United States Fidelity & Guaranty Company, New York City, for the issue of a combination policy covering all these possibilities. While the rates are not influenced by this arrangement, it serves to simplify the handling of insurance for the broker as well as for the holder of a policy. Under the arrangement, the user of a policy has the option of separate insurance for any of the above subjects or of a joint policy. The separate insurance business is so being shared between the Maryland and the U. S. Fidelity company that the former specializes on fire insurance and the latter of liability.

Texas Increases Freight Charges

AUSTIN, TEX., Jan. 13—The State Railroad Commission has issued an order amending its circular relating to the transportation of baggage from passenger trains in this state, so as to provide that automobiles shall not be accepted as baggage in regular baggage cars, but they may be transported in extra baggage cars at additional compensation. A charge of 10 cents per mile for automobiles or other motor vehicles, with a minimum of $5 for each automobile, in addition to the regular charges for extra cars, is provided. The order will become effective January 20.

Aluminum Companies in Combine

WASHINGTON, D. C., Jan. 15—At a session of the House Committee on Ways and Means on January 14, President Arthur V. Davis, president of the Aluminum Company of America, admitted that his company, the only aluminum factory in the United States, owns the Canadian Aluminum Company, which in turn had agreements with each of the seven foreign aluminum companies. This agreement embraces the aluminum industry of the world, with the exception of the United States. This country is excepted, according to Mr. Davis, due to the Sherman anti-trust law.

President Davis testified that the total surplus of the company is $12,000,000 and that the company is capitalized at $30,000,000 on which dividends are being issued at 4 per cent. on the capital stock. During the past three years the concern has been earning annually from 15 to 17 per cent. It was brought out that of the $30,000,000 of capital, only $1,860,000 was actually paid in, the remainder representing earned profits. Davis protested against any reduction of the tariff on aluminum and denied that his company exported any of the metal.

$100,000 for Cheap Fuel

PARIS, Dec. 24—Seriously alarmed at the increasing cost of gasoline, the International Association of Recognized Automobile Clubs, at its meeting here, decided, on the proposal of René de Knyff, to offer a prize of $100,000 for the best alternative fuel for use in existing internal-combustion motors. The regulations of the competition have yet to be drawn up and will not be made public until a promise has been obtained from the governments of the interested countries that the new fuel will be either free from taxation or admitted at a very low fixed tax. The fuel must be available in big quantities, and must be of such a nature that it cannot be monopolized by trusts.

The countries represented at the conference were France, Great Britain, Germany, Austria, Belgium, Denmark, Holland, Hungary, Italy, Russia, Switzerland, Sweden, Egypt, Roumania and America. The American delegates were George Heath and William S. Hogan. The national clubs of these nations have agreed to raise the sum of $100,000 for the fuel prize.

Tone Corporation Seeking Factory

INDIANAPOLIS, IND., Jan. 13—The Tone Car Corporation, organized in Indianapolis some time ago to manufacture a line of motor cars, has submitted a bid of $100,100 for the plant of the T. B. Laycock Manufacturing Company, which is in the hands of a receiver. It is understood, however, that the court will order the receiver to reject the bid, on the ground that it is too low. Fred I. Tone is president of the Tone company, which hopes to find a location soon so that active operations may be started.

Toner Leaves Flanders Company

DETROIT, MICH., Jan. 13—Thomas Toner, assistant sales director of the Flanders Motor Company, has resigned. His successor has not been chosen as yet. Mr. Toner says he has several offers under consideration, but has not decided anything definitely except that he will stick to the automobile business. He declares he has not had a vacation in 7 years and that he will take a good rest before going to work again.

The Drouet-Page Company has been formed to handle the Palmer-Singer cars in New York, Brooklyn and Westchester. Henry Drouet is president and Fred H. Page, sec-treas.

The New York bankers are selling at 100 and accrued dividends $1,000,000 worth of the 7 per cent. cumulative preferred stock of the recently formed Stewart-Warner Speedometer Corporation. Financial statements place the combined net earnings for last year of the Stewart and Warner companies in excess of $925,000.

London Rubber Sale Opened

The leading event in the crude rubber trade during the last week was the opening of the fortnightly sale of plantation grades in London. There was a good demand and the sale started at firm prices, but later on an easier tone developed.

127,287 Automobiles Manufactured in 1909

Government Census Report Shows Production for That Year To Be Thirty Times That of 1899

U. S. Post Office Department To Take Bids for 100 Additional Motor Vehicles For Parcels Post Service

WASHINGTON, D. C., Jan. 11—An abstract of the full census report has just been issued by Director Durand, in which he makes the following report relative to autcbiles:

"The growth of the automobile industry has been phenomenal. In 1899 the general statistics for the industry were included with those for carriages and wagon manufacture, and only 3,897 automobiles were reported. In 1904, the total number, including automobiles made by the concerns classified under other industries, was 22,830, while in 1909 the number was 127,287, or nearly thirty times the number reported in 1899. The value of all products of the industry proper was $249,202,075 in 1909 and $30,033,536 in 1904. Gasoline machines formed 95.1 per cent. of the total number made in 1909 and 86.2 per cent. in 1904. Of the total manufactured in 1909, 3,226, or 2.5 per cent., were rated at 50 horsepower or more; 51,218, or 40.5 per cent., at from 30 to 49 horsepower; 35,257, or 27.8 per cent., at from 20 to 39 horsepower; 29,353, or 23.2 per cent., at from 10 to 19 horsepower, and 7,539, or 6 per cent., at less than 10 horsepower. Passenger vehicles constituted 97.4 per cent. of the total number and business vehicles 2.6 per cent.

In addition 694 automobiles, valued at $830,080, and bodies and parts, valued at $4,415,266, were made by establishments engaged primarily in the manufacture of products other than those covered by the industry designated.

U. S. to Buy 100 More Trucks for P. P.

WASHINGUTON, D. C., Jan. 15—Postmaster General Hitchcock decided today to take in bids for the U. S. Mail department, on 100 trucks suitable to take care of the rapidly increasing parcels post work in cities. All these trucks will be painted red, which color is to be adopted as standard for postal vehicles.

Reports from forty-eight representative post offices show that for the first week of the parcels post system, from January 1 to 7, a total of 1,989,687 pieces of matter were handled by these offices. No estimate of the receipts in money have yet been made, but officials at Washington state that the new system has already exceeded all expectations. During the first week 76,500 incoming packages were received at the New York office, while 371,800 outgoing parcels were handled, bringing the total to 448,300. Naturally, this was the greatest amount of business done by any city. Chicago comes next with 438,000 pieces handled; Philadelphia reports 146,595, while Jersey City totaled 60,000.

With such a large amount of business when the system is yet in its infancy, there can be no doubt of the benefit which makers of light and medium commercial vehicles will derive from the project when it actually gets under way.

Court Holds Prest-O-Lite Patents Dead

CHICAGO, ILL., Jan. 8—Decision was rendered yesterday in the United States Circuit Court of Appeals, Seventh Circuit, against the Presto-O-Lite Company, of Indianapolis, in the appeal of the patent infringement suit filed by them last spring in the Circuit Court, as it was defeated last June. The original suit was denied in the United States Circuit Court by Judge Kohlsaat and the present suit is an appeal to the Circuit Court of Appeals by the Indianapolis interests. The case was heard by Judges Baker, Seaman and Humphrey and the former decision was affirmed in the decree handed down yesterday by Judge Humphrey. Attorneys Weinter, Bartlett and Hamill represented the Prest-O-Lite company and Parkons and Lane defended the Searchlight company. The suit was brought by the Commercial Acetylene Company, holder of the Claude and Hess letters patent No. 664,383 and the Prest-O-Lite Company, sole holders of license from the Commercial Acetylene Company to manufacture under the Claude and Hess patents. These patents refer to a closed vessel, containing a supersaturated solution of acetylene gas supplied with a reducing valve for the release of the gas at substantially uniform pressure, and expire on their face December 5, 1917, after considerable favorable litigation, starting February, 1909, in which the Avery Portable Light Company, of Milwaukee, was restrained from further manufacture and sale of its product, followed by similar action against the Auto Tank Manufacturing Company, the Acme Acetylene Appliance Company and the Des Moines Auto Gas Company. Judge Kohlsaat rendered the first decision against the Prest-O-Lite interests in refusing to grant a motion for a preliminary injunction against the Searchlight Gas Company on April 26, 1912. He ruled that the American patents had expired by reason of the expiration of the British patents held identical with the Claude and Hess patents. The Prest-O-Lite company then brought suit in the Circuit Court, charging infringement, and was defeated again. In the appeal just decided the defendant claims non-infringement on the grounds of the expiration of the British patents.

Michigan Wants Better Gasoline

DETROIT, MICH., Jan. 12—Every Michigan automobile owner is interested in a bill prepared for the Legislature by Representative L. J. Wolcott, of Albion. The bill is aimed to regulate the sale and quality of gasoline in Michigan. It provides for a specific gravity of at least 60 degrees Beaumé for all gasoline and the labeling of all containers with the specific gravity of the gasoline they hold. All below 60 degrees must be labelled "naphtha." The bill also provides for state inspection of all gasoline, the law on the statute books at present providing only for the inspection of kerosene. The fact that the price of gasoline in Michigan has been increased from 10 cents per gallon to 15 1-2 cents per gallon in the last year without any increase in the quality is given by Representative Wolcott as his reason for the bill. He declares at the present time much of the gasoline being sold in the state is no better than naphtha.

Government Truck Contracts Awarded

WASHINGTON, D. C., Jan. 11—After having the bids under consideration for nearly 2 months the general supply committee has awarded the following contracts for furnishing motor trucks to the government during the balance of the fiscal year: The White Company, Cleveland, O., 1,500-pound and 2,000-pound trucks, $1,950; 3,000-pound trucks, $2,750. The Hupp Motor Car Company, Detroit, 1,000-pound trucks, $950. It is expected nearly a dozen trucks will be purchased under this contract, and at its expiration it is likely new bids will be invited. The trucks will be used in Washington.

Franklin Capital Jumps to $1,500,000

SYRACUSE, N. Y., Jan. 13—The capital of the H. H. Franklin Manufacturing Company has been increased from $300,000 to $1,500,000 which consists of 9,000 shares of common stock and 6,000 of 7 per cent. cumulative preferred stock.

A.A.A. Committee Meets

[illegible]

President Enos Recommends Appointment of Committee on National Reliability Tour of Commercial Vehicles

Next Annual Meeting of the Association to Take Place in Richmond—Date To Be Decided in June

AT Tuesday's meeting of the executive committee of the American Automobile Association two resolutions were read and approved from President Enos, who was too ill to attend, one of these being a recommendation to appoint a committee to take up with the National Association of Automobile Manufacturers the subject of a national reliability tour of commercial vehicles during the coming summer; and the other to appoint a committee on the subject of the national reliability tour of passenger vehicles. The outcome of the tour of commercial vehicles will largely depend on how the suggestion is received by the manufacturers. It is more than possible that the national passenger vehicle tour for this year will not be over the course laid out for last season, namely, from Detroit to New Orleans. At present Minneapolis is bidding for the tour with the object of running it from the Twin Cities to the Black Hills of Dakota and return. Dr. Dutton, president of the Minnesota state association, is fathering the movement.

Ex-President Hooper was presented with a gold watch, in appreciation of services rendered.

Preston Belvin of Richmond, Va., asked that the annual meeting of the association, which will take place in Richmond during the coming fall or winter, be held between November 1 and 15 instead of in December as at present. The matter will be decided at the semi-annual meeting to be held in Philadelphia in June. Mr. Belvin also moved for a consolidated tour at the time of the annual meeting, the tourists from all sections meeting in Richmond and spending a week there for the meeting.

Big Matheson Agency for Canada

MONTREAL, CAN., Jan. 11—The organization has just been completed of the Matheson Automobile Company of Canada, Ltd., incorporated with a fully paid capital of $50,000, all of which is common stock. The company is the Canadian distributor of two makes of automobiles manufactured in the United States, namely, the Matheson Silent Six, manufactured at Wilkes-Barre, Pa., by the Matheson Automobile Company, and a line of four and six-cylinder cars manufactured by the Auburn Automobile Company, Auburn, Ind.

The directorate of the new company is exceptionally strong, and numbers among its members some of the financially strongest men in Montreal. The officers and board are as follows: President, W. W. Butler, vice-president of the Canadian Car & Foundry Company; vice-president, H. A. Dorsey, president of the Dominion Park, Limited; L. H. Timmins, president of the Hollinger Gold Mines, Limited; N. A. Duncan, general manager of the Canadian Car & Foundries, Limited; F. A. Skelton, secretary and treasurer of the Canadian Car & Foundries Company, Limited; W. Carruthers, of James Carruthers & Company, grain merchants; L. J. Perron, attorney.

The sales organization is under the charge of two experienced and well-known automobile men, J. Scott Innes and G. C. Murray.

New Jersey To Use Convicts on Roads

The conversion of New Jersey, a northern state, to the plan of prison labor will be of much interest to all good roads promoters of the country. For several years some of the southern states have been employing convict labor almost exclusively on road work, but in many of the northern states the plan has met with more or less opposition.

Col. Edwin A. Stevens, state road commissioner of New Jersey, after one season's trial of convict labor on the roads of his state, is enthusiastic in indorsing the policy generally. In a communication to the A. A. A. National Good Roads Board the commissioner writes:

"The experiment of convict labor on state roads, which was proved to be a success in one week, is only the beginning of good road building beyond what we already have and at a price which will spread out the money of the state beyond its present confines."

Minnesota Has 28,700 Automobiles

MINNEAPOLIS, MINN., Jan. 13—In 1912, 28,700 automobiles were registered by owners in Minnesota. This is an increase of 17,075 over 1910 and 9,425 over 1911. This increase at an average price of $1,000 a car means that $9,425,000 has been spent by Minnesota people in buying new cars in the year just closed. R. B. Anderson, Minneapolis, publisher of the State official automobile guide, reports that registration is continuing rapidly in 1913. His figures are as follows: 1910, 11,625; 1911, 9,275; 1912, 28,700. Beginning in 1912, automobile license tags were issued for 3 years each at $1.50 for the 3 years. The State book of licenses was issued June 1 and monthly bulletins have been issued since that time to keep the list up to date for subscribers.

Delaware Needs Automobile Commissioner

WILMINGTON, DEL., Jan. 13—Governor Pennewill, in his biennial message to the General Assembly, recommending the establishment of a state commissioner of motor vehicles, whose duty it shall be to issue the licenses for all motor vehicles and their operators and have general supervision over the use of such vehicles in the state. The chief object, aside from relieving the secretary of state of the duty of issuing the licenses, being to provide a state officer who can give direct attention to the enforcement of the law.

Franklin Men Meet at Factory

SYRACUSE, N. Y., Jan. 11—A conference of Franklin Pacific Coast dealers was held at the Franklin factory Friday, January 10, with John F. McLain, Pacific Coast district manager, presiding. Among those present were Ralph C. Hamlin, of Los Angeles, Cal.; Louis Normandin and F. B. Campen, of San José, Cal.; W. M. McCormach, of Pendleton, Ore.; R. H. Tuttle, of Walla Walla, Wash., and J. A. Nichols, Jr., of North Yakima, Wash.

Other Franklin men who attended the conference were C. H. Rockwell, Cleveland district manager; F. H. Sanders, Cincinnati district manager; W. J. Marshall, of Detroit, Mich.; J. J. O'Keefe, of Wheeling, W. Va.; A. Auble, Jr., of Akron, O.; Guy L. Smith, of Omaha, Neb.; S. C. Crane, of Dayton, O.; Murray Carr, of Pittsburgh, Pa.; O. C. Belt, of Columbus, O., and W. G. Langley, of Dallas, Tex.

After the conference the Pacific Coast men went to New York to attend the automobile show.

PIERRE, S. D., Jan. 12—The Good Roads League of South Dakota is going to push its plans before the State legislature. It will ask that convict labor be employed on State highways; that the good roads fund be increased by converting $40,000 now in the State game fund to the good roads fund; that the income from taxing automobiles be turned into the good roads fund and that the annual license fee be increased.

New York Club Formed

Aim Is To Provide Social and Protective Connection Between Automobile Owners in the City

Concerted Action To Be Taken for Saner Municipal and State Legislation—Three Types of Membership

IN order to provide social connection between automobile owners of New York City and to unite them for concerted action in support of the various organizations which are now working for saner city and state legislation, the Automobile Club of New York has been organized, with temporary headquarters at 1737 Broadway. Other aims of this club are to stimulate the public interest in automobile matters and bring about a closer relation between automobile users and trade.

The temporary headquarters contain the offices, lounging and reading rooms, but the permanent accommodations on Columbus Circle, which will be ready by September next, will include, besides these rooms, assembly and exhibition halls, dining and sleeping rooms, gymnasium, swimming pool and roof garden.

It is expected that the club will have a membership of several hundred automobilists shortly, judging by the great interest which is being taken in this matter by New York users of cars and trade members. Some of the most prominent people of New York, interested in the automobile business, have taken out memberships so far. There are three types of memberships, the founder membership limited to 500, at $25 a year, membership for New York City residents at $50 a year and out-of-town membership at $25 a year.

Motor Boosters Dine—The Big Village Motor Boosters' Dinner was held Tuesday evening in New York City. It was attended by about 300 enthusiasts, many who were from out of town. The Hoosier State was well represented.

Wisconsin's Governor on Automobiles

MADISON, WIS., Jan. 14—For the first time in the history of Wisconsin, the automobile, its use, operation and the consequences thereof received treatment in the biennial message of the governor of Wisconsin, at the opening of the 1913 Wisconsin Legislature on January 9 at the Capitol buildings in this city.

The governor arrives at the conclusion that after all the proper theory of taxing motor cars is on the basis of the effect their use and operation may result in by reason of wear and tear on roads. Thus, he suggests, the present uniform license fee of $5 per car per year be changed so that owners be required to pay a fee based on the weight or horsepower, the lightest cars to pay a minimum and the heaviest and highest-powered cars to pay a maximum fee.

The proceeds of this tax, the governor says, should accrue to the state highway fund, instead of being parcelled out *pro rata* to the county as at present, so that there may be more intelligent and efficient work in the direction of constructing and maintaining lines of traffic in continuity, to connect the principal villages and cities of the state and eventually result in a system of state highways.

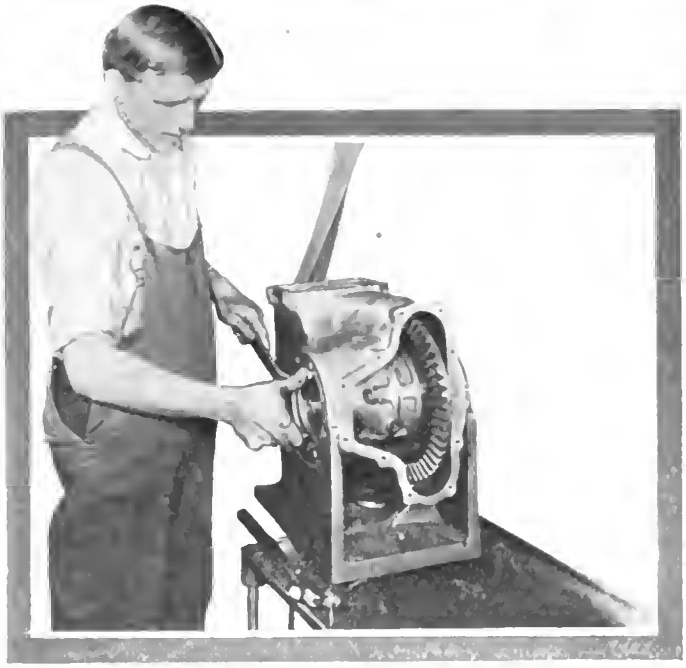
The employment of Wisconsin convicts in the building of permanent highways is urgently advocated by the governor.

Corrections on Electric Issue—In the Electric issue of THE AUTOMOBILE, January 2, captions were transposed on two photographic reproductions of the Ohio electric cars. The photograph at the lower right, page 15 should have appeared as "Ohio Straight Line Brougham. Price $3,200," and that in the lower left corner of page 17 as Ohio Semi-colonial Brougham, $2,900.

In the January 2 issue of THE AUTOMOBILE, page 18, the statement was made that the Bailey long roadster presented last year has not been continued. This roadster has been continued for the coming season and is equipped with 60 A-4 or 52 A-6 cells of Edison battery. It has a mileage radius of 80 to 100 and a speed of 25 miles per hour. The controller gives six forward and four reverse variations. This vehicle is fitted with 33 by 4-inch pneumatic tires. It is fitted with wheel steering and mechanical brakes located on the rear axle and countershaft.

On page 1236, in the issue of THE AUTOMOBILE for December 12, the Locomobile line for 1913 is described. In the table giving the motor dimensions models M and R are transposed. In the description of the big six, which is model M, the principal motor dimensions should read: bore, 4.5 inches; stroke, 5.5 inches; wristpin diameter, 1.125 inches; connecting rod length, 12 inches. The horsepower and torque curves of the model M motor are given on page 1238. The oiling system as described on page 1237 is for the four-cylinder, 30-horsepower motor. On the six-cylinder cars, the oil is pumped independently to the main bearings and to the splash troughs.

Franklin Pacific Coast dealers who met in conference at the factory in Syracuse, N. Y., January 10



Some of the manufacturing operations which are most expensive, both in time and money, are those little steps toward the perfected mechanism which are least in the limelight. The picture shows a workman adjusting the bearing in the differential of a White 1.5-ton truck so that the gears will mesh perfectly when the parts are assembled

KEETON Purchases Factory—The Keeton Motor Company, Detroit, Mich., has purchased the automobile plant formerly occupied by the Oliver Motor Car Company, paying $50,000. Immediate plans to enlarge the factory were started and work will be commenced upon the additions at once. The factory buildings, of which there are four, are located on 1¼ acres of ground. In the group are three buildings of modern factory construction 220 feet by 80 feet each and one building 140 feet by 80 feet. With other smaller buildings, the factory will comprise 50,000 square feet. The company's supplies for 1913 have been ordered and are being delivered at present. Active manufacturing started on January 17.

Speedway Plant Planned—The Speedway Tire Company, Louisville, Ky., is the name of a $250,000 concern which will establish a large factory in that city.

Dodge Brothers Award Contracts—Dodge Brothers, Detroit, Mich., manufacturers of automobiles, have awarded contracts for the erection of a new brick heat treatment building.

Reo Plant Completed—The Reo Motor Car Company, Lansing, Mich., advises that it is not in the market for equipment, as its new assembling plant has been completed and equipped.

General Vehicle's Factory—The General Vehicle Company, New York City, has plans for a large factory which will be erected in the automobile manufacturing district of Long Island City, N. Y.

Petersborough Establishes Factory—The Petersborough Machine & Lubricator Company, Ltd., Petersborough, Ont., recently incorporated at a capital of $600,000, will establish a plant for the manufacture of motors, etc.

New Concern Operates Plant—The plant of the American Automobile Manufacturing Company, New Albany, Ind., which failed some time ago, is to be operated by a new concern known as the Ohio Falls Motor Car Company.

Biggest Automobile Factory—What is declared will be the largest automobile factory in the world is shortly to be erected at Bridgeport, O., by the Bridgeport Auto Company, which has recently been organized with nominal capital of $5,000.

Ford's St. Louis Plant—The Ford Motor Car Company, Detroit, Mich., which recently began construction of an assembling plant at St. Louis, Mo., has bought additional ground for the enlargement of the plant as originally contemplated.

Amherst Firm Completes Plant—The Nova Scotia Carriage & Motor Car Company has completed a new four-story factory at Amherst, N. S. The main building is 300 feet by 100 feet. The office and power house are situated in separate buildings.

Cumberland's Pineville Factory—The Cumberland Motor Company is to establish a factory at Pineville, Ky., for the manufacture of a patented spring motor to be used in the operation of sewing machines. Machine tools are the principal items to be purchased.

Maritime's Coldbrook Plant—The Maritime Motor Car Company, St. John, N. B., is erecting a plant at Coldbrook, N. B., for the manufacture of automobiles. The buildings, two in number and each 250 feet by 100 feet, will be equipped with electrically-driven machinery.

Lee & Porter Building—The Lee & Porter Manufacturing Company, Dowagiac, Mich., is preparing to erect a frame addition to its plant, 32 feet by 90 feet. The installation of about $8,000 worth of machinery is also planned. The company expects to manufacture automobile axles on a large scale.

Gunn's Factory—The Gunn Motor Car Company, Utica, N. Y., has let a contract for additions to its plant, which will include a reinforced concrete building, 60 feet by 175 feet, two stories high, a kiln building 22 feet by 104 feet and a power plant 45 feet by 60 feet with a radial brick chimney 11 feet high.

Abbott Abolishes Factory Office—The management of the Abbott Motor Company has abolished the office of factory manager, the duties formerly attached to this position being divided between the general manager and the factory superintendent. G. C. Shoemaker continues as factory superintendent in charge of all production.

Akron Plant to Be Rebuilt—The International Harvester Company, Akron, O., which sustained the loss of several large buildings at its plant, after securing a promise from the city authorities, for better fire protection, announces that the plant will be rebuilt. The concern manufactures automobiles almost exclusively at the plant.

Jonas & Pimmat's Factory—Jonas & Pimmat, Syracuse, N. Y., have completed their new factory, which is of cement block construction, cement floors and steam heat, with electric lights at each workman's bench. The force of workmen will be doubled by spring. The company manufactures automobile accessories, including tonneau tops.

Albion's Canadian Factory—The Albion Motor Car Company, Ltd., of Glasgow, Scotland, has recently made arrangements with Montreal, Quebec, people to establish a factory garage for assembling commercial cars in that city, and it is intended in the near future to manufacture these cars in that country. There are some sixty Albion trucks running in Canada.

Purchases Vulcanizing Plant—The vulcanizing plant of the Canadian Consolidated Rubber Company, Vancouver, B. C., has been purchased by E. W. Starke. The plant is up-to-date and well equipped in every department. A vulcanizing plant equipped to handle everything in vulcanizing, retreading and tube work is part of the business. Besides there is machinery for putting on solid tires and other work of a similar nature.

Bridgeport Will Erect—The Bridgeport Auto Company, Wheeling, Va., will erect a factory.

McKinnon's Plant—The McKinnon Motor Vehicles, Ltd., Toronto, Ont., recently incorporated with a capital of $100,000 to manufacture automobiles, will establish a plant.

Aldis Briscoe Superintendent—Fred Aldis has been made superintendent of the Briscoe Manufacturing Company's plant in Detroit, Mich. He succeeds F. C. Farlinger.

Speedway's Factory—The Speedway Tyre Company, Louisville, Ky., recently incorporated, has selected three factory sites, and when one is selected an eight-story concrete building will be put up.

Streator Plant Sold—Pursuant to a decree of the United States District Court at Peoria, Ill., the plant, stock and other assets of the Streator Motor Car Company, Streator, Ill., was offered for sale at auction on January 14.

Cataract Rubber's Addition—The Cataract Rubber Company, headquarters at Buffalo, N. Y., plans to erect an addition to the Wooster, O., plant at which solid tires will be manufactured. I. C. Emery is the superintendent. The addition will be ready for occupancy May 1, and will cost $100,000.

Speedwell Adds Machine Shop—Stockholders of the Speedwell Motor Car Company, Dayton, O., ratified a plan to authorize a bond issue of $150,000 for extension of business. The Speedwell company will use Mead sleeve type of engine in place of the Continental or poppet type. A machine shop will be added to the plant.

Maxwell Factory Manager Leaves—Christian Pretz, for several years factory manager of the Maxwell-Briscoe Motor Company, was honored by a dinner at Tarrytown, N. Y., recently. The occasion was a sort of farewell affair to the employees of that plant, many of whom will remove to the Newcastle, Ind., plant, to which place most of the machinery already has been shipped.

Penn Sale January 21—The date of the sale of the Penn Automobile Company, near Newcastle, Pa., has been set for January 21. There are said to be two groups of men interested in the sale, one of which expects to continue the manufacture of automobiles, chiefly commercial vehicles; the other group would remodel the plant so as to make it suitable for other manufacturing purposes.

Assignee Sells Canadian Plant—The Harding Motor Car Company, Ltd., of London, Ont., which undertook to build cars in that Canadian city about a year ago, was sold by the assignee on January 14. The assets are appraised at $24,176, of which plant, machinery, patterns, tools and equipment are valued at $14,583.90, and stock in trade, which includes finished and unfinished parts, $9,190.71. The remaining $400 represents a demonstrating runabout.

Ford Ships 868 Cars—Enlargements on the Ford Motor Company's factory at Detroit, Mich., which have been under way for some months were completed shortly after the middle of December. As a result the output of the Ford factory has been enormously increased. In a single day, December 23, there were shipped from the Ford factory 868 cars, and during the month of December a total of 11,181 cars were produced by that company.

Three-quarter view of the plant of the Peninsular Steel Castings Company, Wight and Iron streets, Detroit, Mich. The company moved into the building shortly after its organization in November

Exhibit of the American Motors Company at the recent automobile show held in Sydney, Australia

AMERICAN'S Australian Exhibit—An evidence of the growing popularity of the American cars abroad, was the exhibit of the American underslung, made by the American Motors Company, Indianapolis, Ind., in the automobile show held recently in Sydney, Australia. Three models, the Traveler, Tourist, and Scout and a chassis were exhibited.

New Columbus Tire Concern—The Columbus, O., Auto Tire Company is the name of a new concern which has opened a vulcanizing and retreading concern. H. R. Anderson is president of the company.

Columbus Supply House Opened—The Automobile Supplies Company is the name of a new concern which has opened in Columbus, O., to handle a full line of automobile supplies. C. S. Holmes is manager.

U. S. Tire's Columbus Branch—The United States Tire Company has opened a Columbus, O., branch located at 89 North Third street. B. L. Crippen, formerly connected with the J. C. Sherwood Rubber Company, is manager.

Syracuse Show Date Changed—Manager Harry T. Gardner, of the Syracuse, N. Y., automobile show, announces to the press and class publications that the official date of the show has been changed from February 25 to March 1, instead of the later date as first selected.

Woodhull Sales Manager—R. S. Woodhull who was manager of the horse-drawn vehicle department of the Columbus Buggy Company, of Columbus, O., has resigned to accept the position of general sales manager of the Ohio Electric Company, of Toledo, O., manufacturer of electric cars.

To Handle Knox Trucks—The Canadian General Electric Company, with head offices in Toronto, Ont., has completed arrangements with the Knox Automobile Company, of Springfield, Mass., to handle the Canadian sales of commercial vehicles and fire apparatus manufactured by the latter company.

Thomas Company Moves—The C. E. Thomas Company, Columbus, O., agent for the Studebaker line of cars, has moved its sales rooms and service department from 264 North Fourth street to a new structure at 166 North Fourth street. The new rooms are 25 by 180 feet and are equipped with a modern repair shop.

Hayes with Abbott—John A. Hayes, formerly connected with the sales department of the Lyon Motor Car Company and United States Motor Company, Detroit, Mich., has been appointed special sales representative for the Abbott Motor Company and left this week for northwest Canada where he will spend some time looking after the company's interests.

Cost of Maintenance High—The Baltimore, Md., authorities are trying to devise a plan to reduce the annual cost of maintenance of the four motor cars used by the Sewerage Commission, water department, city engineer department and street cleaning department which the past year reached close to $12,000. The officials blame improper handling for the high cost and will try to rectify this waste.

California Invests $58,230,000—At the close of business December 31, 1912, the records of Secretary of State Jordan's office shows how California invested approximately $58,230,000 in automobiles and leads the continent in the number of motor cars proclaimed during the past 12 months. The approximate revenue from motor vehicles for 1912 will amount to $75,000. This is an increase of $25,000 over 1911.

Dissolution of Columbus Concern—Dissolution of the Columbus Motor Car & Transportation Company, of Columbus, O., and the distribution of the funds is asked for in a petition filed in court recently by the thirty stockholders of the concern. It is alleged that the company failed to accomplish its purpose which was to compete with the street car company during the strike in Columbus several years ago.

Peculiar Washington Ruling—When the motor of an automobile stops on a railroad crossing and the owner runs up the track 1,000 feet to meet an oncoming train, striking matches, waving his arms and trying to attract the attention of the engineer, the railroad company must reimburse him to the value of the car if the engineer pays no attention and the train demolishes the vehicle. Such was the decision of the Supreme Court of the State of Washington in sustaining the decision of the Pierce County Superior Court in favor of John Nicol against the Oregon-Washington Railroad and Navigation Company.

New Agencies Established During the Week

PLEASURE CARS

Place	Car	Agent
Aledo, Ill.	Moon	E. B. Miller.
Butte, Mont.	Lozier	Motor Car Distrib. Co.
Calgary, Alta.	Cole	Central Gar. & Mach. Shop.
Carcall, Ia.	Moon	Swaney Auto. Co.

Wilkes-Barre, Pa.	Moon	Regal Sales Co.

Abbott Moves—The Abbott Motor Sales Company, Toledo, O., has moved to 1420-22 Madison avenue.

One County Without Automobile—There is only one county in Alabama without an automobile. This is Winston county.

Hermes Builds First Car—The Hermes Motor Car Company, Cincinnati, O., has built its first car. It will be sold for $1,700.

Biddeford Moves—The Biddeford Motor Mart, Biddeford, Me., is now located at 305 Main street. It will handle the Studebaker cars.

Bunnell Moves—The Bunnell Auto Sales Company, Toledo, O., has moved from Erie street into new quarters at 1416 Madison avenue.

Eisenman Branch in Detroit—A Detroit, Mich., branch has been opened by the Eisenman Magneto Company, Germany, at 802 Woodward avenue.

Guatemala's New Decree—By a recent presidential decree all invoices for goods to enter Guatemala must be accompanied by the bill of lading.

Stewart Sales Manager—L. I. Stewart has accepted a position as sales and advertising manager of the Warner Manufacturing Company, Toledo, O.

MacFarland in New Home—The MacFarland Auto Company, Denver, Colo., has moved to 25 Colfax avenue. Its new home is 72 feet by 182 feet.

McCann Secures Faurote—F. L. Faurote has accepted a position with the McCann Advertising Agency, Detroit, Mich., as head of the copy department.

Alabama's Improved Roads—During 1912 the Alabama state highway commission had actual charge of the construction of 118 miles of improved roads.

Gardner Manager Syracuse Show—Harry T. Gardner will manage the annual Syracuse, N. Y., automobile show in place of W. R. Marshall, who has removed to Calgary.

Add to Delivery Equipment—Six automobiles have been added to the delivery equipment at the New Orleans, La., postoffice due to the added business caused by the parcel post.

Quarles Opens New Quarters—The E. B. Quarles Company, Baltimore, Md., representing the Brown scientific pneumatic inner tube, has opened new quarters at 1922 North Charles street.

Syracuse Federal Moves—A. J. Jackson, Syracuse, N. Y., agent for Federal motor trucks, has moved from No. 511 S. Clinton street to No. 571, the same street, thereby doubling his show space.

Conducted on Dealership Basis—The Baltimore, Md., branch of the Franklin Automobile Company, Syracuse, N. Y., has been taken over by W. F. Kneip who will conduct it on a dealership basis. Mr. Kneip is a former Franklin engineer.

Ohio's Convict Labor—Advocates of good roads in Ohio have held frequent consultations with the Ohio State Board of Administration recently with reference to using convicts confined in the Ohio penitentiary for road improvement during 1913.

Oppose Passage of Law—Automobilists in Ohio are preparing to oppose the passage of a law by the legislature, changing the system of registration fees from a flat rate for electrics and gasoline cars, to a sliding scale based on the horsepower of vehicles.

Randall Resigns—F. M. Randall on January 1 resigned as Detroit, Mich., manager of the Charles H. Fuller Company, in order to become associated with Gleeson Murphy in the general management of the middle west organization of the H. K. McCann Company, advertising agents, with headquarters in the Boyer Building, Detroit, Mich.

Studebaker's 10-Year Lease—The Studebaker Corporation has closed for a 10-year lease on a new five-story building at the corner of Peachtree and Harris streets, Atlanta, Ga., which will be used by its southern branch. The consideration is $150,000 for the 10 years.

Manitoba Highway Improvement—A report issued by A. McGillivray, highways commissioner for the province of Manitoba, shows that a sum of over $1,000,000 will be spent during 1913 on the highways of that province. One of the main travelled highways which will receive the greatest attention is that portion of Canadian territory between Winnipeg and the United States boundary line at Emerson.

Correction on Keeton—The Keeton Motor Company, Detroit, Mich., is not an outgrowth of the Croxton-Keeton Company except that Mr. Keeton formerly licensed the Croxton-Keeton Company to build a French type car of his design. The Keeton Motor Car Company makes only one chassis, a six-cylinder, 48-horsepower model, the monobloc motor having a 3.75 inch bore by 5.5 inch stroke with a four-bearing crankshaft. An electric starting and lighting system is fitted.

Pierson Appointed Receiver—Edward W. Pierson has been appointed receiver for the Indianapolis Dash Company, of Indianapolis, Ind., and has given bond in the sum of $25,000. The receiver was appointed on applications made to the superior court by the John Reilly Company and the E. H. McCormack & Sons Company, creditors in excess of $4,000. Several creditors have brought proceedings in the Federal Court to have the company adjudged bankrupt. Included in the liabilities are notes for $21,000 due Indianapolis banks.

Difficulty in Gasoline Contracts—The municipal authorities and other large users of gasoline in Indianapolis, Ind., are finding it difficult to place satisfactory contracts for gasoline for this year. The best figure that is being quoted is one-half cent off of the market price. In the past it has been possible to make contracts at from 9½ cents to 10½ cents a gallon, with the benefit of any reduction below the contract price. Most of the large users are now paying from 14 to 15 cents a gallon for gasoline, while some of the smaller users are paying from 18 to 20 cents a gallon.

The Baldwin Locomotive Company, Philadelphia, recently constructed four gasoline locomotives. The picture shows one of these fitted with a 6 by 6-inch four-cylinder motor and a Hele-Shaw clutch negotiating a 5 per cent grade with a load of 100,000 pounds

First view of the Collegiate Range, Continental Divide, coming into Buena Vista from Trout Creek Canyon, on top of Monarch Pass, crossing the Sangre de Christo Range of the Continental Divide; altitude, 12,000 feet

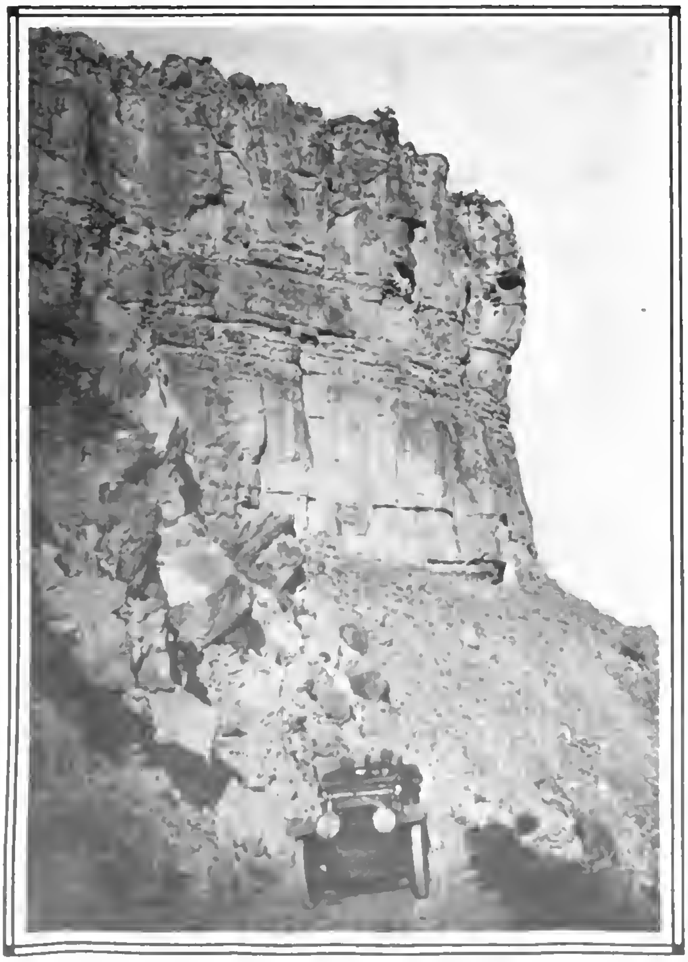
The illustrations shown herewith are made from photographs taken on a recent trip through Colorado in the six-cylinder White car, which is shown in the foreground of each of the pictures

St. Mary's Hose Truck—St. Mary's, O., will have a new motor hose truck, the purchase having been authorized by the city council.

Cary Sales Manager—The International Acheson Graphite Company, Niagara Falls, N. Y., has appointed Richard Cary sales manager of its lubrication department.

Marshall in Concrete Business—W. R. Marshall, secretary of the Syracuse, N. Y., Automobile Dealers' Association, will soon leave for Calgary, Can., to engage in the concrete construction business.

Winnipeg Adds Hose Wagons—Winnipeg, Man., has added two hose wagons to the fire department motor equipment. The latest additions are a Kisselkar and a Commer. Both machines have a capacity for 1,800 feet of hose and six men and are equipped with all the latest accessories for use in fire fighting.



In the Canyon of the Grand River, below Glenwood Springs

Formation of Co-Partnership—Alexander Muir and A. C. Davidson have formed a co-partnership under the name of the Muir-Davidson Steel Company, New York City, to act as general agents in the United States and Canada for the Samuel Fox & Company, Ltd., steel manufacturers of Sheffield, England.

Space at Winnipeg Show—The allotment of space for the Winnipeg motor show, Winnipeg, Man., provides space for twenty-six different exhibitors who will display at least sixty different makes of cars. The building will be most elaborately decorated and the show will be under the management of A. C. Emmett. The dates are February 10 to 15.

Change in Handling Electrics—The Union Electric Light & Power Company, St. Louis, Mo., has announced a change in its method of handling the electric automobile business. It has given up its agencies and will close its garage, as a public garage, just as soon as the customers can be accommodated elsewhere. The firms which the Union Electric Company has represented will shortly open places of their own, and in the future that company will act in an advisory capacity for the good of the business as a whole.

Automobile Incorporations

AUTOMOBILE AND PARTS

Boston, Mass.—Pope Manufacturing Company; capital, $6,500,000; to manufacture automobiles. Incorporators: S. L. Pope, G. Pope, R. P. Clapp.

Baidgeauag, Ont.—League of Canadian Automobilists, Ltd.; $5,000,000: to carry on the business of manufacturers, buyers and sellers of automobiles, motor vehicles and supplies, macbinery, implements, etc. Incorporators: James Steller Lovell, William Bain, Robert Gowans, Joseph Ellis, Samuel Goodman Crowell.

Buffalo, N. Y.—Buffalo Automobile Sales Corporation; capital, $15,000; to manufacture and sell motors, engines, machines, etc. Incorporators: W. J. Harris, W. U. Heverly, Maud MacDonald.

Buffalo, N. Y.—F. A. M. Auto Supply Company; capital, $20,000; to deal in automobiles. Incorporators: F. A. Marburg, J. B. Green, R. H. Templeton.

Cleveland, O.—Anderson Rolled Gear Company; capital, $100,000; to manufacture and deal in machinery and supplies of all kinds. Incorporators: F. A. Barker, D. H. Foster, W. C. Krkkbride, H. N. Anderson, G. H. Sensabaugh, R. M. Calfee.

Cleveland, O.—Alco Motor Company; capital, $10,000; to deal in automobiles, trucks, parts, etc. Incorporators: M. Kluger, C. K. Halle, F. Butler, A. J. Halle, E. L. Geisner.

Cleveland, O.—Forest City Garage Company; capital, $5,000; to deal in automobiles and accessories. Incorporators: Christian Mortx, E. T. Mertz, J. T. Harding, J. W. Wald.

East Orange, N. J.—Rickey Machine Company; capital, $125,000; to deal in sutomobiles. Incorporators: C. A. Hauswirth, M. H. Rickey, F. A. Nott, Jr.

Louisville, Ky.—Standard Automobile Company; capital, $25,000; to deal in automobiles. Incorporators: G. A. Dunham, C. L. Alderaon, J. H. Alderson.

Montreal, Que.—Grenier-Warrington Motor Car Company; capital, $50,000; to manufacture and deal in automobiles. Incorporators: Dr. E. Ostigny, Theopile Viau, J. T. Wsrrington, Aime Grenier, Hector Paiment.

Painesville, O.—Vulcan Msnufacturing Company; capital, $300,000; to manufacture automobiles. Incorporators: E. B. Heartwell, F. H. Murray, J. C. Ward, Wm. Truby, H. E. Hammer.

Building $10,000 Garage—Edward Rudolph, Phoenix, Ariz., agent for the Ford, is building a $10,000 brick garage on East Adams street.

Motor Tractors at Baton Rouge—Motor tractors for farm use will be demonstrated at a farmers convention to be held in Baton Rouge, January 14 and 15.

Hartzell to Manage Goodyear—R. S. Hartzell has been appointed manager of the Cleveland, O., branch of the Goodyear Tire & Rubber Company, Akron, O.

Hutchinson Advertising Manager—F. B. Hutchinson, Jr., has been appointed advertising manager of the Kelly-Springfield Motor Truck Company, Springfield, O.

Firestone Opens Three Branches—The Firestone Tire and Rubber Company, Akron, O., announces the opening of three new branches in Cincinnati, O., Memphis, Tenn., and Milwaukee, Wis.

Inderrieden Sales Manager—A. J. Inderrieden has been appointed eastern district sales manager for the Stewart-Warner Corporation, Beloit, Wis., with headquarters in New York City.

New Orleans Anti-Noise—Open mufflers and oppressive forms of signalling devices on automobiles are to be prohibited by an ordinance now being compiled by the New Orleans, La., commissioner of public safety.

Fisk Opens Winnipeg Branch—The Fisk Rubber Company, of New York, will open on February 1 at Winnipeg, Man., a completely equipped branch house at 307 Fort street. Mr. R. Phillips will be in charge as local manager.

American Changes Name—Announcement has been made that the American Automobile Corporation, New Albany, Ind., has changed its name to the Ohio Falls Motor Car Company, and that the capitalization of the company is $450,000.

Roberts with Mais Truck—W. M. Roberts, sales manager for the Packers Motor Truck Company, Wheeling, W. Va., has resigned his position with that company, to accept a position with the Mais Motor Company, Indianapolis, Ind., as general sales manager.

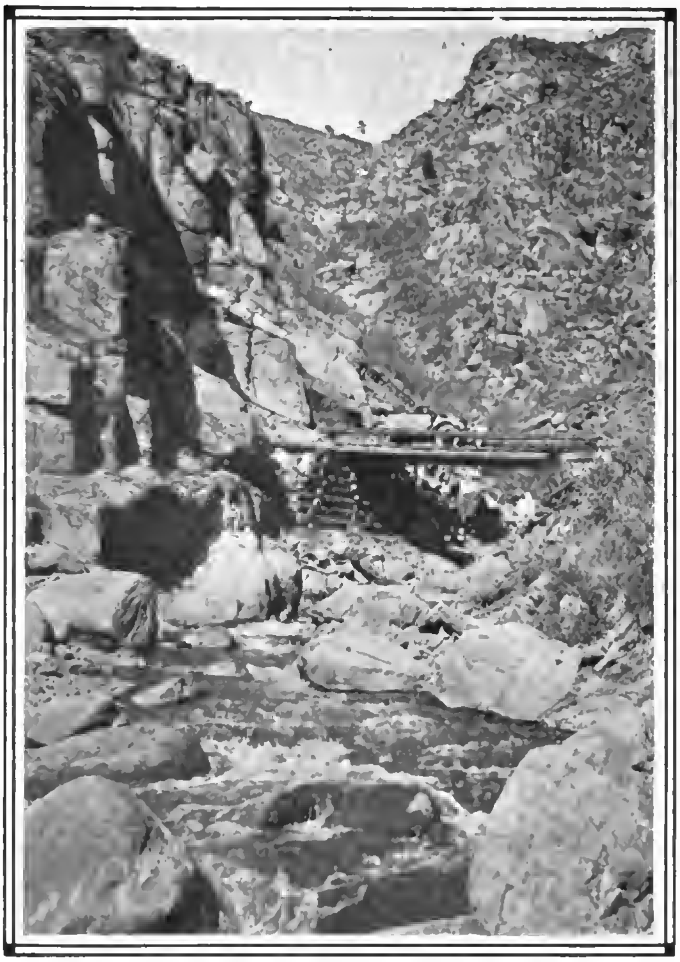
Automobile in Eden—A movement to have the highways of the town of Eden, of which Bar Harbor, Me., is a part, reopened to automobiles, has been instituted. A bill introduced in the legislature provides that the town may open its roads to automobiles.

Ready Resigns from Lozier—W. J. Ready recently resigned his position as superintendent of the Lozier Motor Company, to become manager of the Star Motor Car Company, Ann Arbor, Me., which will manufacture trucks of 1,500 and 2,000-pound capacity.

Lynn Show January 20—The Automobile Dealers' Association of Lynn, Mass., at its annual meeting recently voted to have an automobile show. This will be held during the week of January 20 to 25, at the Eighth Regiment Building. Percy I. Reynolds is secretary-treasurer.

Extends Invitation to Show Visitors—An invitation has been extended by the Miller-Brisben Company of West 63d street, to the out-of-town buyers during the week of the automobile show, extending to them the use of the available cars to facilitate the purposes of these visitors.

Broc Sales Increase—Among the announcements of 1912 sales increases, is one made by the Broc Electric Vehicle Company, Cleveland, O., of practically 100 per cent. for the entire year, and as an evidence of the increasing favor of electrics, may be cited the fact that the Broc management will again double its output of pleasure cars.



In the Phantom Canyon of 4-Mile Creek, near Cripple Creek

Looking down into the Black Canyon of the Gunnison River, 2,000 feet deep

Automobile Incorporations

Pittsburgh, Pa.—Keystone Motor Supply Company; capital, $12,000; to deal in automobiles.

Toledo, O.—Kero Carburetor Company; capital, $25,000; to manufacture and deal in carburetors, engines and parts and accessories. Incorporators: M. O. Rettig, W. J. Brunn, H. C. Lyon, Martha Arndt, W. C. Bugman.

GARAGES AND ACCESSORIES

Brooklyn, N. Y.—Mol Stringer's Garage Corporation; capital, $10,000; to carry on a garage business. Incorporators: Mol Stringer, Jas. Culleeny, F. R. Huntington.

Cleveland, O.—Euclid Square Garage Company; capital, $25,000; to operate storage rooms for automobiles and to carry on a general livery business. Incorporators: C. K. Fauver, J. A. Pritchard, H. E. Downing, H. Allchin.

Elyria, O.—J. & H. Taxicab Company; capital, $2,500; to carry on a general taxicab business. Incorporators: A. L. Jackson, M. F. Harrison, L. B. Fauver.

Louisville, Ky.—Speedway Tire Company; capital, $250,000; to manufacture automobile tires. Incorporators: H. L. Lewman, G. W. Greene.

Tacoma, Wash.—B. Bennett & J. B. Baldy; capital, $5,000; to conduct a garage, tire and vulcanizing plant. Incorporators: W. B. Sbumacker, B. B. Bennett, J. B. Baldy.

Trenton, N. J.—Empire Rubber & Tire Company; capital, $1,000,000; to manufactnre and sell rubber hose, tires, etc. Incorporators: C. H. Baker, C. E. Murray, J. C. Murray.

CHANGES OF CAPITAL AND NAME

Cleveland, O.—Cleveland Auto Livery Company; increase of capital from $10,000 to $25,000.

Cleveland, O.—Stuyvesant Motor Car Company; decrease of capital stock from $200,000 to $10,000.

Indianapolis, Ind.—American Automobile Corporation; change of name to the Ohio Falls Motor Car Company.

Moline, Ill.—Velie Motor Vehicle Company; increase of capital from $600,000 to $800,000.

MECHANICAL WHEEL—In which the tire is supplanted by helical springs which take the place of the ordinary wooden spokes.

This patent refers to a wheel construction in which hub H and rim R, Fig. 1, are not connected by the ordinary type of spoke, but by telescoping spokes S containing helical springs S1. Each spoke is fixed at one of its ends to the hub H and at the other to a block which slidably engages the spoke-supporting elements E secured to the rim R. The helical spring which is contained in the telescoping spoke tubes of each spoke member is reinforced in its longitudinal direction by a rod R1 which projects through a slot in the aforementioned block.

No. 1,049,162—to John H. Sparks, Camden, N. J. Granted December 31, 1912; filed January 30, 1911.

Device for Tire-Tube Repairs—Which comprises two curved springs between which the inner tube is held in place.

Fig. 2 shows the subject matter of this patent, which serves for holding an inner tube in place while repairing it. For this purpose two curved spring members S are used, which are bent toward one another so that their convex faces are nearest along the median lines of both members. The tube is placed between both members S and by applying pressure by means of the wing nuts P, the inner tube is compressed.

No. 1,049,090—to Adolph R. Hoeft, Chicago, Ill. Granted December 31, 1912; filed October 3, 1910.

Automobile Carbureter—Consisting of two concentric float chambers which supply fuel through two separate vaporizing nozzles.

This device, Fig. 3, consists in principle of an outer wall O and an inner one, between which a central chamber C is formed which serves as the mixing chamber of the carbureter. Between the outer and inner walls is an intermediate wall which divides the space surrounding the mixing chamber into two independent, concentric chambers; floats F, F1 are in position in these chambers. Each float chamber has an independent supply pipe through which fuel flows into it, the flow being controlled by valves V and V1 for the float chambers containing floats F and F1, respectively. The valves are controlled by levers suitably fulcrumed at some place on the outer casing and moved by the rising or falling float. By means of nozzles M, which lead from the two float chambers into the central mixing chamber C, fuel is brought into the flow of air which is drawn into the motor by the suction of the latter and thereby vaporized.

No. 1,048,620—to Eugene B. Williams, Stockton, Cal. Granted December 31, 1912; filed May 8, 1912.

Clincher-Tire Rim—Consisting of two rim sections which are brought farther from or nearer to each other by an expansible hoop.

The rim construction described in this patent is shown in Fig. 4 and consists of two rim sections constructed as follows: Each section R is composed of a ring S at a right angle to the wheel axis and of one parallel to this axis. An inclined surface rising from the parallel ring to that which is at a right angle to the axis has its upper flange turned in so as to be capable of holding the bead of a clincher tire in place. An expansible hoop H lies between the two inclined parts of the rim sections and by its varying adjustment serves to space them.

No. 1,049,287—to Samuel Barnett, Tipton, Eng. Granted December 31, 1912; filed September 9, 1912.

Automobile Spring Suspension—Consisting in the use of short curved springs which counteract excessive deformation of the semi-elliptical spring.

The spring invention referred to in this patent is shown in Fig. 5. It consists of semi-elliptical leaf spring S1, the ends of which are attached to members M, while intermediate its length members N are secured to it. To each of these members N are fixed the free ends of a set of strongly curved springs L, the other end of the curved springs being secured to the chassis frame together with the ends of springs attached to the members M. It is clear that while the auxiliary springs do not interfere with normal spring action, they must prevent excessive deformation of the leaves of S1, as well as their recoil and consequent breakage.

No. 1,049,097—to George M. Huston, New York City. Granted December 31, 1912; filed August 7, 1912.

Resilient Automobile Tire—Consisting of a rigid rim and rigid spokes, resiliency being supplied by helical springs between the rim and tread.

The resilent tire described in this patent and shown in Fig. 6 consists of a rim and a tread band surrounding it concentrically. Rim and tread are resiliently spaced by means of a series of helical springs R which seat on projections formed on the rim and tread surfaces. The rim is formed in several sections the ends of which are formed with beveled faces engaging as do E and E1. The outward radial projections of E and E1 are held together by a suitable mechanism, such as a ring locked tight on these ends.

No. 1,049,067—to Otto Erickson and Olaf G. Sunden, Chicago, Ill. Granted December 31, 1912; filed February 17, 1912.

Carbureter Construction—Comprising a double evaporating chamber the parts of which come into action one after another.

This patent dealing with carbureter construction includes the combination of two vaporizing portions having a common outlet, with a throttle adapted to connect first one of the vaporizing portions and then both of them with the outlet. A fuel duct supplies the hydrocarbon fuel and a single valve is used to connect it first with one of the vaporizing and then with both, throttle and fuel regulating valve being operated simultaneously.

No. 1,046,014—to William H. Ratcliff, Newark, N. J. Granted December 3, 1912; filed September 7, 1910.

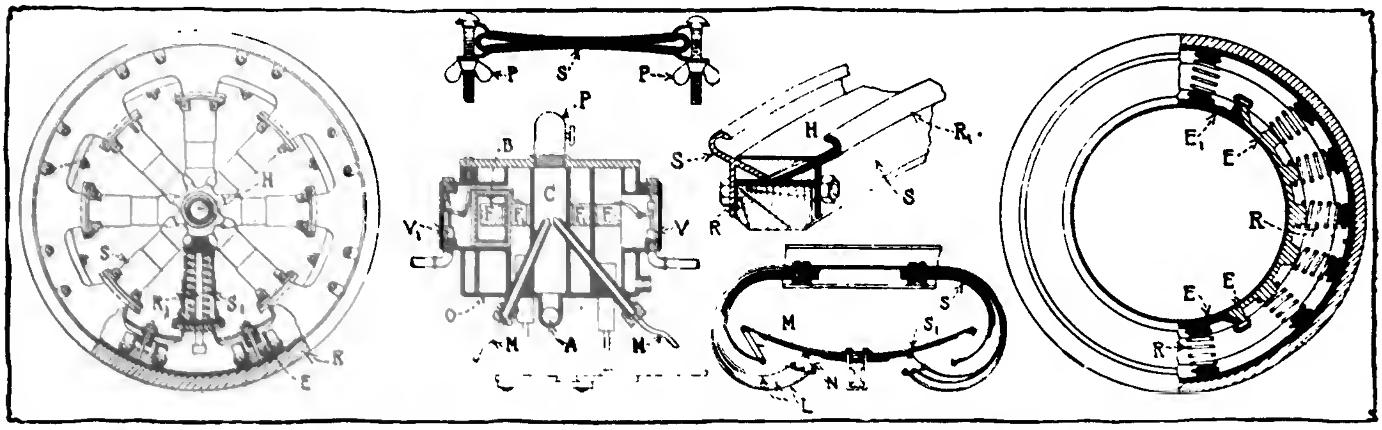


Fig. 1—Sparks mechanical wheel. Fig. 2—Hoeft tube-repair device. Fig. 3—Williams carbureter. Fig. 4—Barnett clincher rim. Fig. 5—Huston spring suspension. Fig. 6—Erickson-Sunden tire

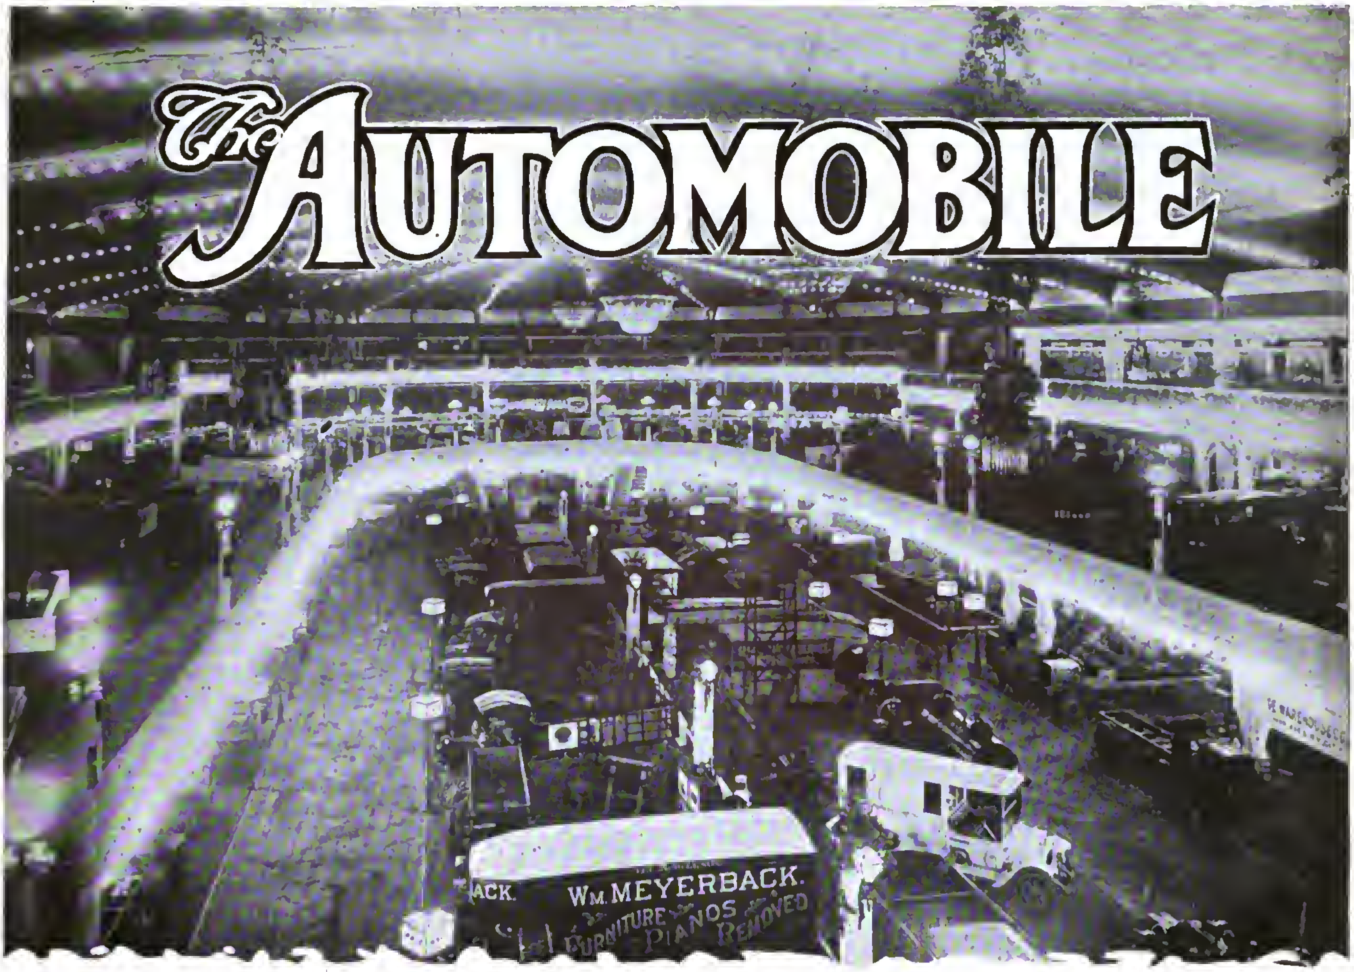
Vol. XXVIII New York—Thursday, January 23, 1913—Chicago No. 4



New York's Truck Show Opens

Sixty Makers of Gasoline Vehicles and Seven of Electrics Attendance Unprecedented—10,000 at Garden Opening Night

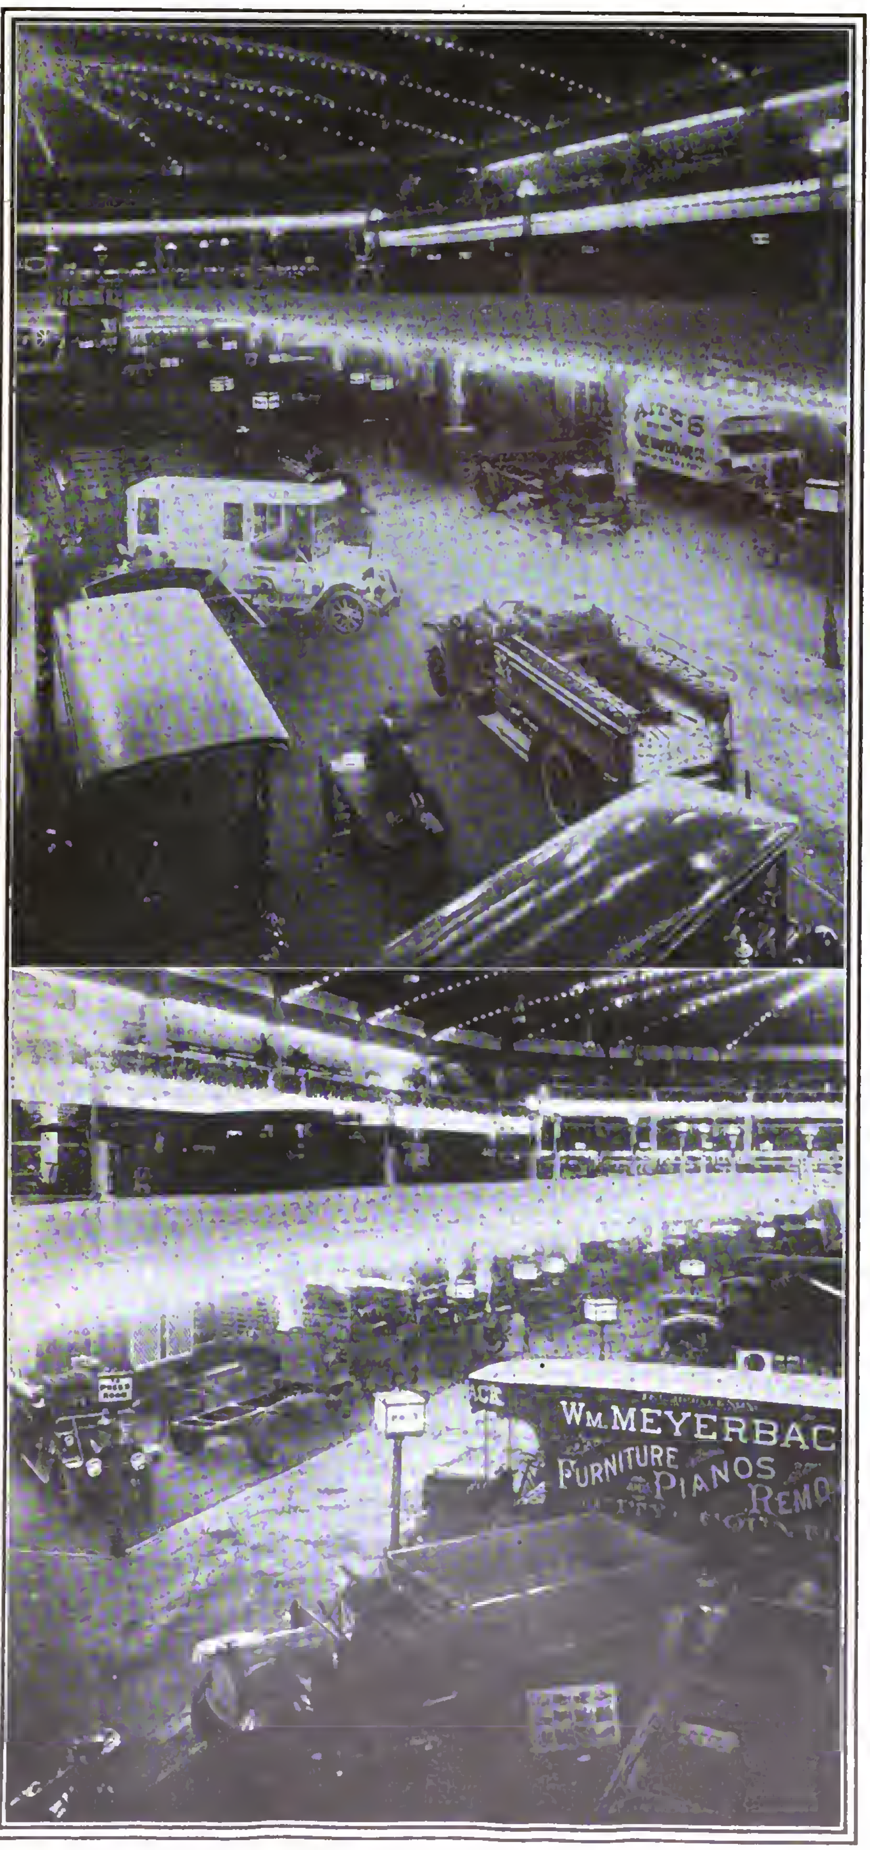
SIXTY makers of gasoline commercial vehicles and seven makers of electric vehicles comprise the truck show which is running simultaneously this week in Madison Square Garden and Grand Central Palace and constituting what history will know as Part Two of the National Automobile Show in New York City for 1913. In addition to these vehicle exhibitors are many accessories for motor trucks and also a machinery exhibit in the Garden basement by members of the National Machine Tool Builders' Association. It is the first time that such a machinery exhibit has been made at an automobile show and the interest that spectators show in the big machines manufacturing automobile parts augurs well for its continuance next season.

Since the inception of the national truck show the public has taken kindly to the exhibition partly because of the mammoth proportions of the huge freight carriers, but also because of the economic part the motor is playing in city and suburban transportation today, and the crowds on opening night gave promise of a greatly increased attendance over that of last year. The show committee has done its part to get the attendance on hand. Invitations have been sent out to all business houses rated above a certain standing within the metropolitan area and every response means a free admission to both shows. The committee can do little more than bring the business men to the Garden or Palace; it is up to the exhibitors and their selling forces to do the rest. Over 10,000 were present at the Garden on opening night.

That the truck industry has made gigantic strides during the last 12 months is apparent on every hand. The vehicles are improved; the methods of selling machines have improved, thanks to the aggression of the National Association of Automobile Manufacturers and the determination of the best makers; the old-line makers have generally increased the number of models so as to cover the entire gamut of industrial transportation; there are over a dozen new faces, and while not a few, who were present a year ago, are missing today, it is not because they have been eliminated from the field, but in some cases due to financial difficulties and in other cases to changes in policy.

The new faces in general represent a class of manufacturers building machines for light-delivery service, ostensibly of the house-to-house delivery variety, the vehicles varying in load capacity from 800 to 1,500 pounds. Some of these new faces seen at the show are Krebs, Brown, Maccar and Koehler, whereas newcomers making larger-capacity models are Hydraulic, Standard, B. A. Gramm and Studebaker.

While the advent of new concerns always adds a glamour of



Two views of New York's Motor Truck Show. Upper—Ground floor of Madison Square Garden, showing the way the trucks are arranged and giving an idea of the exhibits in the gallery. Lower—View down another aisle at the Garden

expectancy to any exhibit there is not any lack of interest with the products of the old concerns because there has been a general adding of models all along the line, and while frequently the new models are largely duplicates of the old ones, there are invariably nice points of interest by way of improved designs or original body conceptions.

Space would scarcely permit to more than suggest a few of the concerns that have added models to fill up the gaps, if the expression may be used, in the lines of last year, so that now the shrewd buyer can without difficulty equip his machines of the same make and having load capacity anywhere between 1,500 pounds and 5 or 7 tons. In this respect the truck program is directly opposite to the trend in passenger car field. A few examples will show the trend:

Packard has added a 5-ton and now has three models, 2, 3.5 and 5 ton.

The International Motors has added a 1,500-pound wagon and its line now embraces 1,500 pounds and 1, 1.5, 2, 3, 4, 5 and 7 Macks; 10-ton Hewitt, and 5 and 6.5-ton Saurer.

Knox has added a 15-20-ton tractor of the Martin-Knox type and its line includes 1.5, 2, 3, 4, 5, 6, 7 and 15-20-ton machines.

The G. M. C. has added three models 3, 3.5 and 5-ton machines to its line of 1.25 and 2-ton trucks and so now thoroughly covers the field up to 5 tons.

Lauth-Juergens has added a 5-ton model and now has 1, 2, 3 and 5-ton machines.

The Garford list of 2, 3, 5 and 6-ton machines has been increased by a 10-ton tractor which in brief is a close-coupled 6-ton truck built to carry the front end of the trailer on a fifth-wheel arrangement.

Mais has added a 3-ton model and now boasts of four models, namely, 1.5, 2, 2.5 and 3 tons capacity.

Pope-Hartford has added to its 3-ton model of last year two others, namely, 1.5 and 5 tons, giving it a wide range of load capacity.

Speedwell has added a 2-ton model to its 4 and 6-ton machines of last season.

Universal has added a worm-driven model of 1-ton capacity and now has 1, 2 and 3-ton models.

The Kissel line has another model of 1.25-ton capacity and gives a line of seven models, namely, .75, 1, 1.25, 2, 3, 4 and 5.

Sternberg has added a 7-ton model to its 1912 line of 2, 3, 4, 5 and 6-ton models.

Space will not permit to enumerate further the general broadening in the models carried; in a word, practically 90 per cent. of the makers have added new models. There are some companies who saw in advance the advantage of a wide range, and have not found it necessary to make additions. In this class are such concerns as White, Peerless, Alco. On the other hand, there are some makers who for the present are confining their efforts to a single model, such as Pierce-Arrow, Locomobile, Lippard-Stewart, Autocar, Stewart, etc.

There are not a few points of interest in the present show besides new faces, new models and new designs. Among these are the new Hydraulic truck, made without clutch or gearbox, but having instead an hydraulic pump and motor system. The gasoline engine drives an oil pump which in turn delivers the oil and drives two hydraulic motors, attached respectively to the right and left rear road wheels.

Also seen for the first time is the French Latil truck with front-wheel drive. It is in the booth of the Walter company, which concern is going to manufacture this type in America. The four-cylinder motor, clutch and gearbox are all nested between the front road wheels. The drive is by short shafts with universal joints through spur pinions into large gears on the road wheels.

Third comes the big 15-20-ton Knox-Martin tractor and also the 10-ton Garford tractor.

Reverting to the new faces at the show and the new models, perhaps the new Studebaker line of gasoline trucks, seen for the first time, is arousing as much interest as any others. This line is most complete, including 1-2, 3-4 and 5-6-ton machines, all designed on the same general lines. The trucks are conventional, using four-cylinder motors under the hood, a gearbox in unit with the motor and shaft drive to a jackshaft, which drives by inclosed spur pinion to large gears on the rear wheels. The motors are governed from the gearbox and not from the crankshaft or other motor shafts.

The Kelly line is entirely changed from last year and now consists of two four-cylinder water-cooled models with Renault type hoods, namely, radiator in rear of the motor. Both have left-hand steering with center control. The 3-ton has T-head cylinders cast in pairs; the 1-ton uses an L-type block casting. Both are shaft-driven models with the gearbox a unit with the rear axle.

The Gramm company has added a 1,500-pound wagon known as the Willys Utility wagon. It is a conventional motor-under-the-hood type using a four-cylinder motor with unit jackshaft and gearbox and with side-chain drive from the jackshaft to the rear wheels.

Reo has added a 1.5-ton four-cylinder model, made up of a motor and gearset of similar design to that used in the passenger car. Chain drive is used.

Buick is out with two new models of 1,000 and 1,500 pounds capacity. The design is a motor-under-the-hood type and uses a four-cylinder block motor, three-speed gearset and shaft drive.

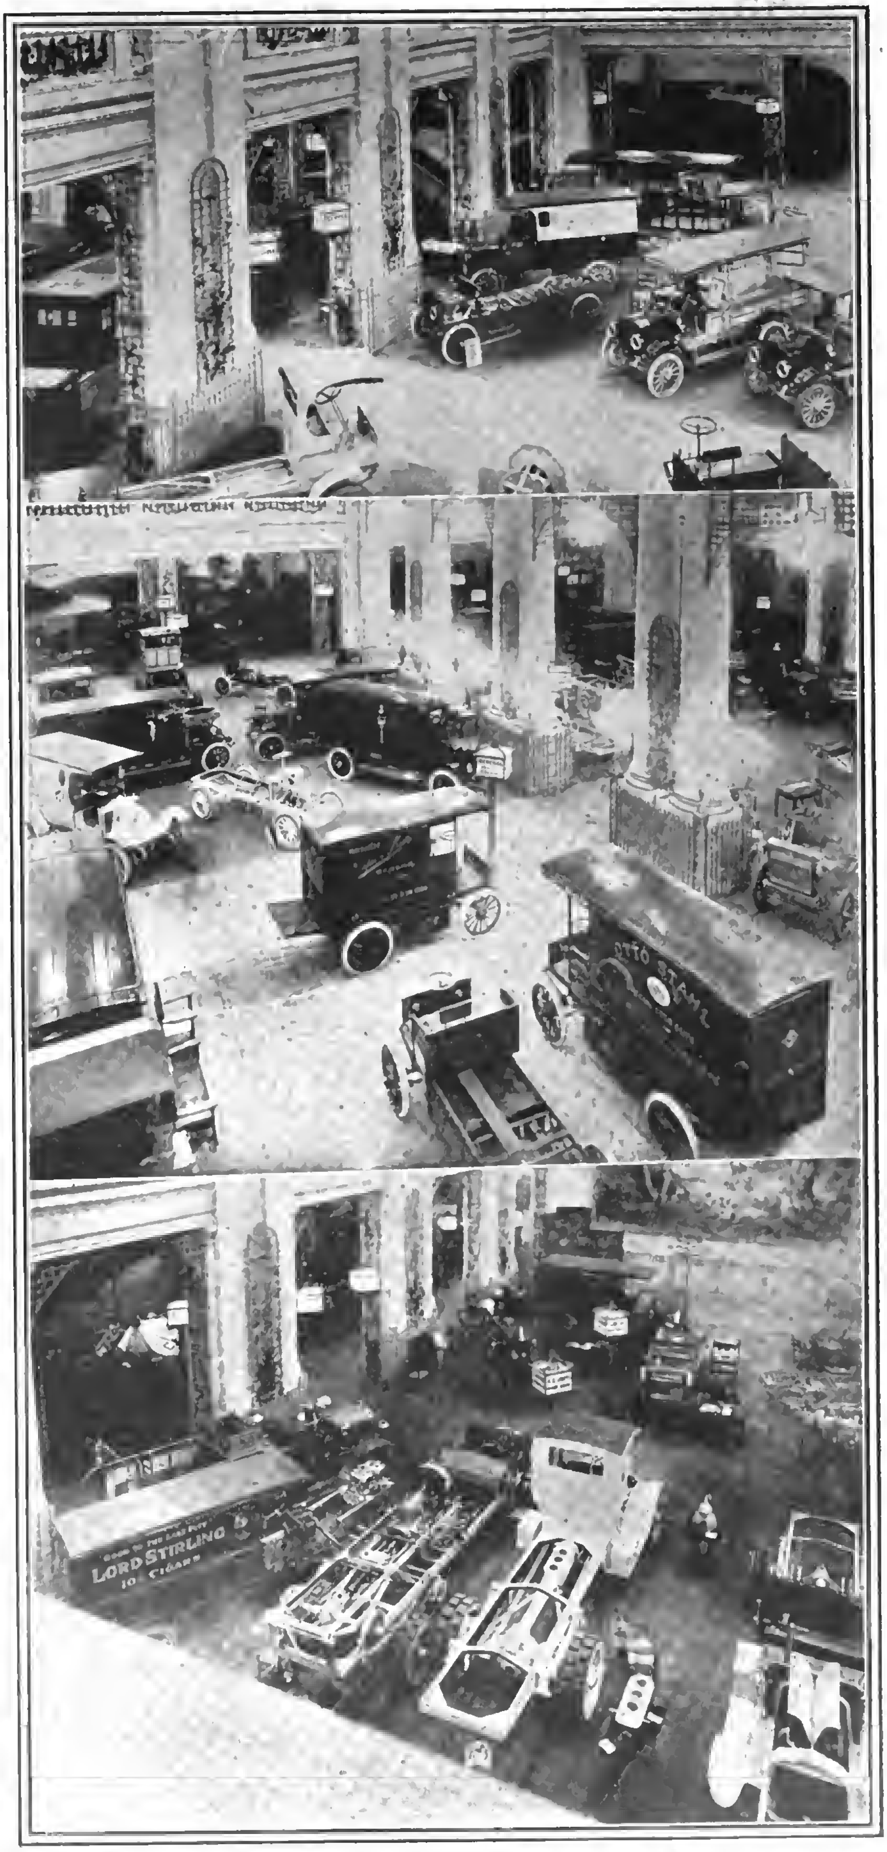
The new Brown delivery wagon of 1,500 pounds capacity has the motor under the hood, uses a block design, uses shaft drive and fits a combination stationary and live rear axle, the drive shafts of which transmit through spur gears to the road wheels.

The Krebs, a new concern, which announced two-cycle models in the early fall, is manufacturing these in 1,500 pounds and 1-ton models and has added a 1.5-ton four-cycle model built on the Renault-hood lines with the block motor accessible in front of the radiator, forms the dash. The motor has four cylinders.

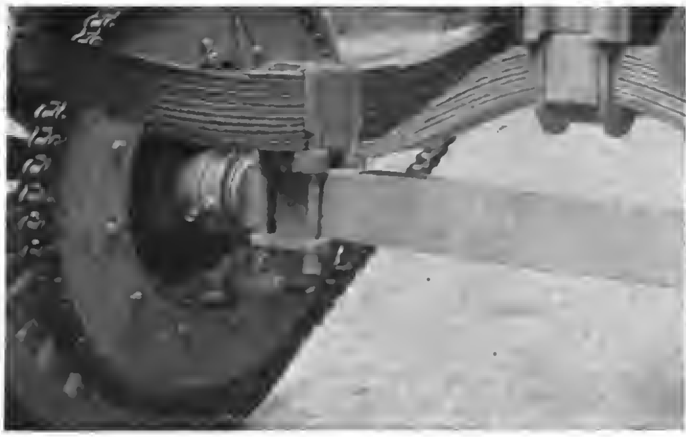
Maccar is one of the newest machines at the Palace and is the design of J. M. Mack, recently of the Mack company. It is a four-cylinder motor-under-the-hood style with gearbox in unit with the motor and shaft drive. There are two sizes, one 1,500 pounds, the other 1 ton.

The Vulcan trucks, seen for the first time at a National show and announced during the past summer, are made in 2, 3, 4, 5, 6 and 7-ton sizes. They place the four-cylinder motor under the hood, use a patented gearset which greatly simplifies gearshifting and employ chain drive.

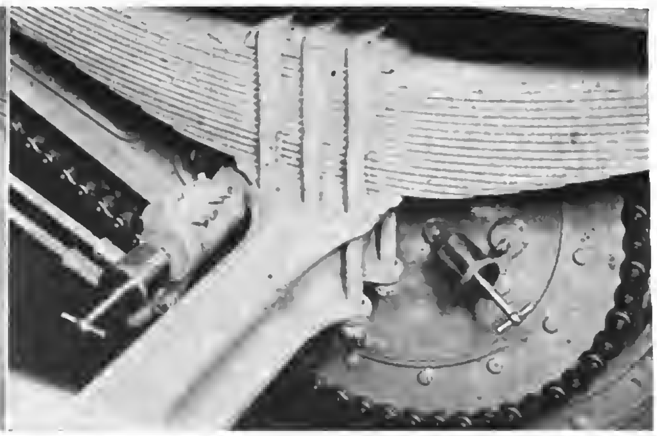
This narration of new faces and new models could be continued much longer, but



Three views of the division of the Motor Truck Show at Grand Central Palace. Top—One-quarter view of the ground floor looking toward aisle. Middle—View across central part of the main floor. Bottom—Cross-view of the back of the hall



Auxiliary spring on KisselKar which comes into play when the truck is heavily loaded



Mounting of rear springs on Kelly, showing accessible grease cups and large chain sprocket

the different types will be treated individually at a later date.

Again taking up the thread of general tendencies as exhibited by the sixty makers of gasoline machines on exhibition, it is possible to trace with fair accuracy not a few certain avenues of development, which it now appears that the truck will follow in the next few years.

Left-hand drive has gained much ground since last year's show. It is noteworthy that on the newer designs brought out by makers who have been in this field for several years or more, have left steer with center control, making for easy access on either side of the car, a small feature but nevertheless one which involves the time-saving element.

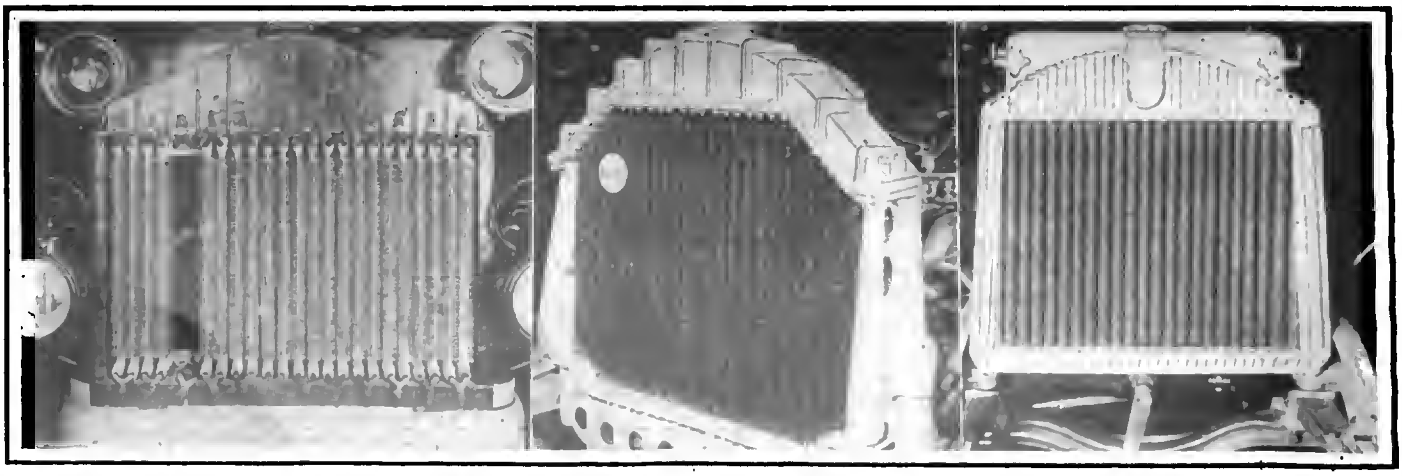
Among the new cars or new models which show this tendency toward left drive are the White 5-ton, the Kelly 1 and 3-ton machines, the Kissel 2,500-pound type, the 1.5-ton Reo, the new Mack of the same capacity, the new Universal, the Pope-Hartford new 1.5 and 5-ton creations and a number of others. On the new 5-ton Packard right drive and control are retained, these commercial vehicles being consistently opposite in driving control from their pleasure car mates, which are now all left drive.

Several machines are in evidence with hoods of the Renault type, radiators being placed at the rear of motors. Among these may be mentioned the Kelly, Walter-Latil, Lippard-Stewart, Krebs and Stewart. Two Universals, though fitted with radiators at the rear of the power plants do not use sloping hoods and should not be properly classed among the Renault types of design.

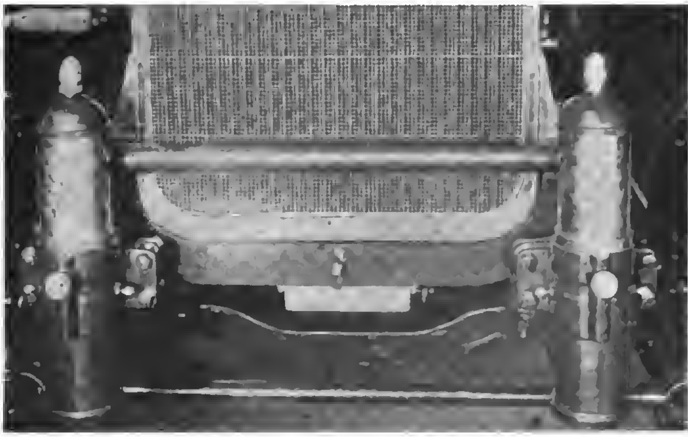
Engine starters have not gained much headway so far as commercial vehicles are concerned, their conspicuous absence on the commercial products being in striking contrast to the almost general use of some sort of cranking device on the pleasure vehicles exhibited last week. There is a general feeling among the truck makers that the starter for commercials must come if public sentiment along this line continues as it has for some time. There are a number of the exhibitors, however, who can see no use whatever for the starting device on the truck, since there is no great consideration of comfort to dictate the practice. "If the truck driver is to be set on a pedestal and humored to such an extent that he can sit back in his leather-cushioned seat and never have to crank his motor, he is too good to be a truck driver," said one exhibitor. Others advanced the argument that the increased cost to the truck buyer of putting on a starter does not pay in amount of fuel saved by shutting off the motor at each stop for the interest on the increased money invested. There are still others who do not believe there is any saving at all in stopping the gasoline motor every time a short stop is made as in package delivery service. The amount of fuel needed for starting is greater than would be that used were the engine throttled to low speed and left to run at these stops. The Krebs and the Schacht are the makes conspicuous for the use of starting devices this year.

The relative positions of the various methods of power transmission to the rear wheels remains about the same as last year. There are eleven makes which have shaft drive, that is, Studebaker, Mais, Buick, Lippard-Stewart, Brown, Maccar, Rowe (optional), Hupmobile, Autocar and smaller White models. Save for the five makes which have worm drive the remainder of the fifty-nine have jackshaft and side chains. In most instances the shaft driving through bevel gears is confined to cars of lighter capacity, the larger trucks quite generally adhering to the jackshaft construction, as heretofore.

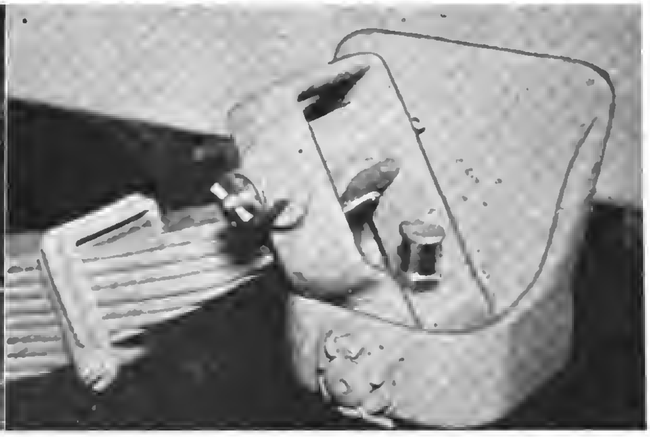
Worm drive holds its own. The Pierce models, which are exclusively 5-ton designs, have practically the same worm-drive



Three types of demountable radiator construction for truck work. Left to right—Reo, Kissel and Universal



Showing the Westinghouse shock-absorber at the front of one of the Walter models



Kelly substantial spring shackle which is provided with grease cups at both bearing points

constructional details as formerly. The new Universal 1-ton appears as a worm-driven type; four of the Blair models are so designed; two A. O. Smiths continue to carry their characteristic features; the Rowe models may be optionally supplied with worm propulsion. Most of these worms are of the overhead type, which, though open to the criticism that their oiling is somewhat less effective than that of the underneath worm design, nevertheless reduce the driveshaft angle and increase the road clearance. Schacht and Krebs are worm-driven types.

Chain covers are still somewhat in vogue, although not favored by a number of makers. The Knox and the Locomobile are examples of clean, substantial and easily removable types.

Several designs of sectional radiators have appeared. Among these are the new Reo, Kissel, the Vulcan and the Universal. The latter two employ types with separate tops, and while this is also true of the Reo, it makes use of separate tubes as well. These sections are mounted vertically, one crow's-foot clamps holding each two tubes at top and bottom.

It is a noticeable fact that the majority of the makers are equipping their cars with sealed governors, which are regulated to maximum speeds dependent upon the truck capacity as recommended by the N. A. A. M. It has been found that most makers favor these recommendations. The N. A. A. M. standard warranty plate is also much in evidence. This relates to load capacity, body weight and speed.

The National Association's recommendation that the mechanism of the truck be so arranged as not to come above the level of the frame members also appears to have been fruitful, for several makers who last year had brake rods, equalizer rods, cross pieces and grease cups above the frame level, have put them below. The object of this is so that any type of body may be accommodated.

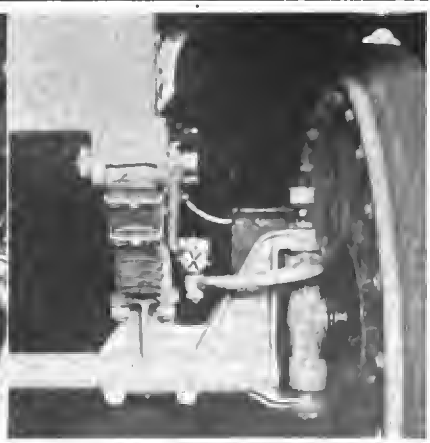
Supplementary springs are much more prominent for larger sizes of trucks than they were last year. These take several forms, the predominating designs being either cross types, which come into play only when the frame is considerably compressed, or coiled varieties fastened on the rear axle. A number of cars are fitted with rubber bumpers, which are also attached to the axles.

Steel wheels do not appear to be making much headway, only a few makes exhibiting machines so equipped. This seems rather unaccountable inasmuch as the steel wheel is somewhat lighter than the wood type of the same carrying capacity. There seems to be a general impression, however, that the metal wheel tends to greater vibration and has less shock absorbing qualities. The Locomobile trucks appear with steel wheels, as do the A. O. Smith and the Grand Rapids makes. White is exhibiting several models so equipped as well as those with wood wheels.

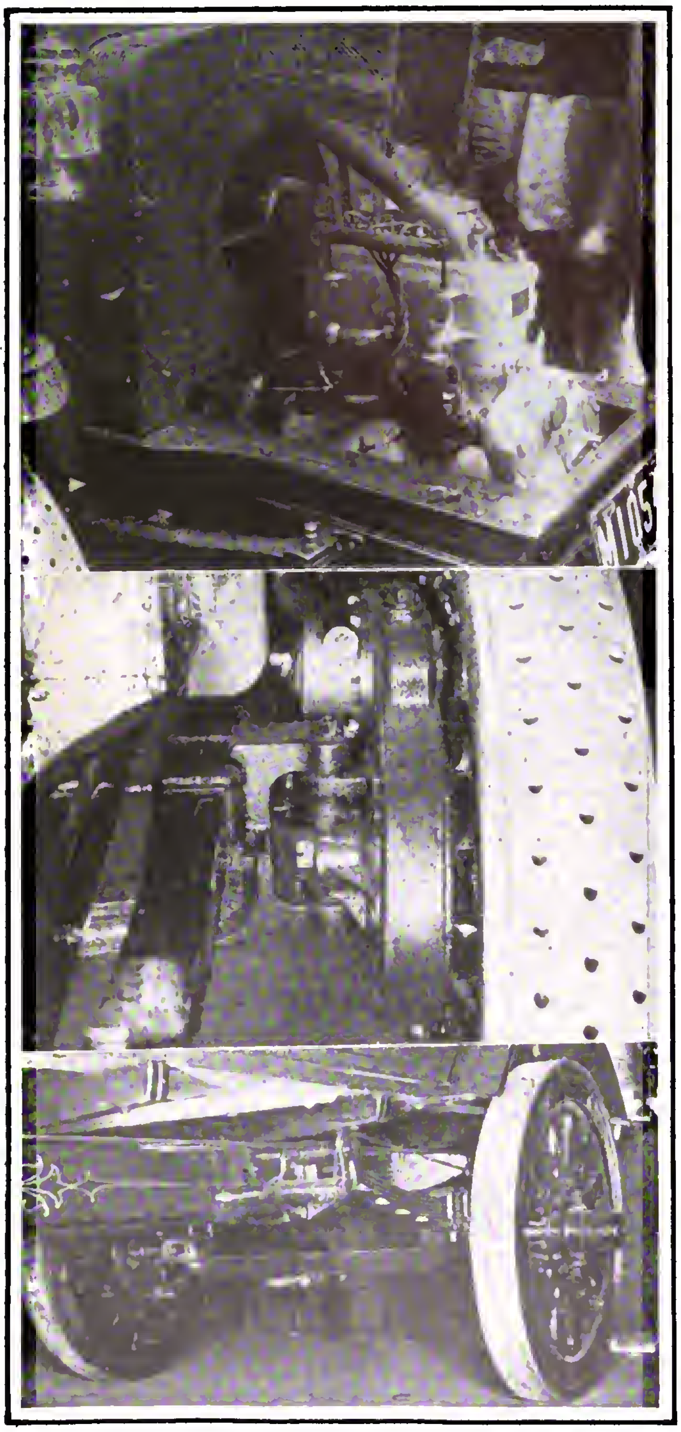
Speaking from the standpoint of cars on view the motor-under-the-hood type of design is favored as compared with the type which places the power plant under the seat. Four makers show designs of both varieties, while there are eleven of the under-seat construction and twenty-seven having the drivers position back of the motor. Notable adherents to the latter position are the Packard, Pierce-Arrow, Peerless, White, Saurer, Kissel, Selden, Velie, Atterbury, Studebaker, Smith, Service, Stegeman and a number of others. Garford, Alco, Pope-Hartford, Buick, Locomobile, Speedwell, Lauth-Juergens, Steinberg, Blair and Sanford makes use the motor under-seat design. General Motors, Knox, Mack and Universal will furnish machines of either type.

Protection for the driver has not been overlooked this year. Many cars are equipped with well-designed cabs, some completely inclosed, some with stationary tops and others with fold-

Two views of Lauth-Juergens auxiliary conically wound springs.



Reo front axle, showing integral yoke and spring seat ing tops. Windshields for these machines have not been lost sight of and take several forms. In the Garford models the glass front is hinged to the top of the cab and may be swung up and fastened out of the way when desired. Other types may be quickly removed or folded sectionally. A good arrangement for seats is shown in the Knox cab, there being a partition or arm between that portion of the seat allotted to the driver and the remainder of it which is intended for his helpers. Such a seat makes it impossible for the driver's quarters to be crowded by other occupants of the seat, and is a safety feature in that it gives the driver plenty of room for manipulation of his pedals and levers.



The Latil motor mounted in the front drive car of this name which is exhibited by the Walter Company. The design is to be manufactured by Walter under royalty. It is a French product. The radiator is mounted at the rear with the fan at its center. The center view shows the housing for the driving gears, and the shaft connection from the differential under the motor. The wheel gear bolts to the front wheel. Gears are of the spur type. Lower view—Clean-cut appearance of the underneath part of the Latil truck. Note the use of steel-tired wheels at the rear. This is a foreign tendency

Dumping bodies are also very much in evidence, a number of the foremost makers exhibiting them. These appear either as power-operated types or for hand manipulation. Noticeable among the power-operated type are the Packard, Alco, Locomobile, G. M. C., Mack, White, Pierce and Peerless, while Speedwell, Kissel, Universal, Garford and Knox favor the hand-operated body judging from their exhibits.

The A. O. Smith Company has discontinued its 3-ton chassis brought out last spring and now builds 3.5 and 6-ton models, both identical in design with their predecessor and characterized by worm-driven rear axle and a gearbox in which herringbone gears take the place of spur types and in which individual clutches are used for speed changes. The entire set of gears attaches to the cover of the gearbox, giving a readily-removable arrangement. This is one of the few companies to use steel wheels, other concerns using them being White and Locomobile. The company offers an option in wheelbases, a practise followed by a majority of the truck makers, due to the bulk of different commodities. Coal and sand call for a much shorter wheelbase than furniture. The standard wheelbase on the 3.5-ton model is 168 inches and the options are 144 and 190 inches. On the 6-ton vehicle the same measurements are used.

The question of most satisfactory wheelbases is a difficult one to solve and so not a few makers give a standard and announce maximum and minimum measurements and give any desired lengths between these extremes. In truck designs like the White, new Studebaker, etc., the different capacity bodies can be accommodated by cutting off the overhang of the frame side members. In other trucks the alteration calls for longer side members. Lauth-Juergens, on its four models, gives a standard length on each with options of 10 inches under or over this standard. For its 1, 2, 3 and 5-ton trucks the standard wheelbases measure 110, 120, 120 and 140 inches respectively.

On the 3-4 and 5-6-ton Studebakers the standard wheelbase measurement is 144 inches. The Durable-Dayton gives wheelbase options ranging from 16 to 20 inches above standard. On light delivery wagons, such as the Stewart and others in its class, it is customary not to give any wheelbase option, as the body fitted has generally capacity adequate for the different industries in which it may operate.

The majority of manufacturers have been giving careful attention to the distribution of useful load weight over rear and front wheels. These ratios vary considerably depending on whether the truck is a motor-under-the-hood type or one of the motor-under-seat type. In the motor-under-the-hood design generally 75 or 80 per cent. of the useful load is supported by the rear wheels and from 20 to 25 per cent. over the front wheels. On the other hand, where the motor is mounted under the seats, or between the seats, there is not so much overhang and the load distribution varies to 35 per cent. on front and 65 per cent. in rear. Makers are now fitting tires and springs to meet the conditions that the truck design imposes.

Makers are more conservative than ever before in the speed rating of their different machines and gear ratios between the motor and rear wheels are not only suited to the demands of the industry in which the truck operates, but also to the topography of the city or country in which it works. One maker listing four truck models gives different speds for different cities as follows and then again varies these in each city according to the nature of the work:

Truck capacity	Chicago M.P.H.	Cincinnati M.P.H.	Pittsburgh M.P.H.
1.5 tons	15	14	12
2.5 tons	14	13	11
3.5 tons	13	12	10
5 tons	12	11	8

When the entire truck industry is taken into consideration it is seen that the makers are yet far from having agreed upon any definite speed for different capacities. This is largely due to differences in design.

High Cost of Fuel Arouses Consumers

Concerted Action Contemplated in Manhattan To Cope With the Present Soaring Price of Gasoline

Statement Issued by Oil Refiners Defending Demands—New York Garage Association to Act

NEW YORK automobilists and garage owners are up in arms over the threatened increase in price of gasoline. It is probable that a campaign against the rise will be instituted when the New York Garage Association holds its annual dinner on January 28. At this dinner the proprietors of the large garages of the country will be present and ways and means for coping with the situation will be discussed. Many private citizens have signified their intention to co-operate with the garage men in the movement.

The present price of fuel in this city, Boston and other large centers is 22 cents a gallon retail for quantities less than 5 gallons, and 20 cents a gallon in amounts between 5 and 25 gallons. For quantities above 25 gallons, the wholesale figure of 17 cents prevails. This brings the price which the garage man asks somewhere in the neighborhood of 25 cents a gallon.

In a statement issued yesterday by Collins, Armstrong & Co. based on data compiled by Texas Company, the price of gasoline is discussed as follows:

"The advance in price of gasoline has brought up a great many times the question as to the reasons for it and the future supply. This question is being continually asked by motor owners, garage men, manufacturers and others interested in the motor business. It is, consequently, advisable that all salesmen should study the following items which show the conditions which pertain at the present times in respect to the motor fuel business.

"The total production of crude oil in the year 1911 was 220,000,000 barrels.

"The total production in the year 1912, as far as this can be gathered from reports at the present, will be somewhat less.

"The total production for the year 1910 was approximately 200,000,000 barrels.

"Only a certain proportion of this supply produces any commercial quantity of gasoline. The gasoline producing crudes in 1910 figured 126,000,000 barrels; in 1911, 127,000,000, and in 1912, 124,000,000 approximately.

"In 1910 there were 300,000 cars in service; in 1911, 550,000; in 1912 nearly 900,000, and it is expected that 1913 will bring this up to 1,400,000.

"In addition to the cars, there were in service in 1912 35,000 motor trucks, 75,000 motor cycles and 100,000 motor boats.

"These figures do not include the enormous number of stationary gasoline engines of small size for farm and country use which have been put in the market in the last two or three years.

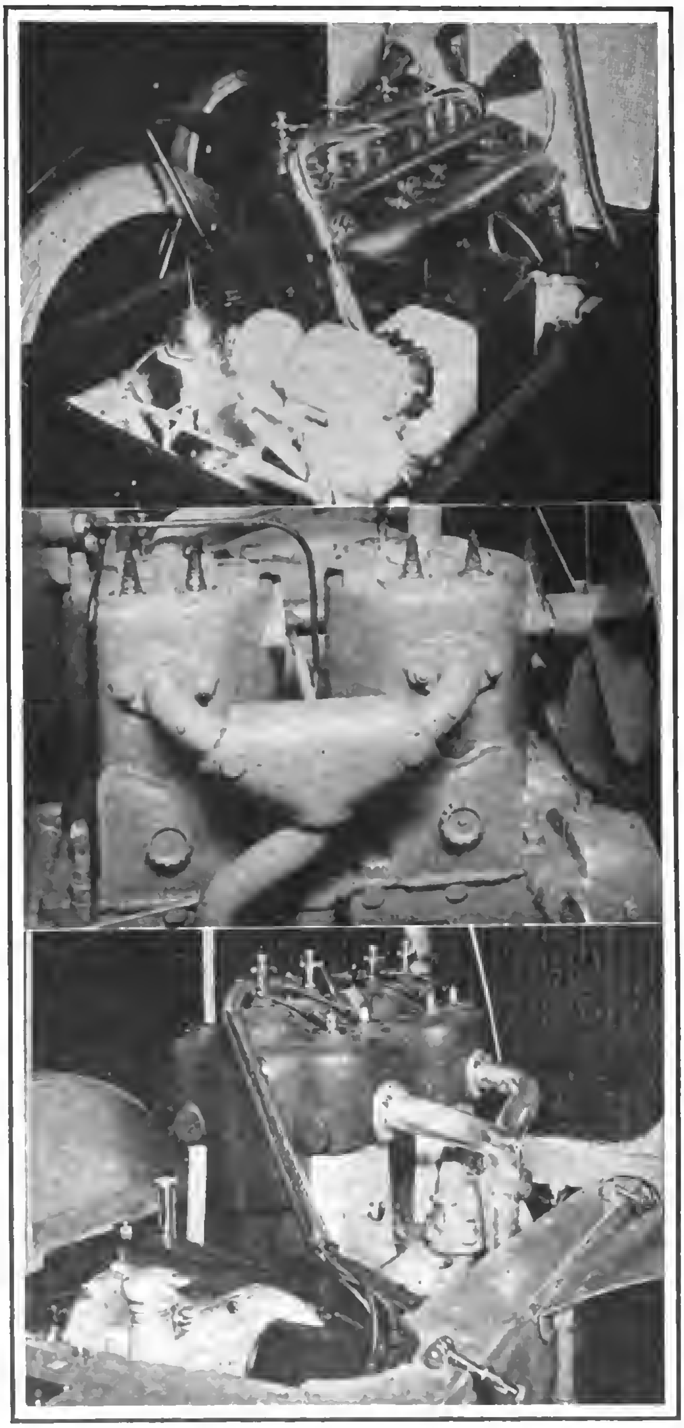
"In other words, the supply of gasoline is fixed or slightly declining, while the demand for the same is increasing with great rapidity. As a consequence of this, gasoline is increasing in value. Even at the increased price, however, the cost of gasoline is only a very small part of the cost of operating a car.

"Suppose a car runs 5,000 miles in the year and uses 500 gallons of gasoline, an increase of 5 cents per gallon would only mean $25 for the year. A small increase in the price of the tire or some of the other items which enter into the running of a car would mount up to a very much larger sum in the total operation of the year.

"Further, it might be advisable to note that the price of rubber, on account of the extensive use in the motor industry, has advanced enormously in the last few years, and there is no reason for the advance of rubber which does not apply to the advance of gasoline.

"In the production of gasoline for the market, it is necessary to drill deep wells with the certainty that at least seven out of ten of the wells which are drilled will yield nothing and be a dead loss.

"Then it must be pumped out of the well, gathered into expensive tankage, shipped through hundreds of miles of pipe lines, with expensive pumping stations every fifty or sixty miles; put through the refinery, distilled, cleaned, deodorized; shipped by tank car, tank steamer, etc., to distributing terminals, where again it must be stored in expensive tankage, rehandled, put in drums for wagon delivery or reshipped to smaller distributing stations; again tanked, rehandled and delivered by tank wagon—and for all these operations we cannot secure but a few cents a gallon more than the man does for the water, without a great deal of grumbling on the part of the consumer."



Top—View of the motor and electrical equipment of one of the new Krebs trucks. Middle—The Studebaker engine design. This motor is water cooled and the cylinders are compactly cast in pairs. Note the peculiar manifold construction. The valve springs and rods are inclosed by the easily removable covered plates provided with hand screws. Bottom—Power plant of the Kelly commercial car, showing the T-head motor construction with inclosed valves. The rear support of the motor is arched and the crankcase is slung beneath it. The wiring is carried in a tube which passes along the top of the cylinders to the back of the motor as shown

Columbus Buggy Receiver

Daniel McLarin Named—Valentine & Co. Allege Assets of $1,000,000 and Liabilities Approximating $600,000

Has Preferred Stock to the Amount of $1,300,000 and Common Stock to the Amount of $300,000

COLUMBUS, O., Jan. 20—Upon application of Valentine & Company, dealers in oils and varnishes, New York, Daniel McLarin was named receiver for the Columbus Buggy Company, of Columbus, by Judge Slater in the United States Court January 18. Mr. McLarin took charge of the large plant of the concern, located on Dublin avenue, almost immediately and announced that no let-up in operations would take place. In the petition Valentine & Company allege assets of $1,100,000 and liabilities approximating $600,000.

The Columbus Buggy Company was a reorganization of a concern of the same name which has operated a carriage factory in the Buckeye Capital for more than a quarter of a century. C. D. Firestone is president; C. E. Firestone, secretary; J. F. Firestone, vice-president, and O. H. Perry, treasurer. It has preferred stock to the amount of $1,300,000 and common stock to the amount of $300,000.

It is alleged that many of the debts of the company are overdue and threats of litigation have seriously impaired the credit of the concern. This, it is alleged, has endangered the creditors' claims and a receiver was believed necessary. It is stated that vehicles, both horse-drawn and automobiles, to the number of 100 are being built and contracted for which will amount to about $1,250,000. Stockholders are expecting a reorganization.

Automobile Securities Quotations

The week brought few developments in the automobile stocks traded at the Exchange. The most noteworthy change was the advance made by Consolidated Rubber, both common and preferred rising 5 points. Miller, Goodyear and Rubber Goods Manufacturing were likewise strong. Alco and Lozier closed slightly below last week's figures.

Michigan Magneto Company Bankrupt

DETROIT, MICH., Jan. 20—The Michigan Magneto Company, 117 Bagley avenue, has filed a voluntary petition in bankruptcy in the United States District Court at Detroit. Upon petition of the Stackpole Battery Company, of Pittsburgh, Pa., Judge Arthur J. Tuttle has appointed Charles C. Simons receiver with orders to sell the property of the company January 30 at 10 o'clock in the morning. Simons' bond as receiver has been fixed at $5,000.

In its petition to be declared bankrupt the company set up that it owes debts which it is unable to pay in full and that it is willing to surrender such property as is not exempt under the bankruptcy laws for the benefit of its creditors. Its debts include $44.73 as taxes due the city of Detroit, and $135.17 as wages due employes. The liabilities are given as $31,050.26 and the assets as $28,415.85.

In the list of unsecured creditors appears the name of the J. S. Bretz Company, of New York, $5,027.25 (notes) and the Reo Motor Car Company, of Lansing, Mich., $800 (notes). In the schedule of assets, the company lists machinery, office fixtures, dies, etc., the petition stating that the figures given in the schedule were the cost prices, that the machinery has been used a long time, that the merchandise is special material of no market value, as also are the patterns and dies. Certain of the machinery, the company sets up, is owned on title contracts on which a balance is yet unpaid. The company declares that outside of the list of assets given there are assets totaling $7,902.05, of which the greater portion is doubtful or uncollectable.

To Organize New Tire Company

AKRON, O., Jan. 18—What is to be known as the Mohawk Rubber Company, with a capitalization of $350,000 is to be organized in a few days. Of this amount $250,000 will be common stock and $100,000 7 per cent. cumulative preferred stock. Organizers of the new company are: R. M. Pillmore, J. K. Williams and S. S. Miller.

The new company will purchase the real estate, buildings, machinery and plant of the Stein Double Cushion Tire Company, located in East Akron, which consist of about 2.5 acres of land, a factory, switching facilities, etc., having a capacity of from 75 to 100 tires per day. This plant can be put in condition within 60 days to produce a daily output of from 75 to 100 automobile tires.

For this property the new company will pay the Stein Double Cushion Tire Company the sum of $7,500, three-fourths of which amount is to be paid in the stock of the new company at par and one-fourth cash.

Findlay Factory Sold for $50,000

FINDLAY, O., Jan. 18—The Findlay Motor Company plant was sold Thursday to J. G. Cleary, of Milwaukee, Wis., for $50,000. The sale was made under orders from the United States Court at Toledo, and sold for just the price the court stated should be the lowest bid that could be accepted. The company was promoted by L. E. Ewing, of Cleveland, who secured $100,000 of local capital. The company has been in the hands of John M. Barr, as receiver, since September 19, 1911.

It is the intention of Mr. Cleary to dismantle the plant and remove the machinery to Milwaukee, Wis., where it will be used in other industries.

Day Company Elects Officers

DETROIT, MICH., Jan. 18—At the annual meeting of the Day Automobile Company the following officers were elected: President, Thomas W. Day; director and factory manager, A. W. A. Bartlett; secretary, William S. Power; treasurer, John E. Murphy; director, William J. Emery.

Stewart-Warner Preferred Issued

The Stewart-Warner Speedometer Corporation which was recently formed by the combination of the Stewart and Clark Manufacturing Company and the Warner Instrument Company and which has a total capitalization of $11,000,000, has decided to offer $1,000,000 preferred stock to the public through White, Weld & Company, New York, Chicago and Boston brokers. The remaining $10,000,000 is common stock and is not being issued for the present, but it is very probable that the spring will see an offering to the public of the common stock as well.

The stock offered is a 7 per cent. preferred and the dividend is payable quarterly, on the first days of February, May, August and November, respectively. Three years after issue the stock which is offered at par is redeemable as a whole or in part at 110 and accrued dividend. In connection with the announcement of the stock, J. K. Stewart, president of the corporation, gave out a statement of the business done by the now affiliated companies during the past 4 years. The earnings of both companies aggregated $3,200,000 for this time, the net earnings for the fiscal year ending October 31, 1912 being $925,000. The annual dividend of both companies combined amounted to $70,000.

Easier Tone in the Rubber Market

The easier tone which developed in the world's leading crude rubber markets on Monday was still in evidence yesterday, and the reactionary tendency made further progress on both sides of the water. The demand from manufacturers at home and abroad failed to show any expansion, and, with prices weakening, consumers, it is contended, will be averse to purchasing in any other than a hand-to-mouth fashion. In London the trend of prices was downward throughout the session, though in the absence of any marked pressure to sell the net change in quotations was comparatively small. Aside from the easier tone which prevailed, the situation here underwent no change, the price remaining at $1.06 a pound.

Peerless Declares Stock Dividend

A substantial stock dividend, payable out of the surplus in the common stock of the company, has been declared by directors of the Peerless Motor Car Company, Cleveland, O. This action follows the announcement of an increase in capital stock which enables the Peerless company to provide for the rapid extension of the business.

The company starts the new year with a paid-in capital stock of $4,200,000 and assets, after deducting all liabilities of every kind, of between $5,000,000 and $6,000,000, exclusive of patents, trade marks and good will.

Michigan Company Changes Name

The name of the Michigan Automobile Company, Ltd., Kalamazoo, Mich., has been changed to Fuller & Sons Manufacturing Company. This change was desirable on account of the confusion existing due to the recent incorporation of the Michigan Motor Car Company of the same city which is owned by the Michigan Buggy Company.

F. D. Fuller retains the presidency of the new company, which position he has held ever since the Michigan Automobile Company was incorporated 10 years ago. L. C. Fuller is secretary and treasurer, while W. P. Fuller is sales manager. The capital stock of the concern is $100,000.

DETROIT, MICH., Jan. 20—Fire of unknown origin January 17 destroyed the brass and aluminum foundry of the Buick company, at Flint, with a loss estimated at $50,000. The foundry will be rebuilt at once and only a few men will be laid off temporarily. The loss of the foundry will not hamper the Buick plant to any extent as enough castings are on hand to run the plant until arrangements can be made for getting more.

Stockholders of Seitz Automobile Transmission Company Purchase Everything Except Buildings and Machinery

Will Begin Operations in Separate Plant at Wyandotte, Mich.—Samuel Winternitz & Company Buy Assets

DETROIT, MICH., Jan. 20—Stockholders of the Seitz Automobile Transmission Company, Wyandotte, Mich., have purchased the property of the bankrupt Grabowsky Power Wagon Company, of Detroit, with the exception of the buildings and machinery, and began operations in a separate plant at Wyandotte, January 20. The Wyandotte plant is to manufacture the Grabowsky truck. The Seitz company officers are to resign and the company is to be reorganized to become successor to the Grabowsky company.

For the present George A. Horner, who has been manager of the Grabowsky Detroit plant for the creditors, will be general manager of the Grabowsky plant at Wyandotte, in which the Grabowsky trucks will be manufactured.

The sale of the assets to the Seitz stockholders was made by Referee Lee Joslyn, of the bankruptcy department of the United States court at Detroit and the sale has been confirmed. The assets not covered in the Seitz transaction were purchased by Samuel Winternitz & Company, of Chicago.

SYRACUSE, N. Y., Jan. 18—The United States Tire Company has selected this city as the home of one of its sub-branches. It is at 696 S. Salina street and George A. Fish, heretofore connected with the Hartford branch, is in charge.

Market Changes for the Week

The gradual decline in price of tin was the most important market change of the week; starting at $51.10 on Wednesday and falling to $50.25 yesterday, a loss of $.85. Raw silk from Italy and Japan suffered and gained respectively, that from Italy $.05, and from Japan $.02 1-2. Domestic scrap rubber remained in a steady position throughout the week, collections still reported to be light and stocks are apparently small. A moderate inquiry is being received from domestic reclaimers and fairly large shipments are being made abroad.

Complaint Discussed in Rose Patent Suit

Court Rules Design Patents on Which Infringement Was Charged Are Both Invalid

Batavia Tire Serves Notice of Infringement—Receivership for Searchlight—Petition Against Randolph

A DECISION rendered in the United States District Court for the District of New Jersey by Judge Cross in the suit of the Rose Manufacturing Company vs. the E. A. Whitehouse Manufacturing Company and the Le Compte Manufacturing Company dismissed the bill of complaint with costs. The bill alleged infringement of the Rosenbluth and Hughes patents owned by the Rose company by the defendants. The decision:

"There are four patents involved in this suit, two of which are mechanical patents and two design patents. The bill of complaint alleges that they are all owned by the complainant and have all been infringed by the defendants. The defendants not only deny this, but deny their validity. The mechanical patents are Nos. 883,973, issued April 7, 1908, to one E. M. Rosenbluth, for a lamp bracket, and No. 962,220, issued June 21, 1910, to one W. B. Hughes, for a number-plate support for vehicles. The design patents were both issued to E. M. Rosenbluth May 16, 1911, for vehicle number-plate supports and another, respectively, 41,388 and 41,389 * * *

"In behalf of the defendants, it is strenuously argued that this patent is invalid for various reasons, but especially in view of the prior art. It is quite apparent that if it discloses invention, it is of a low order. Briefly stated, the device consists of a bracket, comprising a base, by which it may be affixed to an automobile or other vehicle, and two arms, one of which carried a number plate or sign and the other a lamp, whereby the plate or sign may be illuminated when desired. These arms are made relatively adjustable with each other. * * *

"It is hard to understand why a problem of that character should have proved knotty, if it did, in the first instance; but, however, that may have been, all difficulty was resolved, when Rosenbluth undertook its solution, by the teachings of the prior art which showed similar devices of various kinds; for instance, a bracket attached to a bed, one arm of which carried a table and the other a lamp which illuminated the table. * * *

"The idea embodied in the patent under consideration, taken by itself, is of the simplest character and of questionable patent ability, but when in addition to that fact the prior art, in analogous matters, is considered, it becomes manifest that the attempt further to dilute this simple idea and then protect it by means of a patent, should not be fostered. Rosenbluth, giving him the utmost credit to which he is entitled, merely what was simple and old and common-place in analogous arts and applied it to a new use. Everything that he did had already been done in substantially the same way, although the device had not been applied to an automobile. * * *

"The patent to Hughes, claims 5 and 6 of which are in controversy, shows no patentable advance upon Rosenbluth, hence whether that patent were valid or invalid, the one to Hughes could not be upheld. Rosenbluth's patent of itself would defeat it. * * *

"The design patents are both invalid. The statute authorizes the issue of such a patent under certain conditions, to 'any person who has invented any new, original and ornamental design for an article of manufacture.'"

Batavia Serves Infringement Notices

The following notification was served by the Batavia Rubber Company, Batavia, N. Y., through its attorneys, Holmes, Rogers and Carpenter, on the Seamless Rubber Company, New York City; the Kelley-Racine Rubber Company, Racine, Wis.; United & Globe Rubber Manufacturing Companies, Trenton, N. J.; Stein Laplock Tire Company, New York City; C. H. Stoddard Rubber Tire Works, Rochester, Mass.:

"You are hereby notified that you are infringing upon the rights of the Batavia Rubber Company in the making of a non-skid tire which is so close an imitation of the 'Security' non-skid tire, which has been made by the Batavia Rubber Company for many years, as to deceive purchasers seeking Batavia tires, and you will be held accountable by suits at law for any damages.

"We will wait a reasonable time for your notification that you will cease further infringement."

Friendly Receivership for Searchlight

CHICAGO, ILL., Jan. 20—Friendly receivership has been adopted as a means of complete reorganization by the Searchlight Gas Company, Warren, O., whose general offices are in Chicago. At the petition of the Continental and Commercial National Bank of Chicago, Horace B. Pearson was appointed receiver by United States Judge William L. Day. The bank appraises the liabilities of the company at $200,000, a part of which is in notes due, and assets to the amount of $400,000, not all of which is available for immediate conversion into cash.

The present financial condition is not one of insolvency, but of temporary embarrassment, and is attributed by the receiver to the service expansion that has been carried on by the concern in such volume as to exceed the adequacy of the capital of the company. As the maintenance of service stations is one of the principal essentials of the business, this expansion is regarded as indispensable to the welfare of the business, it is thought that a general rehabilitation of the financial condition of the company will be beneficial. The receiver will continue active business.

Petition Filed Against Randolph Company

CHICAGO, ILL., Jan. 20—Proceedings in involuntary bankruptcy have been instigated, involving the Randolph Motor Car Company, Chicago, and Flint, Mich., a corporation of Delaware. The petition was filed January 3 by the Mercantile Printing Company, Charles Cramer, C. Klare, and one Robyn, the last three commission salesmen; it was recorded January 8. The Central Trust Company, of Chicago, was appointed receiver for the district of Illinois and southern Michigan.

Knox Company to Reorganize

SPRINGFIELD, MASS.—(*Special Telegram*)—The Knox Automobile Company of this city, which has been operating under a trusteeship for the past 4 months, due to technicalities caused by the death of the late A. N. Mayo, treasurer of the company, is at present on the eve of reorganization with increased capital, and when such is completed will be known as the Knox Motor Car Company. Sufficient new capital is already subscribed to make it possible for the concern to largely increase its output and to further facilitate this the number of passenger car models will be reduced and their output proportionately increased.

In order to achieve the formation of the Knox Motor Car Company it will be necessary to undergo formal bankruptcy proceedings, during which, however, it will not be necessary to cease manufacturing operations.

Chain Grip Injunctions Granted

On January 17 the United States District Court, Southern District of New York, issued an order enjoining the W. E. Pruden Hardware Company, of New York City, from selling unlicensed cross chains, cross chain hooks, side chains, side chain hooks and other parts adapted and intended for use in the manufacture and repair of tire chain grips. The suit had been brought by the Wood Chain Tire Grip Company, New York City, under the Parsons patent No. 723,299.

Judge Lacombe, of the above-mentioned court, issued an order the same day enjoining the Q. D. Hook Company, Edwin S. Holmes, Jr., Randolph T. Warwick, Charles Bauer and Leon Tobiner from making and selling the Q. D. cross chain hook, made under a patent of Edwin S. Holmes, Jr.

M. & A. M. Elects Officers

At the tenth annual meeting of the Motor and Accessory Manufacturers, held at the Waldorf-Astoria, January 15, at 5:30 p. m., there was a very representative attendance of members. In addition to the reading of the reports by the retiring president, treasurer and chairmen of the various committees, the following were elected as members of the board of directors, to serve 3 years: C. E. Thompson, of the Electric Welding Products Company; Alfred P. Sloan, Jr., of the Hyatt Roller Bearing Company; F. Hallett Lovell, Jr., of the Lovell-McConnell Manufacturing Company, and C. E. Whitney, of the Whitney Manufacturing Company.

These gentlemen succeeded the following, whose terms expired:

D. J. Post, Veeder Manufacturing Company; H. W. Chapin, Brown-Lipe-Capin Company; C. T. Byrne, Byrne, Kingston & Company, and C. E. Whitney, Whitney Manufacturing Company.

At the meeting of the board of directors, held in the headquarters on January 16, the following officers were elected to serve for the ensuing year: President, J. H. Foster, Hydraulic Pressed Steel Company; first vice-president, F. Hallett, Lovell, Jr., Lovell-McConnell Manufacturing Company; second vice-president, C. E. Whitney, Whitney Manufacturing Company; third vice-president, F. C. Billings, Billings and Spencer Company; treasurer, L. M. Wainwright, Diamond Chain & Manufacturing Company; secretary and assistant treasurer, Alfred P. Sloan, Jr., the Hyatt Roller Bearing Company. William M. Sweet continues as manager.

Maryland Owners Must Pay D. C. Fee

WASHINGTON, D. C., Jan. 18—After having contributed more than $50,000 to the coffers of Maryland for the privilege of using Maryland roads, the automobile owners of the District of Columbia have at last been abled to retaliate for the alleged bad treatment they have been subjected to for several years. The district commissioners have adopted new regulations, which will become effective February 1 next, compelling all Maryland motor car owners to pay a license fee to the district equivalent to the fee which they pay the state, in complete disregard of the fact that Virginia, Pennsylvania and, in fact all other states that grant reciprocity, can have the motor cars of the citizens of those states enter the District of Columbia without the payment of any license fee and despite the further fact that the district license is only $2 and is perpetual.

In other words, Maryland motor car owners must pay the same license fees exacted of residents of the state.

Emise Motor Car Company Formed

Several members of the old Lozier Motor Company organization and one or two who are at present connected with the concern have organized a company to manufacture a counterpart of the present Lozier light six under the name of the Emise Motor Car Company. It is understood that the company will be formed in Cleveland, O., and that the car will be made to sell at a figure below $2,000. Officers of the new company will include: C. A. Emise, former sales manager of the Lozier company; Sam Regar, former treasurer; W. S. Mead, former sales manager of the New York Lozier branch, and F. C. Chandier, former second vice-president to the Lozier company. The engineer will be T. V. Whitback. Organization plans contemplate the manufacture of about 5,000 machines for the coming year.

Alleges Sparton Infringement

The Lovell-McConnell Manufacturing Company, Newark, N. J., is suing the Jackson Eastern Distributers, Haynes Automobile Company and Garland Auto Company, all of New York City, alleging infringement of the Klaxon patents by the use of the Sparton horn. The first company has also filed suit against the Sparks-Withington Company, Jackson, Mich., maker of this horn.

N. A. A. M. Versus Tire Fillers

The National Association of Automobile Manufacturers on January 8 passed the following resolution:

"That members of this association will withdraw from their warranty all cars in whose pneumatic tires there has been any substitution for the usual air cushion."

Horn Decision Upheld By Court of Appeals

Lovell-McConnell Alleges That International Automobile League Is Selling Horns for Less Than Retail Price

Lower Court Grants Certain Prayers for Preliminary Injunction But Denies Others

JUDGE LACOMBE, of the United States Circuit Court of Appeals, Second Circuit, New York, in the suit of Lovell-McConnell Manufacturing Company, of Newark, N. J., *vs.* the International Automobile League, of Buffalo, N. Y., has rendered an opinion upholding the decision of the lower court with some modifications. The lower court granted certain of the prayers for a preliminary injunction but denied other prayers of the bill. The complainants asked for an order restraining the defendants from selling Klaxon horns for less than the retail price stated on the contract, under which the horns are sold to the distributer, as which the International Automobile League acts, so far as its members are concerned. The opinion is, in substance, as follows:

"The complainants make automobile horns (the Klaxon horn) under a patent and sell the same to dealers under a complicated form of license which, among other things, provides that the purchasers shall not resell at less than a stated price. The injunction which was issued prohibits defendants from 'selling or offering for sale, directly or indirectly, any of complainants' horns marketed and sold by complainants under their conditional licenses set forth in tags or labels upon or secured to said horns, for less than the price designated by complainants at which said horns must be sold to the public, as shown by the tags and labels secured to said horns by the complainants.'

"It is not necessary to set forth the various other preliminary injunctions which complainants now ask for, because in our opinion they are of the sort that should be considered only at final hearing, especially because complainant's theory as to this additional relief apparently is that there has been some forfeiture of license, so that the defendant is to be regarded as never having had a license and, therefore, as an infringer. Since the answer attacks the validity of the patent, which defendant may properly do if he is not a licensee, and an extensive prior art is set up, the questions raised upon this argument should be left for disposition at final hearing.

"In one particular, however, complainants are entitled to some further relief.

"The defendant is a concern operated on a membership and profit-sharing plan whereby each member is obliged to pay a membership fee of $10. It buys various automobile fittings and accessories at manufacturers' prices, and before this injunction sold these horns to its own members at a considerable abatement from the price fixed by manufacturer for sale to the public.

"After the injunction was issued it sent a circular to all its members notifying them that it could no longer sell horns to them at cut prices. The same circular included the following offer:

"'While the Klaxon people may insist upon the League charging its members the retail price, they surely cannot prevent the League giving the profits to charity. If you are insistent upon having a Klaxon send us your check for the full retail price, as given above. We will sell it at no other price. Then give us the name of two charitable institutions in your vicinity deserving of assistance, and we will select one of them and draw our check to its order for the difference between the cost to us and the retail price, forwarding the check in your care so that we may be sure it will reach its proper destination.'

"This seems to be a very flimsy device for evading obedience to the injunction against cutting prices. Most of the individuals whose condition in life is such that they can afford to own and use automobiles are presumably in the habit of making regular contributions at stated periods to one or more worthy charitable institutions. When defendant tells them that if they will buy from it Klaxon horns at the price they must pay everywhere else, it will send them a check for $8 or $9 on each horn drawn to the order of such charitable institution as they may designate, it is naturally to be expected that they will accept the offer, will take the draft, add to it sufficient to make up their usual contribution and pass the same on to the institution.

"Probably there are other persons whose charitable vision is bounded by the horizon of themselves and their individual families. It would be an easy thing for one of them to send on two fictitious titles of what seemingly are charitable institutions, but which in reality represent merely the distress produced in this family by the payment of the full list price for a Klaxon horn. Upon receiving the draft he could write the fictitious name of the payee, and then indorse, deposit and collect it in his own name. The suggestion that defendant would undertake any investigation to discover whether or not the selected 'charitable institution' is real or fictitious puts a severe strain on one's credulity. We think this devotion of the discount from list price to 'charitable institutions' is a mere evasion of the order and that the present injunction should be modified by inserting a clause which will put a stop to the practice.

"As thus modified the order is affirmed, without costs."

Grand Prix Date Fixed

On July 12 the 19-Mile Course Near Amiens Will See Fuel Consumption Contest

Indianapolis Busy Preparing Memorial Day Race—Southern Touring Course Planned

PARIS, Jan. 12—Saturday, July 12, has been fixed for the French Grand Prix fuel consumption race to be held on the 19-mile course near Amiens. It has been decided that the course will be covered twenty-nine times, which will give an approximate total distance of 563 miles. For this distance, the fuel allowance will be 40 gallons, the rules stipulating that cars shall not consume more than 1 gallon per 14.1 miles. The whole of the fuel must be on the car at the start of the race. The exact length of the course will not be known until it has been decided how the hairpin turn at the Amiens end will be treated. It is probable that instead of taking the cars around the present bend a special semi-circular banked track will be built uniting the two parallel roads. This bend will be so designed that cars can pass from the first to the second leg of the course at high speed, and as the main grandstands will be built around the outside of the banked turn, true autodrome conditions will be secured. Probably the pits will be on the straightaway just after the banked turn.

It is probable that Mercedes cars will come into the race. The English agent of the German Mercedes Company has made an entry, but this has been temporarily refused by the racing board, on the ground that only manufacturers can take part in the race. If, however, the parent company makes no objection to the agent running these cars, they will be admitted by the French Club. It is also probable that one or two Turcat-Mery cars will be entered for the Grand Prix.

Very few of the drivers have yet been selected for the race. The Peugeot team will consist of Georges Boillot, Jules Goux, and Zuccarelli. Sunbeam has decided to have two English and two French drivers. The former will be W. Lee Guinness and D. Resta, and the latter Victor Rigal and M. Caillois. Delage has selected Albert Guyot as one of his drivers; the second has not yet been appointed. Two of the Schneider drivers will be Champoiseau and Croquet, who drove for this firm last year; the third man has not been selected. Arthur Duray will probably be at the wheel of the Turcat-Mery car about to be entered. Christiaens will drive the six-cylinder Excelsior. The old time cracks Wagner and Hemery will probably sign on with some of the foreign firms.

It is now practically decided that the Grand Prix will be followed by a motorcycle and cyclecar race on the same course. The conditions for this have not yet been decided on, and no official announcement regarding the race has yet been made.

Columbus To Have 200-Mile Race

COLUMBUS, O., Jan. 18—The Columbus Automobile Club has asked for a sanction to give a race meet at the track of the Columbus Driving Association, Labor Day and committees to have charge of the arrangements will be named in the near future. It is proposed to give a 200-mile race, like the one in 1912, which was such a huge success in every way.

Only 1 Day of Racing at Speedway

INDIANAPOLIS, IND., Jan. 20—The management of the Indianapolis Motor Speedway has decided that there shall be but 1 day of racing at the May meet to be held at the Speedway. This will be on Memorial Day—May 30—and the only vent will be the 500-mile international sweepstakes for cars of 450 cubic inches piston displacement and under.

Some time ago the management contemplated a 2-day meet, with a number of shorter events for 1 day and the 500-mile race the next. After consulting with manufacturers, it has been deemed wise to limit the meet to 1 day and one event.

The Nyberg Motor Car Company, Anderson, Ind., has entered a Nyberg car for the race and has nominated Harry Endicott as driver. This makes three entries to date with prospects bright for a large number of additional entries before many days. Endicott drove a Schacht in the race last year, finishing in fifth place. The Nyberg entered has a 4-inch bore and 5-inch stroke, with a piston displacement of 389 cubic inches.

The sale of tickets for the race has opened and it is reported that the demand for seats far exceeds last year's.

Billy Knipper, of race-driving fame, will pilot a Henderson car in the Indianapolis race on Memorial Day. He is at present the Rochester, N. Y., representative of the Henderson Motor Car Company.

Bob Burman, the speed king, has signed a contract to drive a Keeton 6-48 in the 500-mile race at Indianapolis on May 30.

L. I. A. C. Run on Washington's Birthday

Members of the Long Island Automobile Club had an enjoyable time at the first smoker of the winter season on January 16, at their clubhouse in Brooklyn, N. Y. The good roads committee, A. E. Beggs, chairman, intends to begin as early as possible to place signs in the various roads in Long Island. J. Auer, chairman of the committee, announces that the first run will be to some point within a radius of 15 miles on Washington's birthday. Fourteen trophies will be competed for this year.

South to Get Touring Course

ROCKPORT, TEX., Jan. 18—With the increase in automobile touring in the Gulf coast country of Texas and Louisiana, particularly during the winter season, the idea of providing additional facilities for this pleasure has taken shape in the proposition of establishing a beach speedway that will be more than one thousand miles long. This prospective automobile touring course will start from a point on Atchafalaya Bay, on the Louisiana coast, and will run to the mouth of the Rio Grande.

Minneapolis After A. A. A. Run

MINNEAPOLIS, MINN., Jan. 18—The trustees of the automobile club of Minneapolis have voted to make formal invitation to have the 1913 A. A. A. reliability tour start in the Twin Cities. The contest committee, Dr. H. F. Marston, chairman, has been instructed to ask the Civic and Commerce Association, the aggregation of business men, to back the invitation. The state association has already had an invitation from the Black Hills motorists and commercial clubs to tour west to the Yellowstone Park through that district.

To Abate Cayuga Ferry Nuisance

SYRACUSE, N. Y., Jan. 18—Senator J. Henry Walters has successfully taken up with the State Highway Department the matter of complaints against the private ferry across the foot of Cayuga Lake on the Auburn-Cayuga state road, much used by through tourists. For several years automobilists have been forced to pay heavy charges to cross the ferry and Syracuse and other automobilists have vigorously protested. The Highway Department announces that it will improve a road making a detour and crossing the ferry will be unnecessary until a new through route now in process, is completed.

Quakers See 300 Cars

In 30,000 Square Feet, Products of Sixty-nine Factories Are Displayed at Philadelphia

Two Shows for Providence—Davenport Will Have Big Show—Baltimore's Exhibition

PHILADELPHIA, PA., Jan. 18—With no formal ceremony beyond the turning on of the switch that loosed a flood of light throughout the building, the twelfth annual Automobile Show, conducted under the auspices of the Philadelphia Automobile Trade Association, opened tonight in the new garage of the Automobile Club of Philadelphia. The exhibition will continue for a fortnight, the first week being devoted to pleasure cars, both gasoline and electric, and accessories. The second week commercial vehicles will be on view, together with a hold-over accessories display.

Three floors, each containing approximately 30,000 square feet, are given over to the display. This is far more space than has heretofore been available in both the old armories combined, but it was needed, for in the number of exhibits, variety and completeness, it is the most comprehensive and representative show ever held in Philadelphia, and if first-night attendance is any criterion it will set a mark hitherto unapproached. Notwithstanding blustery winds and a drizzling rain enthusiasts kept pouring into the show building by the hundreds, until, at its height, large as is the structure, with two huge elevators, wide stairway and roomy aisles, all avenues of progression were literally choked.

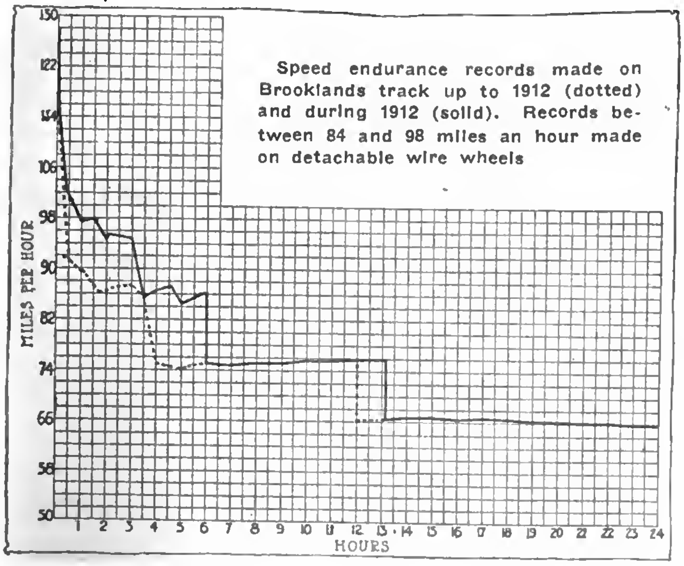
Sixty-nine separate makes of American gasoline and electric pleasure cars, showing in all about 300 automobiles, together with twenty-five accessories dealers, presenting a more varied array of motor car incidentals than has ever been assembled before in Philadelphia, comprise the exhibition.

With the exception of varying changes in body design, especially in closed car types, no radical departures in mechanical construction are apparent.

It would be difficult to conceive of a more satisfactory home for the show. Lending itself admirably to the purpose, the art of the decorator has transformed each of the three floors into bowers of beauty. Furnishing opportunities not possible in former years, advantage has been taken to make the settings of the show more elaborate. The first floor has been converted into an Italian garden, scattered about which are Venetian urns mounted with mosaic globes lined with electric lights. Overhead are streamers of leaves, caught up from pillar to pillar with ornamental wreaths. On the second floor is portrayed an autumn scene, with pergola and trellis effects, the blank wall being covered with a road scene in which the automobile occupies a conspicuous position.

On the third floor are California scenes. Overhead is sky, through which peep electric bulbs in the form of stars. Around three walls is a representation of an old Spanish wall, the fourth containing a California landscape. On each of the floors an orchestra discourses music throughout the evening. The orchestral music is varied by the interpolation of xylophone solos, vocal solos and the playing of bells, scattered around the room, from an electric keyboard.

As has been the yearly custom, one day in the week has been set apart as Society Day, on which the price of admission will be doubled, and special features will mark other days. Next Thursday will be Society Day and on Wednesday night next the 1,600 members of the Automobile Club of Philadelphia have been invited to attend the show.



Speed endurance records made on Brooklands track up to 1912 (dotted) and during 1912 (solid). Records between 84 and 98 miles an hour made on detachable wire wheels

Two Shows To Be Held at Providence

PROVIDENCE, R. I., Jan. 20—Providence, R. I., is to have two motor car shows during the week of January 25 to February 1 inclusive, according to plans that have been worked out. The one to be held by the Rhode Island Automobile Dealers' Association is to take place in the State armory.

Columbus Show Dates March 8-15

COLUMBUS, O., Jan. 18—Arrangements have been completed by the joint committee representing the Columbus Automobile Club and the Columbus Automobile Trades Association to give the annual Columbus automobile show in the Billy Sunday tabernacle, on West Goodale street for the week beginning March 8. The tabernacle, where Evangelist Sunday is holding a revival service, is one of the largest structures ever erected in the Buckeye Capital. It will give more floor space than was ever given in any previous show.

Syracuse Show in One Building

SYRACUSE, N. Y., Jan. 18—The board of directors of The Syracuse Automobile Dealers' Association has decided to confine this year's automobile show, February 25 to March 1 to the Armory, instead of holding the overflow in the Alhambra, as was done last year. There will be space for all the exhibits under one roof, owing to the fact that the part used by Troop D is to be used for the first time in addition to the portion belonging to Company C.

Davenport Show Will Be Big

DAVENPORT, IA., Jan. 18—Owing to the large demand for exhibit space the arrangements committee in charge of the annual show of the Tri-City Automobile Dealers' Association, have decided to exclude all dealers outside of the three cities. Space will be alloted this week. Preparations are being made to make the 1913 show the biggest ever held here. The Tri-City Automobile Dealers' Association was only recently incorporated for $10,000.

Forty-Nine to Show at Baltimore

BALTIMORE, MD., Jan. 20—There will be forty-nine exhibitors at the motor car show to be held in this city February 18 to 22 in Fifth Regiment Armory. These will include thirty-two pleasure car firms and seventeen commercial car dealers. The drawing for space will be held January 22.

Badgers After New Law

Signal Use, Registration and Penalties for Car Theft Among the Chief Points Proposed by State Association

Packard and Willys Give $150,000 Each for the Building of the Transcontinental Stone Road

MILWAUKEE, WIS., Jan. 17—A legislative campaign was outlined and authorized by the Wisconsin State Automobile Association at its sixth annual meeting in Milwaukee on January 15. The board of directors was directed to pursue effort to secure new laws at the hands of the Wisconsin Legislature, now sitting, on approximately the following distinct points:

a. Universal light law, requiring every vehicle in Wisconsin to carry a light at night. Now required by city of Milwaukee.

b. One registration per year per owner, instead of a registration covering the specific car owned at the time application for registration is made, so that if a man purchases a new car and disposes of his old one within any year, the old license will remain in force until January 1 next.

c. Uniform signal law, requiring all motor cars to be equipped with a distinctive warning signal peculiar to motor cars as a whole, as for instance, an electric horn with a harsh note.

d. Heavier penalities for theft of cars, for joy riders, and for chauffeurs who railroad owner's cars.

It was decided to oppose any attempt to impose a tax based on weight or horsepower; to change present laws limiting speed, or interference with any present good roads legislation which would make the movement for permanent highways less effective.

The board of directors was authorized to proceed with arrangements for the fourth annual Wisconsin reliability tour, to be conducted next July. It is intimated that the tour will be changed from an exclusively trade proposition to one for amateurs, the deed of gift of the $1,000 *Sentinel* trophy to be changed by Charles F. Pfister to make this possible.

A. B. of T. 1913 Handbook Is Out

The Handbook of Gasoline Automobiles for 1913 issued by the Automobile Board of Trade is just off the press. It is compiled in the same standard form as in previous years. The descriptions of machines therein contained are sufficiently complete for the average purpose of reference and the illustrations which accompany the specifications clearly describe the body styles of the various models. Exclusive of catalogue request blanks which are placed at the end, the book contains 187 pages of extremely useful information. There are 146 pages devoted to descriptions of pleasure cars and twenty-seven pages on gasoline trucks. In order to make comparison between different makes as simple as possible, the same form of specification is used in each case. Another point that has received attention is contained in a footnote at the bottom of each page giving the equipment that is included in the list price. In addition to the lists of officers of the A. B. of T. there are alphabetical indexes to the names of the manufacturers as well as the names of the cars. The handbook should form an invaluable *vade-mecum* for present and future reference.

First Annual Breakfast of Motor Truck Club

The first annual breakfast of the Motor Truck Club was held at George Rector's in New York City Tuesday, January 21. The attendance exceeded all expectations to such an extent that the committee was scarcely able to provide sufficient accommodation. David C. Fenner, president of the club, officiated as toastmaster, introducing the following speakers: F. F. Beall, of the Packard Motor Car Company, who spoke on Production as one who knows his subject; E. W. Curtis, Jr., of the General Vehicle Company, who read P. D. Wagoner's paper on Advertising and Selling, Mr. Wagoner being absent on account of illness; Elisha Flagg, Jr., was also absent but sent his paper, which was ably read by the club's secretary, E. L. Howland; George H. Duck, general service manager of the Alco, gave a very interesting talk on service, enlivened by bits of humor; Walter Wardrop, editor of *Power Wagon*, was the last speaker and treated his subject, Past, Present, Future, in a very interesting manner. The occasion was a great success and augurs well for the continuance of the function as an annual affair.

Packard Contributes $150,000 to Road

The Packard Motor Car Company, of Detroit, Mich., has agreed to contribute $150,000 for the construction of the transcontinental stone road. This sum represents a little less than 1 per cent. of the company's gross business done June, 1912.

It has not been decided yet whether this sum will be paid all at once or in three annual installments, but the contribution is subject to the following three conditions:

1. It is to be paid only in case of sufficient funds being subscribed for the construction of the entire road scheme.
2. The engineering of the work must be supervized by government engineers.
3. The states through which the road is to be laid contribute the labor.

The latter condition is merely for the purpose of insuring the proper use of the fund contributed.

Willys Gives $150,000 for Stone Road

John North Willys, president of the Overland company, has donated the sum of $150,000 to the fund which is being raised for the purpose of constructing a national highway from one coast to the other. This donation is to be paid in three instalments of $50,000 each, payable during 1913, 1914 and 1915.

Des Moines Dealers Elect Officers

DES MOINES, IA., Jan. 20—The Des Moines Auto Dealers' Association held its annual meeting this week and elected the following officers: President, W. E. Moyer; vice-president, Dean Schooler; secretary, C. G. Van Vliet; treasurer, C. L. Horring; directors, W. W. Sears, C. G. Van Vliet, R. J. Clemons and V. W. Reynolds. On account of the illness of President Moyer the office of vice-president was created and Mr. Schooler will take active charge of the preparations for the fourth annual show, which opens at the Coliseum March 3.

Form National Highway Branch

YUMA, ARIZ., Jan. 20—At a meeting of more than 100 delegates from Arizona and the extreme southern section of California held here on January 8 there was formed the San Diego-Arizona auxiliary of the Southern National Highway Association. The special purpose of this organization is to promote the construction of a highway bridge across the Colorado River at Yuma. The proposed structure will cost about $75,000, of which sum the new organization pledges itself to contribute $50,000.

Savannah Owners to Pay for Roads

SAVANNAH, GA., Jan. 20—There is a growing feeling, chiefly among non-automobilists, that those who own automobiles should be required to meet more of the road expenses. From current talk this feeling is going to take definite form and shape when the legislature meets again this summer.

One difficulty encountered is the proper apportionment of the receipts from such a tax. Shall it go to the state or to the counties? Or shall part of it go to the state and part to the counties? These are questions which, of course, the legislature will have to decide. The people appear quite determined, however, that since the automobilists are the chief users of the roads, they should pay more toward their upkeep and improvement.

Secretary of State, Philip Cook, in the course of his investigations has discovered in one county where there are 177 automobiles registered that only nine of them have been returned for ad valorem taxation. He has found similar situations in other counties. This matter also will be brought to the attention of the legislators.

Electric Vehicle Association Banquet Is Success

One of the most successful affairs in the history of the Electric Vehicle Association of America was the testimonial banquet tendered to Past-President William H. Blood, Jr., at Delmonico's on the evening of Thursday, January 16. There was not a dull moment from oysters to demi-tasse and after that any one present would have thought that such a thing as "dull care" never existed. It was perhaps the most representative gathering of electric vehicle and central station men that ever assembled in New York City for a jollification in honor of one of their number. Arthur Williams, who is Mr. Blood's successor as president of the Electric Vehicle Association of America, acted as toastmaster of the evening and in proposing a toast to the guest of honor referred to his splendid efforts in behalf of the Association. Mr. Blood made a brief response in way of appreciation and among other things mentioned that the Association now represents approximately $500,000,000 of capital.

Newark's Automobile Show Plans

Next Thursday night the drawings for space allotments will be made for the Newark Automobile Show, Newark, N. J., which is to be held in the First Regiment Armory during the week of February 15-22.

Governors Represented at Convention

Twenty-nine governors have named delegates to represent their states in the second Federal Aid Good Roads Convention called by the American Automobile Association to take place in Washington, D. C., March 6.

Rhode Islanders to Hold Banquet

The Rhode Island Automobile Dealers' Association, Providence, R. I., will hold its annual banquet on Wednesday, January 29, at the Crown Hotel.

Chevrolet's Kerosene Experiment

A dispatch from Flint, Mich., states that the Chevrolet car, made by the Republic Motor Car Company, that city, will be mounted with a motor designed to use kerosene exclusively, and that the car is nearly ready for the market.

Hillman Speaks on Electric Trucks

At the meeting of the Electric Vehicle Association of America on Tuesday, W. H. Hillman, of the General Vehicle Company, read a paper on the importance of the electric truck as compared with other classes of central station work. Mr. Hillman showed the importance of the truck industry to central stations, due to current consuming ability of individual trucks and the rapidly growing number of electric freight automobiles.

London Taxicab Strike

Owing to Current Price of Gasoline 5,000 Taxicabs Have Been Removed From City Streets

Up to End of December Men Were Charged 16 Cents Per Gallon—Now Fuel Costs 25 Cents

LONDON, ENG., Jan. 13—Owing to the price of gasoline, 5,000 taxicabs have been removed from the streets. The trouble between the masters and men is that terms cannot be arranged over the price at which the drivers are to receive fuel for their cabs. Up to the end of December the men were charged 16 cents per gallon for all fuel required, but owing to the general rise, the proprietors, in accordance with the award that was drawn up last March between the masters and men with the Board of Trade, now have raised the price to 25 cents per gallon. The men refuse to pay this amount, and state that they would not be able to exist on this basis. They state that the average earning for a taxicab in London is $5 per day and out of this the proprietor takes $4.26 under the old charge of 16 cents per gallon for the gasoline, but under the new increased price he would take $4.50. Three gallons of fuel is required each day.

During the past year they state that the proprietors profit amounted to $140,000 less cost of handling, and with the increased charge this would bring them in a further profit of $65,000 for 1913. Against this the proprietors state that, and have actually taken the figures from the book of one of their employees, the amount of tips received is much better.

There are a large number of drivers who have remained loyal to their agreement of last March.

With the exception of the rush of Saturday evening for the theaters and other places of amusement, the average user of the taxi has felt little effect of the strike.

Benzol Tests Running in England

LONDON, ENG.—One of the London papers is running a series of tests on benzol. The owner and driver of a taxicab with which the test is being made drove 40 miles on this fuel under working conditions on the second day of the test, the car being fitted with a new Claudel-Hobson carbureter. He states: "I was able to approximate 22 miles on a gallon of benzol today, against 19 miles, my maximum, on gasoline. This was 1 mile better than my record of 21 miles on benzol on the first day, and the car was quite as efficient in every respect as on petrol, although I did not adjust the carbureter in any way for the new fuel. When I get used to the new carbureter I believe I shall do fully 24 miles per gallon on benzol under fair running conditions."

$12,500,000 Devoted to English Roads

LONDON, ENG.—Much useful work has been done for motorists in England by way of improving the roads over which they travel. During the last quarter of the old year the road board, with the approval of the treasury, advanced $413,610, the larger portion of which is to be devoted to road crust improvements. The total grants, after deducting cancellations, for the year amount to no less than $4,447,960, while loan advances to the extent of $633,160 have also been arranged. In addition to these vast sums of money, further advances amounting in the aggregate to $7,337,520 have also been dedicated to highway authorities toward road improvements, the details of which are not yet settled. The total, therefore, available for road improvements, amounts to the fine sum of $12,560,000.

Engineers in Session

HOWARD MARMON

Howard Marmon, elected president of the Society of Automobile Engineers at their annual meeting in New York City last week, is vice-president of the Nordyke & Marmon Company, Indianapolis, Ind. Mr. Marmon has been responsible for the design of all the Marmon cars since the advent of the company into the automobile field. He is a graduate of Leland Stanford University, and has been a leading factor in engineering and contest circles in America since his association with the industry.

Motor Testing, Exhaust Gas Analysis, Electric Wiring, Wheels and Fuels Are Discussed

Engineers Argue Relative Merits of Four and Six-Cylinder Motors—Discuss Best Gearbox Locations and Listen To Numerous Papers on Motor Design

THE annual winter meeting of the Society of Automobile Engineers held at the McAlpin Hotel, this city, was brought to a close on Saturday morning, January 18. The session was notable for the great amount of interesting and useful information which was brought to light and for the large number of prominent engineers who were in attendance and who entered into the discussions.

The Society has grown; it is now looked upon as the ultimate authority upon which engineers as a whole may rely. Realizing its great importance and increasing influence in its special line of work, automobile engineers are beginning to believe in it and are bringing to it their ideas and knowledge gained, in many cases by long years of experience along certain specialized lines. This assisting the less experienced, this spirit of co-operation is doing a great work for the industry as a whole. The idea of boosting was specially noticeable at the session just closed.

The Society's deliberations were opened on Wednesday, January 15, with the meeting of the Standards Committee at the headquarters of the organization. Here a number of division reports were considered and passed to the Society, where they were acted upon later in the week.

President Opens Session

The convention proper was opened on Thursday morning at the McAlpin by an address by President H. W. Alden. In summing up the work of the society since the summer meeting, it was pointed out that the policy has been to follow out the ideas of the late President Donaldson. The work of the standards committee was especially commended as representing the best efforts of the organization as carried on by the most able men which the industry possesses.

Mr. Alden spoke particularly of the work of the local branches, commending it as being the means of keeping up interest in the activities between the two annual meetings. Many would lose interest if they did not get together, if they were not afforded an opportunity to discuss pertinent topics more than once or twice a year. Local sections should be established in all the large cities, Mr. Alden said

He also touched upon a movement which is on foot for the endowment of the Society and which would be large enough to carry it over periods of depression so that it would not have to depend entirely upon dues and initiation fees for its upkeep.

Financially the Society is in better shape than ever before and the outlook is rosy, due to the rapid growth of membership and prestige of the organization. The total cash on band and in bank at the close of the year 1912 was shown by the treasurer's report to be $11,573.10 as against $2,230.04 at the end of the previous year. Total disbursements for 1912 were $28,379.32, while for 1911 about $22,000 was expended. This increase in expenditure is justified by the increase in membership and activities. The total receipts for the last three months were $17,293.58 and the disbursements for the same period amounted to $5,720.48. This sound financial condition is all the more noteworthy when it is considered that the only indebtedness of the Society is $4,000 in notes held by prominent members of the organization. This, of course, excludes the current running expenses.

Membership Grows Rapidly

The curve of increase in membership is practically a straight line and is still going straight up. The report of the tellers of election of members shows that 501 were taken in during the year, composed of various classes as follows:

Regular members	190
Associate members	233
Junior members	62
Affiliate members (11 persons designated)	5

Officers elected for the ensuing year were as follows: President, Howard Marmon; vice-president, J. G. Perrin; vice-president, Russell Huff; treasurer, Hermann F. Cuntz; members of the council, H. L. Pope, E. F. Russell and J. A. Anglada.

In tribute to the memory of the late Henry F. Donaldson, president of the Society at the time of his death, the Society appropriated from $300 to $500 for the erection of a suitable monument over the grave of the former head of the organization. The matter was brought before the Society by H. M. Swetland after it had been considered by the council and had met with that body's full approval. Mr. Swetland stated that it was desirable to have the concentrated action of tbe Society on such an action. Mr. Donaldson was a great man and a great writer, and it is only fitting that this tribute should be paid to his memory. The Society was unanimously in favor of the suggestion.

Society's Annual Dinner

Yet the convention activities were not all sterner business, for on Friday evening a record gathering of Society members was present at the annual banquet given in the banquet hall and the grill room of the McAlpin. Five hundred and seventeen members and their invited guests assembled at 8 o'clock for the Society's reception, after which the banquet was served.

No lengthy speeches marked the entertainment following the spread. The new president, Howard Marmon, outlined briefly the policy of the Society for the coming year, saying that he proposed to make all work. Following his opening remarks, Prof. F. R. Hutton, the only speaker of the evening, gave a short address, from which the following is an extract:

The Society's True Ideals

"The activity of your society largely depends on the work of the section, and the philosophy of this sectional work is not so much along the line of deep thought as to be up-to-the-minute information. Your sectional meetings call for knowledge of up-to-date requirements. The second great work of your society is the ideal of developing the standard. It is the development of this that relieves you from the influence of the sales manager and the advertising manager.

"Growth of membership should be the third ideal of your society, and I am pleased to note that your growth is as great if not greater than that of any of the other American engineering societies.

"The fourth ideal is that the engineer can expend less time in specialty work and more in broad views. He should be released from the petty details and be free for better and larger work in the development of materials and properties in the heat engine, along which line the art needs its greatest development. Scientific research is needed, and what our engineers require is that exact knowledge which comes from such research. My hope and dream is that our society will have a testing laboratory established in Detroit or some other city, and that it will be conducted along broad lines."

Summing up the professional work of this winter meeting, it is found that the discussions on the various pertinent subjects were particularly fruitful of valuable knowledge. Eleven committees reported and in every case progress was a feature. It was shown that the newly organized motor testing division will soon rank among the star dvisions of the standards committee. One evening was devoted entirely to four papers and discussions of motor truck subjects. An afternoon was given over almost wholly to a consideration of the value to the automobile engineer of exhaust gas analyses and related subjects. Four papers and discussion of them occupied another afternoon. These dealt with the subjects of leaf springs, the stability of propeller shafts, the effect of the relation of bore and stroke in automobile engines and the determination of brake capacity.

The broaches division report was accepted as one of progress. Consideration of new methods of spline manufacture and consequent changes of spline shaft design featured it. The ball and roller bearings and the frame sections divisions did not report. The miscellaneous division's report covered the standardization of another type of plain rod end. It also combined the specifications for height, width and length of magneto space on motors so as to apply to both four and six-cylinder engines.

The electric lighting committee provided that lamps should be 7-volt types with efficiency of 1.1 watts per candle. It also stand-

H. W. Alden, retiring president of the Society of Automobile Engineers, occupied the presidency since the death of President Donaldson, last July, and since that time has worked to carry out the plans of the late President Donaldson. Mr. Alden is chief engineer of the Timken-Detroit Axle Company

Representative gathering of members who attended the meeting held on the morning of January 17

ardized side, tail and headlights as to size. It is endeavoring to standardize storage batteries, to arrive at definite recommendations for wiring as to whether the single or the double system is preferable. It also seeks to standardize fuses and fuse boxes.

The sheet-metals division has given a specification for manganese bronze for cold rolled sheets and rods. It also is trying to reduce the number of sizes of sheets and rods used. The nomenclature division has laid out a long and difficult task for itself. It will attempt to get up a mechanical dictionary for publication in all languages so that each part will be rationally and uniformly known throughout the world. Other mechanical organizations and the United States Patent Office will undoubtedly assist at this work.

A committee has been appointed to arrive at standards for rims on account of the expected breaking up of the rim association, which will precipitate many makes of rims upon the market to the bewilderment of the engineer and the buying public. The alloys division added two specifications for gear bronzes. The wheel dimensions and fastenings for tires division will co-operate with the tire makers to decide whether or not they must revise the present stringent requirements as to rim tolerance, which now necessitate the rims being machined. The truck standards division reported progress along the line of standardization of the main related parts of the truck with respect to one another. The springs division also indicated progress. It is to endeavor to get additional information as to the distances fore and aft between spring clips for overslung and underslung springs.

Light was thrown on the consideration as to whether or not the magneto should be eliminated because of combined cranking, lighting and ignition; on the causes for the decline of the 42-inch wheel; on the subject, Will the Six Displace the Four-Cylinder Motor; on the best position for the gear box.

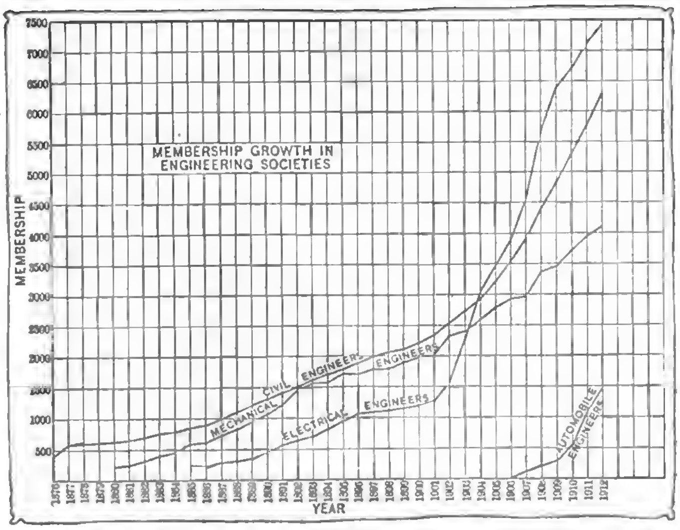


Chart illustrating growth of engineering societies, showing normal development of S. A. E. membership

Division Reports

Standards Committee Divisions and Electric Lighting Committee Reports Read and Acted Upon

S. A. E. Convention

IN addition to a business session on the opening morning of the Society's meeting, reports of several divisions of the standards committee and of the electric lighting committee were read and acted upon.

Report of the Sheet Metals Division

In addition to recommending a specification for manganese bronze for sheets and rods, the sheet metals division presented a report of its activities along the line of standardization of sizes of sheets and rods as used in motor car construction. The report was read by Division Chairman T. V. Buckwalter. According to it, the division's work divides itself into two parts. First, the presentation of specifications for sheet metals and rods, and, second, the submission of specifications for the dimensions of these materials. In order to arrive at what sizes for these to recommend, it is first necessary for the committee to know the preferred sizes as now employed by the manufacturers. Nearly every maker has his own special sizes, and at present there is no uniformity whatever.

For the purpose of ascertaining these particulars data sheets have been circulated to every maker asking that he note thereon his preferences as to sheets and rods. It is hoped that the returns on these requested data will be complete enough so that a number of definite recommendations may be submitted at next summer's meeting.

The composition of the manganese bronze as submitted follows:

Copper	.....56 to 60 per cent.	Lead impurities— not to exceed.....	0.25 per cent.
Tin	.... 0.50 to 1.50 per cent.	Zinc	Remainder
Iron	.... 0.50 to 1.50 per cent.		
Manganese	.. 0 to 0.75 per cent.		

This applies to manganese bronze in cold rolled sheets and rods and not to cast alloy. Manganese bronze is one of the strongest of the non-ferrous alloys, having a tensile strength of from 70,000 to 72,000 pounds per square inch. In thus submitting a specification for this alloy, the report states that the committee endeavored to tie it down to chemical combination only, rather than to include both chemical and physical considerations.

The report was accepted by the society as one of progress.

Report of Broaches Division

The third report of the broaches division was read by its chairman, C. W. Spicer. The report was short and was characterized as essentially one of progress. There was no discussion, no points being brought out which had not been touched upon in the general meeting of the standards committee on the day previous. There was no new data presented for consideration. The manufacture of broaches and splined shafts is still in its development stage and there is an increasing tendency toward the hobbing of splined shafts. The depth to which straight parallel sides can be cut by this hobbing method for six splined shafts seems limited and this may necessitate the changing of the tables relating to this work which have already been accepted by the society. It may be necessary to modify the form of the splines or to supersede the present tables by some dealing with a greater number of splines of a shallower cut. The depth is some function of the number of splines and the diameter of the shaft. The time during which the committee has been considering this point has been too limited to arrive at any definite conclusions as yet. The dimensions which have been adopted for squares and tapers seem to be meeting with approval by the manufacturers, Mr. Spicer said. The report was accepted as one of progress.

Nomenclature Division

The nomenclature division, of which E. J. Stoddard is chairman, has been in operation only a short time and hence has had very little opportunity to do other than make tentative plans for its line of procedure. Mr. Stoddard merely gave his views as to what was contemplated in an informal way, he having no specific report to submit at this time. The field of such a committee is great, he said, and there is much to be done. In each factory there are many words which grow up from the shops and which are not correct when applied to any particular part of the car. They are not generally received and are perhaps not understood by those in other shops.

Mr. Stoddard suggested a dictionary of terms used in the automobile business to be printed in several languages for distribution and adoption in all countries, so that the present confusion would be alleviated. For instance, there is a difference of opinion as to the correct term to apply to the transmission gears. Should they be known as the gearset or the transmission?

In fixing terms for the various components of the motor car, Mr. Stoddard pointed out that the words used should be of general application and not one which is merely satisfactory to any one small body of men or to any particular art. That is, when naming parts the society should not only be governed by its own members for the correct term, but should fix a word which is satisfactory as well to any other body of engineers when used by them.

Mr. Stoddard asked for the support of the society at large and hoped that he could be of service.

In discussing Mr. Stoddard's remarks, Howard Coffin pointed out the great advantage to the service departments if the public called parts by their proper names in ordering, so that their wants could be filled promptly and so that it would eliminate the present necessity in many cases of further correspondence to determine just what part the customer referred to. This would be a saving both to owner and manufacturer. The United States Patent Office has also asked for the assistance of the society in arriving at correct and definite names for parts of the automobile, many of which at present are referred to by several different words. Mr. Coffin suggested an illustrated dictionary, published in six languages.

No official action was taken on the report.

Miscellaneous Division

Chairman A. L. Riker's report of the proceedings of the Miscellaneous Division featured the modification of the table of magneto dimensions accepted at the 1912 annual meeting of the society so as to read as follows:

Four and Six Cylinder Magnetos

	MM	Inches
Shaft height	45	1.771
Distance from center 2 front hase-plate holes to large end of shaft taper	53	2.086
Distance from center front hase-plate holes to rear hase-plate holes	50	1.968
Distance from centers of hase-plate holes left to right	50	1.968
Large diameter	15	.590
Small diameter	12	.472
Length of taper	15	.590
Taper 1:5 (included angle) 11° 30′ approx.		
Woodruff key No. 3.		
Height of magneto space	203	8.000
Length of magneto space	254	10.000
Width of magneto space	127	5.000
Plain hole timing lever	6.35	.25
Tapped hole timing lever ¼ inch, 28 P. S.A.E.		
Base-plate holes, ⅜ inch 16 P. U.S.F.		
Thread for end of magneto shaft ⅜ inch, 16 pitch, U.S.F., length of thread .5905.		
Advance lever radius 2.125 inches.		

The first nine items of this table remain unchanged from the former table, while those referring to the heights, widths and lengths of magneto spaces have been combined so that there is only one size of space regardless of whether the design is for the accommodation of a four- or a six-cylinder magneto. The specification for base plate holes has been changed to 3-8 inch, 16 p., U.S.F. as here noted. The only added points are for the thread for the end of the magneto shaft and for the advance lever radius.

In the report the S.A.E. standard yoke and rod ends were taken up and it was recommended that certain plain yoke ends be added to the list standardized. That is, ends which are plain as differentiated from ball and socket types. It was further

Informal committee which discussed relative merits of single and double wiring systems for electric lights recommended that the specifications for the tensile strength and elastic limit of the standard screw thread material as previously fixed upon be stricken from the standards for the reason that the society should not dictate as to the quality of materials used but rather should confine its specifications as to dimensions.

In the short discussion of the paper which followed, Howard Marmon explained that the new recommended standard end is similar to the present adjustable end which has an extremely long clevice, except that it has a shorter end for use where such a long clevice is not required for adjustment.

The question of the practicability of the S.A.E. standard screw threads was brought up for discussion by the president. There seems to be some difficulty in using these standards for small sizes, some makers having to go back to the U. S. standards in these sizes. J. O. Heinze stated that in the plant with which he is coinnected the U. S. standards are used in cast iron and aluminum work while the S.A.E. threads are used for nut ends and the like. Mr. Marmon expressed substantially the same opinion on this point. It developed that in its fixing of these thread standards the division has already recognized that the S.A.E. threads are impractical for cast iron and aluminum.

Mr. Riker, in speaking of the striking out of the physical specifications for elastic limit and tensile strength, stated that there has been considerable feeling among the manufacturers of screws that this should be omitted for the reason that these working to the S.A.E. standards in other respects did not want to pay the additional price made necessary by this demand for such high-class material. It is the opinion of these screw makers that the physical properties of the material should be left to each engineer. The miscellaneous division's report was accepted as read.

Electric Lighting Committee

Alexander Churchward, chairman of the committee on electric lighting and its allied features, read a report which primarily recommended a very open discussion in the meeting of the subject of single and double wiring systems so that the views of the engineers could be incorporated in the later recommendations of the committee. These two systems differ in that the single wire system makes use of a ground for the return circuit, while the two-wire type uses a metallic return.

It was recommended that electric light bulbs be standardized and known as 7-volt lamps. These are to have an efficiency of 1.1 watts per candle at voltages ranging at from 6.5 to 7 volts. The size for headlights was standardized for the 2 1-16 inch size and capable of being focused in a reflector of 7 1-8 inches focal length or greater. Diameter of side and rear lights are fixed at 1 inch. Battery makers are to be circularized with the view of arriving at two standard overall heights and widths of storage batteries for automobiles so as to give three standard plate sizes from which batteries of any capacity can be made by simply increasing the overall battery length. Lighting system manufacturers are also to be circularized to fix standards for fuses and dimensions for boxes. The report also touched upon the consideration of dimmers for headlights as suggested by legislation now in force or under consideration.

The discussion on the subject of two-wire versus single wire installations indicated that the manufacturers or motor cars and also the makers of electrical apparatus will welcome the system of single wiring if it can be conclusively shown that its use is advantageous and not attendant with power loss and difficulty of maintaining proper grounds.

A. L. Riker stated that the electric lighting of automobiles is today in the same position as that occupied by the electric lighting industry in general 25 years ago. We should be able to adopt something as standard which will live and to profit by the experiences of the older and allied lighting industry. The single wire system eliminates many of the present troubles, he said. Its difficulties of good ground return are more theoretical than actual. In favoring the single wire system Riker further added that if it is possible to eliminate some of the elements and fixtures now called for with the present double wire systems, the modern automobile would look less like an electrical supply store and more like a real machine. The matter should be given deep consideration and not discarded without fair trial.

A. L. McMurtry stated that he has come to the conclusion that the single wire arrangement is undoubtedly the simpler especially in locating trouble. There is only one wire from the switch and only one to each of the lamps. In case of a short circuit there is only one wire to disconnect, while with the two-wire system there are two to be considered unless it so happens that the right one is struck the first time. With a first-class grounded system, there is less loss than in the poorly wired two-wire system grounded directly to the frame, said McMurtry.

R. H. Manson gave it as his opinion that any changing in systems should be done immediately rather than in the future, looking at the matter from the standpoint of the manufacturer. The single wire system requires a bulb with a different base than that of the two-wire system lamp, so that the present lamp with which snpply stores everywhere are stocked would be of no use, and it would take some time to affect the change in the dealers' stocks. In advocating the single wire system, he cited the telephone circuit as an instance of a grounded system working satisfactorily even though complicated.

Howard Coffin stated that he saw no reason for the retention of the present wiring if the other will work equally as well. Mr. McMurtry stated that half the troubles with lamps today is due to the delicate connections made necessary with bulbs for the two-wire outfits. This becomes especially frail in the smaller sizes of lamps. The single wire system would make use of very much simpler bases and sockets—the constructions would be much more substantial. Mr. Churchward brought out another point when he said that in the case of grounds, the single wire system is bound to blow out something immediately the ground defect is made, while with the present system in the case of a ground, there is only a slight leak which is not immediately noticeable and which will gradually sulphate a battery and thus drain it almost unnoticeably.

J. O. Heinze was practically the only engineer who was somewhat opposed to the new system, stating that in the great office building for instance we would not think of using one side of the building for a ground return. The two-wire arrangement he said gives twice the reliability.

E. T. Birdsall cited the example of the steel battleships which ground all their electric lighting circuits on the steel hulls. Mr. Manson advanced the counter argument that in the steel building there are so many different kinds of circuits that insulating them is necessary. Such installations are not analagous to the much simpler car wiring systems, he said.

In closing the discussion, Mr. Churchward stated also that the steel building illustration does not apply to automobile electric practice. All circuits in such cases are fed from the same mains, while in the car there are separate circuits for each unit.

The report was finally adopted as read.

Rim Standardization Action

Action was taken regarding the present situation caused by the internal dissension within the rim association. This matter was discussed in connection with the meeting of the standards committee as reported last week. There is a likelihood that the rim association will soon be disrupted with the result that the market will be flooded with many types of demountable and detachable rims. There are at present about five types of demountables and as many detachables. With this situation in view it is now high time for the society to step in and seek to standardize this part of the industry so that there will be one standard type of each class of rim—including the straight-side type.

Accordingly, the following resolutions were adopted by the society at the meeting of January 17:

RESOLVED, That, there are too many pneumatic tire rims in the market;

That this society believes that a much smaller number of rims will satisfy the needs of the industry and at the same time will bring about a great saving;

That the committee appointed to consider and report upon this subject shall proceed at once to hold such meetings and hearings as will bring about an improvement in this situation;

That a report be submitted at the earliest possible moment;

That this committee shall co-operate with the National Association of Automobile Manufacturers and with the Automobile Board of Trade.

The committee to consider an improvement in the rim situation for pneumatic tires was appointed and has as members representatives from the several industries involved. The membership of the committee is as follows:

H. L. Barton of the General Motors Company, Detroit, Mich.
G. G. Behn of the Hudson Motor Car Company, Detroit, Mich.
C. E. Reddig of the Timken Detroit Axle Company, Detroit, Mich.
C. D. Williams of the Mott Wheel Works, Utica, New York.
J. J. Vincent, Packard Motor Car Company, Detroit, Mich.
C. B. Whittelsey of the United States Rubber Company, Hartford, Conn.
H. E. State of the Goodyear Rubber Company, Akron, Ohio.
Henry Souther, Consulting Engineer Standard Roller Bearing Company, Philadelphia, Pa.

A meeting of the committee was held and it was decided to hold a meeting in Cleveland, O., at the earliest possible moment.

At that meeting the final organization of the committee will be accomplished. Following this meeting a hearing will be given to all those interested in the situation, that is, to those having rims which they would like to have adopted as recommended by the society.

Those appearing at the hearing will be requested to produce the metal parts of a rim complete as furnished, including felloe band and all attachments.

The weight of these parts will be carefully scrutinized and will form an important consideration in the choice of any rim. No specially prepared or machined exhibits will be considered. The rims and parts must be exactly as furnished commercially.

A complete wheel with tire must also be furnished for demonstration purpose.

The standard size of all exhibits will be 36 by 4.5 inches.

Tools for attaching and detaching and means for inflation must also accompany the exhibit.

From the Maker's Standpoint

E. R. Hall discussed the situation from the standpoint of the tire manufacturer, stating that all such concerns would welcome a standard rim of low cost and easy operation which would not work a hardship upon the manufacturers as far as cost was concerned. H. B. Bannister, a wheel manufacturer, stated that both the wire and the wood wheel makers would welcome the society efforts along this line. S. W. Alden pointed out that the committee would give a full hearing to all concerned since it is made up of men whose activities cover every branch of the trade. F. A. Bower gave it as his opinion that the action was a most excellent thing on account of the greater economy which it would work for all manufacturers. H. L. Pope said that the move is the proper one. There should be a single rim and the committee is capable of adopting one. This may not be the best possible, but it will be the one which the committee finds to be best adapted to all classes of work as far as it can determine at this time. In any case the right one will be settled upon eventually as a result of the committee's deliberations.

Mr. Souther took up the intended action at the Cleveland meeting in details and stated that no favorites will be played. The object is to arrive at a standard type which will work for the greatest good of the greatest number. Any arrangement which this committee makes will include compettition, he said. The action of the committee was approved by the society.

J. C. Heinze, in his report on motor testing methods, outlined by charts the various testing apparatus used by him at the Northway motor plant, and as chairman of the committee recommended that the society should collect data on how motor testing is done at the different factories. The first sheet exhibited was that of a standard form for recording results of motor tests. It should, according to Mr. Heinze, contain the following information: 1—Name of company; 2—Name of report; 3—What test consists of; 4—Date; 5—Where report is recorded in the office bulletin; 6—Such facts as specific gravity of gasoline, temperature of gasoline, temperature of room, temperature of water, barometric reading, and relative humidity; 7—Model number of motor, and motor features; 8—Kind of dynamometer used; 9—Name of carbureter and type, name of magneto and type, name of spark-plugs and type; 10—Weight of motor, weight of pistons and connecting rods, amount of cylinder offset from center line of crankshaft; 11—Name of engineer making test; name of assistant engineer; 12—Space for standard curve on regulation section paper (the vertical should indicate horsepower from 1 to 100, and the horizontal crankshaft revolutions from 2,000 to 3,000, and piston speeds in feet per minute; this should also show the horsepower output per cubic inch of piston displacement, and if a 63-inch beam, or shorter was used); 13—This particular chart shows six curves: A—Curve of motor; B—Torque curve at different speeds; C—Air consumption in cubic feet per minute, without carbureter; D—Air consumption in cubic feet per minute with carbureter; E—Gasoline consumption in pounds per hour, and F—Gasoline consumption in pounds per minute per horsepower, or per horsepower-hour.

Plotting the Air Curve

It is necessary to plot the motor's air curve when a carbureter is not attached in order to get accurate volumetric efficiency. By doing this you can also show the losses due to the carbureter, which often amount to 10 per cent., and which fact is an important one for consideration when selecting the different carbureters to be used.

Accurate record of gasoline consumption is taken in order that the efficiency of different carbureters can be gauged, and it is impossible to get this without plotting the air curve. Taking the air curve also enables one to obtain the mechanical losses in the engine, due to connecting rods, pistons, etc. By plotting the mechanical losses in the same motor, with off-set cylinders, and then with the cylinder centers in line with the center of the crankshaft, you are enabled to obtain the best percentage of offset.

The air consumption curve also aids in the design of the camshaft as it shows one when one has the maximum volumetric efficiency. To readily determine this a long sliding cam is used which is practically V-shaped at one end, and nearly rectangular at the other, and with every gradation between these extremes intermediate of the ends. By sliding this cam it is possible to get the design that will give the maximum volumetric efficiency. The type of cam selected depends upon what the manufacturer desires by way of a motor. If the design is for a touring car, one type of cam will be used, but if for a racing machine another type can be used.

The various testing apparatus used by Mr. Heinze, and reproduced on charts, will be published in a later issue of The Automobile. They consist of an air meter placed in series with the carbureter; water tank arrangements for measuring heat losses through the jackets; radiator testing apparatus; apparatus to show period of ignition instead of depending upon magneto breaker box; device for measuring the temperature of the spark; apparatus for measuring carbureter acceleration; apparatus for measuring motor vibration between different ranges of speeds; electrical device for measuring waves in primary and secondary transformers; and other apparatus for measuring cylinder compression.

Christian Girl in presenting the report of the spring division which was to have been submitted at the June session, stated that the work of his committee was rather to simplify the spring situation, so far as the manufacturer was concerned, than to standardize parts. The report was accepted as a progressed one. The committee has before it the collection of information on the best length of spring pads or seats for overslung and underslung springs, and also the accepted distances fore and aft between spring clips, for springs of different lengths.

T. V. Buckwalter in presenting the report on aluminum and copper alloys recommended an alloy for general utility of:

Copper	87 to 89	per cent.
Tin	9.5 to 10.5	per cent.
Zinc	1.5 to 2.5	per cent.

In the United States standards the divisions are: Copper, 88 per cent.; tin, 10 per cent.; and zinc, 2 per cent. The recommended specifications give an alloy with reasonable working limitations, and with a tensile strength of 35,000 pounds.

The copper alloy recommended for gears, worms, etc., is:

Copper	88 to 89	per cent.
Tin	11 to 12	per cent.
Phosphorus	.15 to .30	per cent.

and can be manufactured by any good metallurgist. The report was accepted.

Exhaust Gas Analysis

Measurement of Air and Gasoline Makes It Possible to Determine Whether Proportion of Each Remains Constant

S. A. E. Convention

THE topic of exhaust gas analysis discussed during the Friday afternoon session was one of the best attended and most interesting of the week. A number of authorities on the subject were on hand to expound their ideas and experience which in several instances has extended over a long period of years. Dr. Arthur H. Elliott was scheduled to present a paper on the analysis of exhaust gases but owing to illness was both unable to prepare any material and also to be present to aid in the discussion.

The analysis of the exhaust gas of an automobile motor is becoming to be looked upon as necessary to the proper determination of the efficiency of the engine under test by many engineers of long experience in testing work. By means of data as to constituents of the waste gases the engineer is able to determine whether or not the motor is getting all of the useful energy and power out of the mixture.

In the absence of Dr. Elliott several notes on the subject were hastily prepared by Herbert Chase, laboratory engineer of the Automobile Club of America, who dealt with the subject in its relation to carbureter and engine testing. Mr. Chase said:

"Some of you will doubtless recall that I gave you in the paper which I read before the society at its last summer meeting some data which I had obtained along this line in testing a six-cylinder Pierce motor. Since that time I have conducted a considerable number of tests in which samples of the exhaust gas were taken and analyzed. I am now convinced that I was correct in the impression stated in this paper that a much more satisfactory method of taking the samples of exhaust gas could be employed than the one there outlined. We now use a method which gives much more consistent and satisfactory results for reasons which I will shortly point out.

"It has been our practice to make tests along very much the same lines as indicated by Mr. Heinze in his discussion of motor testing, although the methods which we employ differ somewhat in detail. In addition to measuring the air and the gasoline which enter the motor, we also analyzed samples of the exhaust gas for the following reasons:

"Measurement of the air and the gasoline makes it possible to determine whether or not the proportion of each remains constant. Aside from this, one very important factor remains to be determined, namely, Is the gasoline properly mixed with the air in such manner that each molecule of oxygen and hydrogen will come into contact with a molecule of oxygen during the very short period of time when effective combustion takes place? It may be argued that this question will be answered by measuring the horsepower at the same time that the air and gasoline are measured and concluding that a better diffusion of the gasoline in the air is obtained, when, as a result of some change in the method of spraying without changing the proportion of air to gas the power increases. This process can be followed with reasonable satisfaction up to a certain point, but when is the investigator to know whether or not still better results could be obtained until he has determined the completeness of combustion?

"There are other arguments in favor of analyzing the exhaust gases. One is the convenience and simplicity of the determination but means for measuring the air are not at hand. In road testing it is quite easy to make samples of exhaust gas for later analysis, whereas air measurements would be exceedingly difficult, if not impossible.

Prominent Engineers Discuss Exhaust Gas Analysis
Howard Coffin W. C. Marshall A. L. Riker

"Professor Watson, an English investigator of considerable prominence, has obtained the curves given herewith. These provide a means of determining what the approximate proportion of air to gas is when direct measurements of the quantity of both cannot be conveniently taken. They, of course, apply only when the combustion is complete, in so far as it can be complete with the quantity of oxygen present.

"With the price of fuel rapidly increasing it now becomes more important than ever to get the greatest possible amount of power out of the given amount of fuel. I am very decidedly of the opinion that this object could be obtained more readily if engineers would give more consideration to exhaust gas analysis.

"Chart two is also taken from one of Professor Watson's papers. It shows the per cent of fuel wasted with the given per cent of carbon monoxide in the exhaust. I may say also that Professor Watson has found in some of his investigations that the maximum power of a motor is obtained with a ratio of air to gas from 12 to 1 to 13 to 1 by weight. He has determined that the maximum thermal efficiency corresponds to about 17 parts of air to 1 of gasoline. Other investigators state that about 14 parts of air to 1 of gas, which is approximately the theoretical amount necessary for complete combustion, gives the best thermal efficiency."

The discussion of the subject was opened by E. R. Hewitt who has had wide and varied experience along this line. He outlined the apparatus which he uses in making exhaust gas analysis tests on the road and explained the method of attachment to the car. The necessity for rapid collection of the sample of gas to be tested was emphasized. It was also brought out that results obtained by road tests are not the same as those under brake test conditions. The reasons which Mr. Hewitt gave for this difference are that the jar of the motor on the road affects the carbureter float level and also the variation in temperature under the hood has a bearing on the results obtained. He stated that there was a difference of 15 per cent. to 100 degrees Fahrenheit variation in temperature. For greatest efficiency on the brake as well as on the road Mr. Hewitt has determined the following exhaust analysis:

13.5 per cent.......... CO_2
0.1 per cent.......... O
0.2 to 0.3 per cent.......... CO

Whenever an analysis of the exhaust gases does not check up as would be naturally expected, the deviation from the normal conditions may be ascribed to poor carburetion. The normal analysis would show intimate mixture and complete combustion.

Mr. Hewitt touched upon tendencies for condensation within the manifold. With any carbureter whatever with velocities in this carbureter below 5,000 feet per minute, it is impossible to get away from condensation within the manifold. We get best results at 15,000 feet per minute.

Mr. Hewitt has determined that the maximum efficiency mixture has approximately the following composition:

12.5 per cent.......... CO_2
2.0 per cent.......... O
0.0 per cent.......... O

Mr. Hewitt has made a number of tests with the view of determning the effect of the action in the intake both on the power developed and on the mixture and has found that 1 inch mercury suction defects the power about 10 per cent., which relation holds up to 3 inches of mercury, so that if it were possible to reduce the suction to zero, we would get an increase in power of about 30 per cent.

J. M. Breitenbach gave his opinion that another reason for power loss in motors designed according to American practice is that the explosion chambers are too large and that another is on account of incorrect timing.

Prof. W. C. Marshall, Sheffield Scientific School, Yale University, added some most interesting points to the information already given out, his ideas coming as a result of a number of road tests made under varying conditions of speed and with different types of motors, during the past summer. In his experience he has found that under road conditions the analysis compare very closely with those given by Mr. Hewitt. He pointed out that from the amount of CO_2 which is present in the waste gases is a very correct indication of the fuel consumption of the motor. For instance when from 5 to 6 per cent CO_2 is found, the car averages from 4 to 5 miles on a gallon of fuel, while when the exhaust shows 12 to 13 per cent. CO_2 the economy runs up to three or four times as much.

Looking at the practical side of the problem Professor Marshall stated that an exhaust gas analyses as applicable to automobile engineering are not so difficult as to cause any engineering department to hesitate to make them. Determination of the composition of the waste gases not only affords a means of gauging the economy of the motor but also makes it possible to arrive at the relative efficiency of the carbureter.

Mr. Hewitt in reply to a question as to what engines he used for his tests stated that he had employed two machines for the purpose, one a four- and the other a six-cylinder model. The cylinder dimensions of these two motors are the same, being 4 by 4.75 inches. He averages from 21 to 24 miles per gallon with the four-cylinder type and 14.5 to 15 miles per gallon with the six.

W. G. Wall, chief engineer of the National company stated that he has made a number of exhaust analysis tests during the last 2 years, and that due to the many variables such as the size of the intake, the shape of the ports and so on, he has come to the conclusion that gas analyses are of very little value. When very best theoretical results are obtained they are of little use from the practical side. He has been unable to arrive at any definite conclusions by this method of motor testing due to the many contradictory results.

Leaders in Exhaust Gas Analysis Discussion
Herbert Chase Edward R. Hewitt

E. J. Stoddard touched upon the chemical manipulation in connection to accurate analyses. Engineers are somewhat weak on this phase of the subject, he said. He inquired as to whether the absorption of oxygen is liable to produce CO in itself. The reply was negative.

Mr. Hewitt was requested to outline briefly his method of procedure in making exhaust analyses. The CO_2 is absorbed first after which the oxygen is removed which leaves only the CO. In discussing carbureters in this connection he stated that he has tested in all about thirty types, and that the analysis does not depend upon this feature. One carbureter will work well at one particular range of speed and may be very poor at a lower or higher range. There is no carbureter at present which works equally well at all speeds. In the average case the carbureter is adjusted for too rich a mixture at all times. This is due to the fact that it is impossible to compensate for differences in temperature under the bonnet so that if an instrument is adjusted for best running at a good speed, it is very poor for starting purposes. Dash carbureter adjustment for manually changing the mixture in accordance with these varying conditions is therefore necessary.

T. S. Kemble believes that horsepower and other block tests are equally as good for arriving at the efficiency of motors and for deductions as are an analysis of the exhaust.

In closing the discussion Mr. Chase mentioned the point of dissociation and recombination which has been brought up earlier as a possible theory as to the action of the gases in burning. He stated that the society would be authoritatively informed on this point later. The great amount of trouble which some have with analyses may be ascribed to the methods of collecting the samples. It is important to get these samples without admitting any outside air and also to attain them under average conditions.

Closely allied with the discussion on the analyses of the burnt gases in the automobile motor, was the paper presented by G. T. Briggs and prepared by C. P. Grimes on the subject of motor testing. The paper follows:

This paper presents in a general way points which have been observed through the aid of our testing laboratory to be most influential in attaining a perfected power unit. The nature of our work is such that we seldom have time to enter into a detailed analysis of any one motor, but by careful observance and record of the general performance of each motor that passes through our dynamometer test, we are able to give what we believe to be a comprehensive idea of the predominating features that produce results.

The general running balance of a motor, though generally conceded to be a matter of design and manufacture, has been found to be affected greatly by carburetion. A case in point was a long-stroke L-head motor of standard make equipped with a stock carbureter. At 22 miles per hour the motor would vibrate so violently as to shake the whole car. By changing to a different type of carbureter the point of vibration was eliminated almost entirely and could be detected but slightly at a speed of 32 miles per hour.

The requirements of ignition are in general very well known. We have found, however, that a material percentage of ignition trouble can be traced to a lack of symmetry in timing. Our special instrument for the purpose has often shown one of the sparks to pass out of synchronism with the others as much as 5

Snapshot of Gas Analysis Controversy

Engineers Discuss Dynamometer Testing
R. W. Funk A. L. McMurtry D. Beecroft G. T. Briggs

degree which would be quite noticeable under idling conditions and be indicated on a dynamometer test. Motors with a set spark will not show the best range of action in power or throttling. We have found it impossible to put as much snap or getaway into motors that are equipped with an automatic spark advance as into those with mechanical advance. Further, the rate of flame propagation in a gaseous mixture, other things being equal, is near its maximum at a 12-to-1 ration. The rate decreases with departure from this value in either direction, so that at any given speed there are a number of different best settings for the spark advance.

The number of cases brought to our attention have assured us that carburetion has far more to do with ignition than is generally recognized; depending upon how well the carbureter can be made to do its work of producing a homogeneous gas.

The question of manifolds is one of not alone great source of error, but is often a very delicate subject, especially in the case of a pet design. Experience gained from building a number of different designs leads me to say that in the final analysis the problem is purely and simply a matter of aerodynamics, not to be guessed at. The mixture traveling in the intake manifold may be likened to perfect dry steam or when filled with particles of liquid, wet steam. The designer of a manifold should bear in mind that steam separators are built with rough surfaces and sharp turns in order to accomplish separation. The function of the manifold is to distribute the mixture in exactly the same proportion as received from the carbureter without separation and with the minimum loss of head by friction.

Any device to improve the condition of the gas should be welcomed, such as a heat jacket or passing the gas through cored passages in the cylinder block casting. Before adding the best device the ultimate result on the power of the motor should be considered. If the jacket involves no increase in suction in the manifold, 2 per cent. in volumetric efficiency and power will be lost for each rise in temperature of 10 degrees, Fahrenheit, of the gas. If the heat device causes added suction in the manifold, about 4 per cent. in volumetric efficiency and power will be lost for each inch of mercury that the suction may have been increased. These statements may appeal to you as explaining increased power of a car on a cool evening and the decrease of power with ascent into a higher altitude.

If designers gave a little more consideration to the fact that the gases traveling in the manifold weigh about three times as much as air and move at the rate of from 300 to 400 feet per second with considerable momentum, I believe we would see far more consistent results, and that much of the uneven running due to oscillatory surges could be avoided.

The most effective manifold is not always the shortest that can be built. But of two things I feel positive, namely, that a long vertical lift of the carburetted gases is not only unnecessary but vicious practice that does rank injustice to both the motor and the carbureter. Furthermore, smooth streamline passages should always be adapted in manifold construction. The lack of these requisites has often been the means of discounting an otherwise well-designed motor.

As an aid to investigation I suggest that in the event of a newly designed motor running unevenly, the exhaust manifold be removed, giving each cylinder an equal chance to scavenge. The color of the flame from the ports may be taken as a criterion of the distribution from the inlet manifold. It is not uncommon to find that the injector action of the gases will tend to scavenge some cylinders and foul others.

Carburetion is a subject upon which very few have definite and reliable information. Before a new model carbureter is adopted, we test it in our dynamometer room to determine torque, horsepower, economy, volumetric efficiency and richness of mixture at every speed. By a specially designed instrument records of revolutions passed through, gasoline consumed and air consumed are made electrically, a split-second timepiece without any chance for human error to enter being used.

A thorough road test is then made, after which the whole car is placed in a refrigerating plant and the temperature reduced to 5 degrees, Fahrenheit, above zero, so that we may study the conditions of starting, running and power delivered at the wheels in winter.

We feel prompted to make the assertion that the American public will not accept a carbureter that gives a uniform mixture under all conditions, but demands a quick getaway, economical running and a powerful mixture at maximum speed.

I submit herewith some data taken from a test made in our laboratory on a four-cylinder block motor 3 3-16 inches by 5 inches, of the water-cooled poppet-valve type.

R.P.M.	Lbs. at 36"	H.P.	R.P.M.	Lbs. at 36"	H.P.
600	48.7	16.70	1400	49.6	39.75
800	53.0	24.22	1600	48.0	43.95
1000	54.7	31.25	1800	46.6	48.30
1200	52.5	35.95	2000	44.9	51.20

Exhaust valve diameter = 1.875". Inlet = 1.8125". Lift = 0.3125".

The valves, eight in number, were placed in a row on the top of the block casting.

The secret of the whole performance may be found, we believe, in the fact that the designer of this motor recognized the laws of aerodynamics and handled the gases accordingly.

Before closing, we wish to state that consumption of fuel is, to a very great extent, a personal equation, to be solved by each individual motorist. Our records show that the best economy per brake-horsepower-hour was obtained with a 14-to-1 air ratio and that with this setting no *CO* could be detected in the exhaust. We admit that this ratio would not please those who are always in a hurry to get started or delight in darting around slower vehicles, but for each percentage of *CO* permitted in the exhaust, from an overly rich or snappy mixture, a net loss in fuel of 4 per cent. will be suffered. I wish to add that the majority of cars delivered to owners by salesmen and testers emit as high as 10 per cent. of *CO*, which represents a waste of nearly 40 per cent. of the fuel fed to the motor.

Mr. Hewitt was again requested to open the discussion, bringing up the point of smooth versus rough inlet passages. His tests favor the rough cast metal type so that the fuel may be broken up by the surface with which it comes in contact. Although advocating rough passages, he pointed out that the corner should not be so sharp as to offer resistance to the flow of the gas. He was asked if the rough surface would not materially tend to cause condensation on the rough edges and replied that he has always jacketed these inner passages and hence has had no such trouble.

Mr. Chase held that proper ignition is important to get best results. In comparing two carbureters it is necessary to insure constant ignition which is equally as efficient when one carbureter is used as when the other is under test. It is unfair to make comparisons relatively when these conditions are not the same. Comprehensive tests should also take into consideration atmospheric conditions such as a barometer pressure, humidity and so on. Touching upon manifold construction, he advocated the use of the straight type with branches to the cylinders.

J. O. Heinze discussed the point of manifold construction and stated that if possible the intake pipe should vary in length in proportion to the speed of the engine. Inasmuch as this is impossible the length used should be the best possible medium between the very long and the very short, so as to efficiently take care of the greatest range of speed. To bear out this assertion he outlined a number of tests which he has made with glass tubes in which the action of the mixture in combining could be witnessed. In order to mix the air and gasoline a certain constant time is necessary, hence, the greater the engine speed the longer should be the passage for the gas so that it may have sufficient time for combination.

Prof. F. R. Hutton made an appeal for greater definiteness for the term carburetion in view of the present tendency toward the use of heavier fuels such as kerosene which when combined with air to make an explosive mixture cannot properly be classed as strictly carburetion. While the manifold has a very important function with gasoline, it is still more so with less volatile fuels, such as kerosene.

Speaking of Prof. Hutton's talk on the misuse of the word carburetion and his ideas of the applying of a term such as atomizer or vaporizer to the device which mixes kerosene with air, Howard Coffin was of the opinion that the engineers are interested more in the results obtained through the use of these newer mixing devices than they are in the nomenclature. Mr. Coffin spoke further of a number of tests which have been made at the Hudson factory which have led him to come to the conclusion that if it were possible to so construct the motor that at the end of the suction stroke after the cylinder had been filled with all the charge which would be taken through the carbureter, were possible to inject fresh air immediately over the top of the piston and in proper proportion the mixture would be entirely consumed. In these tests it was found that carbureter troubles were eliminated, the cylinder oil even being entirely burned so that there was no semblance of carbon. This burning with excess air if developed means the production of much greater power than now obtained from motors of given dimensions and would mean that bearings and other parts would have to be strengthened and redesigned for the greater forces exerted. It is now possible to get greater power out of a motor than present practice can take care of.

Mr. Hewitt stated his belief in this idea also although he pointed out that maximum practical compression pressures have been determined of from 72 to 78 pounds per square inch. In the average case 72 pounds per square inch is about the maximum which can be carried. Mr. Hewitt has found that ordinarily an engine will completely fill its explosion chambers with the combustible mixture up to 1,000 revolutions per minute but not above this speed.

F. S. Dusenberg stated that cam setting effects compression and that he has obtained in motors of his design as high compression at 1,500 as at 1,000 revolutions per minute.

Mr. Heinze outlined some experiments which he has made by heating of the intake passages. These experiments contemplated the winding of wire around the pipe and then passing a current through it thus obtaining a greater heat than could be obtained by hot water jacketing. He found no advantage of heating these manifold pipes although very beneficial results were obtained when the fuel in the bowl of the carbureter itself was heated. Large increase in power was thus obtained.

Road and Dynamometer Testing

At Friday afternoon's session a discussion of the relation of road testing to dynamometer testing brought forth some good points. According to E. R. Hewitt, both are essential. Herbert Chase advocated more accurate road tests than those now performed. Much can be gained from such determinations, he said. These tests should be standardized just as much as should those relating to the laboratory or block. It is exceedingly difficult at present to compare results of tests by different persons as apparatus used, methods, and data are widely at variance. An instrument is needed for accurately obtaining horsepower and torque readings on the road, said Chase. H. L. Pope suggested that the motor testing division of the Standards Committee have its scope broaden so as to include road tests in its standardization work.

Prof. W. C. Marshall said that road tests are neglected by many manufacturers. Just as valuable information and the same information may be obtained on road tests provided an accelerometer is carried. To prove this as certain Prof. Marshall showed torque curves could be plotted from readings taken from such an instrument. Torque curves thus obtained are more valuable than the laboratory kind, in that they are taken under real road conditions.

Although there were some who were not in favor with the road tests and could not see their advantage the majority of those present are awake to the advantages to such methods of obtaining data.

Ignition, Motors and Gearsets Discussed

S. A. E. Members Argue Pro and Con on Six-Cylinder Motors, Rear Axle Gearsets and Electric Starting Systems

WILL the magneto as at present fitted be discarded owing to the adoption in some quarters of the cranking motor, lighting plant and ignition being contained in one unit?

A. L. McMurtry opened the discussion on the subject by stating that the high-tension magneto as at present used was a most reliable instrument. When the question of a combined system of starting, lighting and ignition system was considered, the element of security was not so great as with the present magneto, as it only requires a short circuit anywhere in the various leads, to render the ignition system useless.

Question of Weight and Cost

A. L. Riker thought that it was a question to determine whether the same result could be obtained with the one unit as well as with the three unit? Further, if the result were the same, what the relation would be in point of view of first cost? He thought that a combined unit would cost less, but the relative weights and space occupied were also points that would have to be considered.

Mr. Hartford agreed with Mr. McMurtry that it was better to continue to use the high-tension in addition to the other electrical equipment employed for starting and lighting.

Professor Hutton said that he had had some experience with this situation and had experimented with two batteries, but owing to the lack of standardization in wiring he was continually troubled with short circuits. Until the methods of wiring are improved, he thought that the present plan was the better. A possible solution was the motor and generator combined and the outcome of experiments along this line might be satisfactory. In the speaker's mind there was a doubt, and the question resolved itself as to whether it was desirable to attack the effectiveness of the motor in any way?

V. G. Apple believed that for commercial reasons that it was better to continue to use the magneto for ignition purposes. He advocated taking the current from the battery for starting purposes only.

Mr. McMurtry pointed out that the Bosch company has brought out a small magneto to be fitted on the dash for starting purposes, thereby doing away with the battery. He thought that there must have been a reason for this and went on to state that it simplified the system considerably as the batteries had other duties to perform.

H. L. Pope stated that it was best to leave the magneto alone for the present. He thought that the time would soon come, however, when the various systems would be combined. There would be a saving of weight and less initial expense also.

Howard Marmon stated that it has taken a number of years to develop the magneto to its present reliable state, and one advantage of the magneto is that as the speed of the motor increases the intensity of the spark increases also. This fact simplified control.

Mr. Alden said that no doubt it would be the survival of the fittest in the long run.

"Why has the 42-inch wheel been discarded?

Mr. Alden said that it was not so much a question of the 42-inch wheel being discarded as that it had failed to grow in favor and he called upon the several members present to give their opinions upon the matter.

Mr. Riker pointed out that the majority of Americans wanted to carry three people on the rear seat and to do this it was necessary to have an overall width of 57 to 58 inches. The public also wanted to be as near the ground as possible. With a 42-inch wheel, 57-inch tread and a body width of 57 inches the tendency of the larger wheel design was to perch people high up in the air. Then there was the question of the additional cost of the tires and he did not think that the advantages gained by the large wheels were in proportion with the extra cost entailed. To hang the body low and use large wheels is not feasible without increasing the tread and he did not think that this was a move in the right direction.

Mr. McMurty said that he had built a horseless carriage in 1897 to which he fitted large wheels and experienced considerable trouble from broken axles and broken steering spindles. The size of the wheels was originally 40 inches and upon reducing the size of the wheel to 30 inches the axle trouble disappeared.

Professor Hutton pointed out that the increased diameter of the wheels gave a longer lever arm to the body and that heavier brakes would be necessary. It was a question in his mind whether the better riding qualities was imaginary or not.

Mr. Alden stated that he had ridden in several cars with large diameter wheels and with smaller ones under the same conditions and he had experienced more comfort with the large wheels.

War of Fours and Sixes

"Will the six-cylinder motor eventually displace the four-cylinder for passenger cars?"

Several members expressed the opinion that the four-cylinder would remain the logical motor for automobiles the purchasers of which had to study economy either from the point of view of low cost of purchase as well as low operating costs; but for those who were willing to pay the price, the six-cylinder would prevail. Mr. McMurtry stated that while in Europe he had ridden many miles in several of the small four-cylinder cars which are invariably fitted with four-speed gearsets and provided one did not want to continually drive on high gear the efficiency of these little machines left nothing to be desired.

Professor Carpenter said that 12 years ago prophecies were made that the single-cylinder would be the ultimate type, and in some years to come they might find that any of the prognostications made at this date might equally fall short of the mark as those made in the last century. He thought that the four-cylinder would always be in demand. It met the requirements for the light vehicle and in this field he did not think that it would ever be displaced.

Mr. Alden said that he had a town car with a very small motor and a final gear reduction of 4.25 to 1 and that it was entirely satisfactory. While it only had three speeds it was only used for town work, but in the case where the type of car was used for country driving it was fitted with four speeds.

Mr. Pope remarked that one item to be considered was the manufacturing cost and also the question of weight. Despite the fact that some of the builders of small cars were fitting six-cylinder motors at present he thought that they would come back to the four-cylinder type.

Mr. Heinze said hat it was common knowledge that the thermal efficiency of the four-cylinder engine was superior to that of the six. By fitting a heavier flywheel to the four it was possible to make it run as smoothly as six, although this reduced the accelerating properties. Owing to the more constant torque the six accelerates better than the four. If the purchaser did not consider economy undoubtedly the six-cylinder was preferable. The advantages of the four-cylinder are power with economy and a minimum of weight.

Mr. Kemble stated that for a matter of economy the four is undoubtedly the better, but for those who want luxury the six is preferable. He thought that there would always be a demand for both four and six-cylinder motors.

Mr. Riker said the four is more economical to build and also to run. The reason why six cylinders have in many cases supplanted the four is due to the lesser vibration of the six. He noticed that customers who have ridden in fours and sixes express a preference for the six and when asked the reason cannot explain. He gave the matter some thought and stated that the reason came to him while he was making some bench tests. While a four-cylinder motor is running at from 1200 to 1300 r.p.m., the stand carrying the motor being bolted to the factory floor, it is almost impossible to keep the heels on the ground due to the vibration set up, but in testing a six-cylinder motor at the same engine speed he did not notice any inconvenience. The sensation experienced after driving continually behind a four-cylinder car for 200 miles at a stretch is one of fatigue, while after driving the same number of miles behind a six-cylinder motor he did not feel at all tired. He was of opinion that the absence of vibration in the six-cylinder motor is a determining factor. There is a tendency to decrease horsepower and he thought that this would bring with it a reversion to four-cylinder motors in some cases. Undoubtedly the six had come to stay. The public wants a six in the same manner that it wants electrical starters and will not take any other kind and it is just the same with the six-cylinder motor.

President Marmon Favors Both

Mr. Marmon thought that the word pleasure car was a misnomer; there were two classes—pleasure cars and work cars. For those that wanted the greatest mileage for the least number of dollars the small four-cylinder filled the bill. But when the car was used for purely pleasure purposes undoubtedly the six-cylinder would remain.

Mr. Coffin thought that there was a perceptible difference in the noise of the four and six car and in the smoothness in running. It was possible to drive a six faster in traffic than a four without creating the impression of speed in the minds of others, even police officers. Undoubtedly the four-cylinder four-speed car performed wonderfully and would do as much rough work as any other. There would always be a demand for a small four, but the speaker thought that the big four would disappear. It was rather a pocket-book need than sentimentality. As far as fitting a heavy flywheel to a four-cylinder, as one of the speakers suggested, Mr. Coffin said that he did not think that this combination gave the same result as a six-cylinder motor.

Mr. Pope suggested that it would be interesting to hear members' opinions upon the advisability of fitting six-cylinder motors in trucks.

Mr. Trask stated that as the six-cylinder was a luxury he did not see that it was necessary to fit them in trucks. Further the decrease of horsepower in truck motors may also have an influence on the matter.

Mr. Riker said that with regard to the question of six-cylinder motors for trucks there were the items of economy and original cost to be taken into consideration. The matter of vibration was not so vital. In many cases in trucks enormous masses had to be accelerated and it was not a question of high gear drive all the time.

Gearbox Location Arguments

The final topic dealt with at the meeting related to the position of the gearbox. **The members were asked to express their views as to the best method; whether the gearbox forming a unit with the motor was better than when coupled up with the rear axle or was the individual unit type with the gearbox amidships better than either.**

Mr. Coffin started the discussion, stating that in his various connections in the last 5 years he had had occasion to observe the performance of cars with all the above mentioned types. In cases where the motor was coupled with the gearbox, forming a single unit, he had used both single and double universal joints and as there would be lost motion in any case he thought it was better to have as few joints as possible. When placed amidships the alignment of the gearbox is subjected to distortion through frame deflections. making numerous joints necessary, and for this reason the unit motor or unit axle types were preferable. When placed on the rear axle in the form of a unit with it there is an additional amount of uncushioned weight on the tires. He found in experience that a gearbox of this class makes it difficult to drive the car through sand and rough roads. Another objection is that it is necessary to fit both brakes on the rear wheels. When the motor and gearbox are a unit, the latter is entirely independent of any frame action. It simplifies manufacture and assembly and further reduces the number of joints and consequently eliminates lost motion as much as possible.

Mr. Marmon stated that the gearbox being placed on the rear axle does not increase the uncushioned weight any more than the addition of a demountable rim would. By placing the gearbox back a quieter drive is obtained. He thought that it was more accessible for making repairs, and further that on low gears there is less torque and it is possible to fit a long drive shaft of small diameter.

Mr. Dennison said that he built a car 2 years ago with the gearbox and rear axle in a unit and found that the car held the road better.

Mr. Riker thought that for the small power plant that the unit-motor or unit-axle types were good; but the position of the gearbox largely depended upon the power. On large cars it was better to place the gearbox amidships as it gives better distribution of weight. The reason that double chain drive cars held the road best of all was the method of weight distribution.

Mr. Brockman said that the company he was connected with has made both types and has found that when the motor and gearbox are in a unit and when any repairs are necessary it means tearing the unit to pieces.

Breaks Philadelphia-New York Record

New York, Jan. 16—The Philadelphia to New York record by motor truck of 8 hours and 45 minutes was lowered by 14 minutes today when the transcontinental Alco truck bettered its own previous best mark despite muddy going, heavy rains and thick fog.

Carrying a cargo of thirty boxes of soap, consigned by its owners, Charles W. Young & Company, of Philadelphia, to Schwarzenbach, Huber & Company, a large silk manufacturing concern in West Hoboken, the big freighter made the journey in 8 hours and 31 minutes. The load transported by the truck weighed 8,247 pounds.

Low-Grade Fuel For Motor Trucks

By N. B. Pope

Paper Read at the Winter Meeting of the Society of Automobile Engineers in New York City, January 16

¶ One truck consumes in the course of 1 year about three times as much gasoline as one pleasure car. In a broad way, therefore, the introduction of cheaper fuels for commercial vehicles should afford immediate and progressively increasing relief for the fuel market.

¶ Using gasoline, the fuel cost represents 10 per cent. of the total cost of operation. As immediate substitutes for gasoline, there are available kerosene, distillate and naphtha. There is little question of thermal equivalents in comparing these fuels with gasoline, what little difference there is being in favor of the heavier products.

¶ The bondage of the automobile industry to petroleum is largely traditional. Petroleum products must be employed exclusively as fuel only so long as they are cheaper than other fuels and both truck users and manufacturers should be brought to realize this fact.

WE are approaching a point where the stringency of the fuel market must become painfully evident to the motor vehicle user and indirectly to the motor vehicle manufacturer as well. Premonitory symptoms are: 1—continued degradation of the gasoline of commerce; 2—increased prices for gasoline, which at present are trending in a mysterious manner toward a fairly uniform advance of nearly 100 per cent. over the ruling wholesale rates of 1 year ago; and, 3—advances in the price of fuel oil east of the Rocky mountains, indicating in some measure the effect of rapidly increasing consumption for all petroleum products.

There is good reason to hope that the fuel difficulty may be relieved in large degree by cooperation between the automobile maker and the refiner, but the result of such coöperation cannot under the circumstances be realized for a period of months, possibly of several years. Its logical outcome would at best be an agreement on one or more standard grades of fuel of lower gravity and volatility than are common at present.

Meanwhile the commercial vehicle is rapidly becoming an important factor in increasing the total consumption of gasoline. **Taking a rough average of all motor vehicles in use, one truck may be said to consume in the course of a year about three times as much gasoline as one pleasure car.** Hence the great increase in commercial vehicle production must cause the motor truck to exert a preponderating influence on the fuel market as soon as the number of trucks in use exceeds one third of the number of active pleasure cars. **In a broad way, therefore, the introduction of low-grade and cheaper fuels for commercial vehicles should afford immediate and progressively increasing relief for the fuel market.**

From the user's point of view the possible reduction in the cost of fuel is far from negligible. **Using gasoline, the fuel cost represents at least 10 per cent. of the total cost of operation.** [illegible] Assuming that by the employment of low-grade fuels a saving of from 30 to 40 per cent. [illegible] could be effected and assuming the same consumption [illegible] of the low grade fuel as for gasoline, the [illegible] of the cheaper fuel would insure a minimum saving of 3 to 4 per cent. in the total cost of operation. Unquestionably the overall saving should be even greater, and by careful development of special carbureters and slow-speed motors for the purpose it is probable that the inducement to the user can be considerably increased. Indeed, one maker on the Pacific Coast, using engine distillate as fuel, claims a saving of 50 per cent. on the fuel bill and a 20 per cent. increase in power by doing away with gasoline.

PRESENT AVAILABLE FUELS

As immediate substitutes for gasoline there are available: kerosene, distillate and naphtha.

Kerosene is exceedingly plentiful, low in cost, uniform in quality, promises to continue in abundance and, if demanded in large quantities for motor fuel, could be disposed of in the domestic market with greater profit to the refiner than when marketed abroad, as is so largely done at present.

Engine distillate is a product obtained from the western crude oils after the lighter fractions have been distilled off, and, in a way, is analogous to kerosene in respect to its position in the scale of petroleum derivatives. It is less thoroughly refined, however, and at present is to be considered principally as a local product. That its practical equivalent could be produced from other asphaltic oils, such as those of Texas and Mexico, I believe to be the case.

Naphtha is as indefinite a term as gasoline. In its present use it is intended to embrace not only the heavier fractions that commonly are included with the gasoline distillation, but also the fractions between gasoline and kerosene, which are at present lost to the automobile fuel market. Being slightly more volatile than kerosene and moreover free from the doubtful reputation that kerosene enjoys as a fuel, it should prove easier to introduce, first, because the user is in no wise prejudiced against it, and second, because its employment entails less experimental development.

FUEL VALUES

In considering the comparative utility of different fuels, particularly as between gasoline and the lower-grade petroleum distillates, there is little question of thermal equivalents. **Whatever difference exists is, if anything, in favor of the heavier products.** Volatility, however, as expressing the ease with which the mixture may be generated, is of paramount importance. Volatility, viscosity and gravity together indicate the comparative facility with which a fuel can be reduced to the condition of a dry or wet mixture and so delivered to the engine.

CARBURETION

In considering the lower-grade fuels it is necessary thus to distinguish between the carburetability and combustibility. That a liquid cannot be carbureted by ordinary methods need not condemn it for use in the internal combustion engine, but it does exclude it from consideration as a fuel for automobiles of present construction. In this way it is perfectly true that the carbureter is really the determining factor in fuel selection. As the values of volatility, viscosity and gravity are lowered the fuel becomes, respectively, harder to vaporize, more difficult to force through small orifices (having a higher coefficient of discharge) and requires a greater lifting effect (suction) to overcome its superior mass per unit of volume. With the heavier fuels, therefore, different proportions must be employed in the carbureter in order to obtain results corresponding to those obtained in successful instruments designed for gasoline.

The quantitative expression for the relation of these all-important area and velocity relations is still locked in the designer's breast, but it is evident at least that a carbureter designed for heavy fuel may be more satisfactorily operated with gasoline than a gasoline carbureter with heavier fuel. To assist in the vaporization of the lower-grade fuels more heat is necessary than for gasoline. This is due largely to the fact that the latent heat of the heavier fuels is greater than that of gasoline. With the lighter fuels, such, for example, as 70-degree gasoline, a larger proportion of the fuel may be vaporized completely before the mixture reaches the cylinders. With the heavier fuels, on the other hand, most of the fuel reaches the cylinders in atomized liquid form.

The application of heat to assist the vaporizing action may be continued profitably only up to the point where volumetric efficiency is affected adversely. So long as the heat supplied to the mixture is absorbed in raising the temperature of the liquid particles, or in vaporizing the fuel, the volumetric efficiency will not be reduced, since the temperature of the mixture will not be raised; but the partial insulation of the liquid by the surrounding medium of air and fuel vapor prevents a free interchange of heat, particularly in view of the high velocities involved. For this reason the quantity of heat than can be supplied is less than that required to bring even the lighter fractions to the boiling point and convert them into vapor.

That a certain loss of volumetric efficiency can be employed profitably as an offset to the non-homogeneous and consequently slow-burning mixtures that otherwise would result is, however, probable. The law of compromise will stand considerable investigation in this respect.

High velocities likewise, while tending to promote evaporation by mechanical action on the liquid particles, can be employed only to the limiting point where the volume of the charge is reduced by excessive fluid friction. Practically speaking, both methods must be used in combination. In any case, however, it must be borne in mind that the bulk of the vaporizing process with the heavier fuels must be carried on within the cylinder during the compression period.

The design of the heavy-fuel instrument, therefore, must be postulated on the theory that it will handle at all times a wet mixture, and due provision must be made against the separation of the liquid component by baffling surfaces. Furthermore, since a certain amount of separation must occur from this cause, with consequent tendency to "loading" of the mixture under certain running conditions, its effect must be minimized as far as possible by providing ample heating for all critical points in the manifolds and ports.

STARTING

However successfully a carbureter for low-grade fuels may be made to function under normal running conditions, starting will be rendered difficult in just the degree that normal operation is dependent on heat supplied. Of the two available methods of counteracting this difficulty—one the supplying of artificial heat prior to starting and the other the use of a more volatile fuel for the first few charges—the latter is by far the simpler and easier to accomplish. Where normal carburetion is dependent largely on high velocities to convey the mixture to the cylinders, starting the motor when cold is accomplished more easily. Ease of starting thus becomes, as it were, inversely proportional to the normal heating-effect and directly proportional to the normal velocity-effect under running conditions. Hence it is reasonable to conclude that a mechanical starting device will always be required for low-grade fuel motors, and that in addition either the use of a high-grade fuel for the first few moments of operation will be necessary, or else a method of priming. In many respects the latter method is preferable, especially if acetylene be used, since it permits starting without special carbureter adjustment (other than choking of the air), simplifies bi-fuel tank and piping complication, and further introduces into the primary charges a high-velocity combustible which serves as kindling material for what is practically a normal charge.

There is every reason to believe that in the natural course of events engine-starting appliances will soon become a practical necessity on all motor vehicles, so that the development of such devices for commercial vehicles in connection with the adoption of low-grade fuels need not be viewed in the light of a special and purely incidental burden. Practically speaking, starters are more necessary on commercial vehicles than on pleasure cars, through their economic advantage in conserving the driver's energy and because they permit the shutting down of the engine for all loading stops.

COMBUSTION

On combustion the lower-grade fuels, containing as they do larger proportions of unsaturated hydrocarbons, give rise to more complex reactions than the higher-grade fuels, with consequent tendencies to the deposition of free carbon. Due to the complicated nature of the process, and on the hypothesis that certain of the reactions must proceed in sequence, flame propagation is less rapid with the heavier hydrocarbon, even with homogeneous mixtures that are properly proportioned. With incompletely vaporized mixtures, or those which are not agitated during the compression stroke and which in consequence may be described as in a "lumpy" condition, combustion will be further delayed by the completion of the mixing process as a result of the agitation of the flame waves. Because of this double retarding influence, slow combustion almost invariably accompanies the use of the lower-grade fuels, which are in consequence suitable for slow-speed motors only, so long as carbureting methods approximating those at present in use are retained. As the slow-speed engine is well adapted in other respects for commercial vehicle use, however, it follows inversely that the heavier fuels are particularly adaptable to commercial vehicle purposes.

DEVELOPMENT

As a large proportion of commercial vehicle types may be said more truly to be in the early stages of evolution than are pleasure vehicles, it follows that the adaptation of special apparatus for handling low-grade fuels will work less hardship on the truck manufacturer than it would if forced on the builder of established types of pleasure vehicle. Further, the higher valuation placed on operating economy by the commercial vehicle purchaser must tend to render the kerosene or naphtha-burning machine a more acceptable offering in that field than a pleasure car possessing the same feature would be in its field. Indeed, were it possible to offer almost any large truck user a carbureter that would handle a low-grade fuel as efficiently as his present carbureter handles gasoline, there is little question that he would accept the substitute immediately, on the basis of a not unreasonable performance guarantee.

NEED OF POPULAR EDUCATION

It will be objected that so long as the commercial vehicle user sees countless pleasure cars operated on gasoline, he will continue to be skeptical about the need or advantage of changing to a substitute fuel—even in the face of high and continually rising prices for gasoline; which is largely true. Above all things, there is need that motor vehicle users of every class be taught to discriminate in the matter of fuels—that they be taught that it is possible to offset rising gasoline prices by the adoption of lower-grade substitutes, and not improbably in the future by the adoption of manufactured fuels derived from various sources. The bondage of the automobile industry to petroleum is largely traditional. Petroleum products must be employed exclusively as fuel only so long as they are cheaper than other fuels. As a matter of self-protection the automobile manufacturer should assist in spreading this truth.

Granted the possibility of adopting a fair working standard for motor fuels, introducing one or more low-cost substitutes for gasoline, such an educational program could be readily put under way. Otherwise the process must be slower and more difficult. Let one or two successful manufacturers exploit models specifically intended for low-grade fuels, however, and the movement will be well inaugurated. What one small concern in its isolated territory west of the Rockies has done from the very beginning of its career, other and better equipped makers can do without fear of failure, and without risking a staggering capital investment. Once the movement is really started and the truck user learns that he can reduce materially his outlay for fuel without sacrifice of serviceability, the battle will be more than half won. And when the pregnancy of the present fuel situation is fully understood, the strategic advantage of such a development can be well appreciated.

Harking Back a Decade

FROM THE AUTOMOBILE of January 24, 1903:

The surprise of the 1903 show is the revelation of willingness of the American public to pay several thousand dollars each for large and powerful gasoline wagons fitted with the tonneau, either detachable or built in. Freedom of observation and display are combined in this form of self-driven carriage, and this possibility of seeing and being seen, and the sense of power and mastery which come from the control of a large and powerful and showy structure, is the secret of the popularity of the tonneau form of carriage body.

For elegance of translation and freedom from all contingencies of delay, the electric vehicle is beyond criticism.

The water-cooled hand brake on the differential, and occasionally on the countershaft as well, shows no alteration. Neither of these positions are commendable.

The committee of the Chicago Automobile Club on entertainment at the coming automobile show is busily at work. Handsome quarters will be fitted up at the Coliseum, where good cheer and other things will be on tap, with the genial Frank X. Mudd in charge. Open house will be the order of the day at the clubhouse also.

Digest of the Leading Foreign Journals

Continued Discussion of Mechanical Means To Be Adopted To Operate Automobiles With Diesel Motor Fuels—Keeping Lubricating Oil Out of the Combustion Chamber—Help for Poor Tourists—Twin Tires for Runabouts

PROSPECTS of Diesel Motors for Automobiles, II.—In last week's issue an excerpt of an article by Otto Malms of Mannheim was presented in which it was explained why and how two of the principal difficulties in applying the Diesel motor and fuel system to small high-speed automobile motors could be overcome, although they have not been overcome in practice as yet. It was shown that the problem of reducing the weight of the Diesel motor was solving itself through the lessons learned in building aviation motors and that the introduction of very small and accurately measured amounts of heavy oil in the fuel nozzle of each cylinder at a speed rate up to 12 to 15 times per second, as required for automobile motors, could be managed and, more particularly, could be managed so as to make the amount introduced for each combustion independent of the motor speed. The method proposed was that of driving two pumps, by reduction gearing from the crankshaft, in a special manner producing a continuous and constant stream of fuel from a reservoir into a pressure channel—the flow and therefore the pressure created in the channel being subject to regulation by variation of the pump piston strokes—and the method also involved taking the fuel from the presssure channel to the cylinder nozzles by means of needle valves with a cam-operated stroke on a plan shown in an accompanying illustration (Fig. 3 last week).

The author shows that with such a system the practical troubles encountered in trying to measure separately and individually the infinitesimal dose for each combustion are effectually obviated. For example, a 4-cylinder motor with a 100-millimeter stroke, giving 40 horsepowers at 1,400 revolutions per minute, requires for each power stroke in each cylinder 0.06 cubic centimeter of fuel, and a twin pressure pump of the kind proposed, which rotates 35 times slower than the motor shaft, would have to have a 35 times larger piston displacement for each pump. That is, each piston must at each stroke furnish 2.1 cubic centimeters of fuel. Accordingly, the pumps should make 40 revolutions per minute and, with a stroke of 15 millimeters should have a diameter of 13.3 millimeters—all of which comes within practicable working limits, so far as the dimensions are concerned, while the very low rotation-speeds of the cams which operate the pistons guarantees minimum wear and safe working of the suction and pressure valves. [Since in automobile practice it is not the object to produce automatically a strictly constant speed with a variable load, it is perhaps unimportant that the opening of the needle valves under the author's plan still depends for its duration upon the motor speed—in inverse proportion—and that the adjustment of the fuel pump and the resulting pressures in the fuel channel therefore cannot coincide exactly with the variations of the load. It seems to be the author's idea that the pressures will automatically take care of the feed to the cylinder nozzles through the needle valves, and this may indeed be the case if the dimensions of the needle valves are chosen so large as to admit a maximum dose of fuel in the minimum time of valve opening (corresponding to the maximum motor speed) without any larger back-pressures than are admissible in the pump mechanism. A complicated question relating to the balancing of pressures seems, however, to be involved.—Ed.]

In a later instalment of his article Mr. Malms discusses the third important difficulty in adapting the Diesel system, with its very important advantages, to automobile conditions. It relates to the atomizing of the fuel and its forcible injection in this form into the cylinder against a very high compression—a compression high enough to cause immediate ignition. So far, this has in all successful Diesel motor constructions been done by means of a compound air compressor with intermediate water cooling, the air being sent from this compressor at a pressure of 50 to 60 atmospheres to a steel storage bottle from which some of it is let loose at the beginning of each working stroke of each cylinder, thereby carrying the fuel charge before it and atomizing it by forcing it through a more or less obstructed channel. All other methods have proved faulty in practice and would prove still less available at the speed of automobile motors. [The author here enumerates the faulty methods which have been tried out and gives the reasons for their failure.—Ed.]

In a general way it may be said that the main requirement under the Diesel system is that every particle of fuel, when it is blown into the cylinder, shall find at once all the oxygen needed for its combustion, and only the injection by a stream of compressed air complies with this requirement. The important question is therefore whether the air compressor can be adapted to automobile conditions, and this is so much more decisive as a Diesel motor with its 30 atmospheres of compression cannot be started by cranking, so that the compressed air will be needed for starting purposes anyway.

COMPOUND COMPRESSOR THE SIMPLEST FOR THE WORK.

An arrangement for getting along with a simple compressor instead of a compound one takes the form of using the motor cylinder itself for the first compression, as may be done by proportioning the combustion chamber for a higher compression than is wanted and then tapping air from it to the single compressor during the compression stroke in the motor cylinder. In this manner air can be fed to the compressor at about 10 atmospheres, but this system becomes more complicated than a compound separate compressor in the case of a 4-cylinder motor, as air must be taken from all of them to make them operate alike. The number of conduits and cams required for this would seriously encumber the engine. In addition, this system, which is not much used, even in stationary single-cylinder motors, involves a loss of efficiency, as the air taken from the cylinder is at a high temperature and consequently considerably expanded.

The difficulties in designing a compound compressor to run at high speed are numerous however, and the compressor cannot be geared down, as it would become too heavy and large. They relate largely to finding room for valves of sufficient dimensions for the high-speed work and to certain troubles with the lubricating oil which finds its way under the piston rings into the partial vacuum created in the compressor.

A construction intended to overcome these troubles and meet the needs for an air-compressor in an automobile motor operated at high speed on the Diesel system, and with heavy oil as fuel, is shown diagrammatically in Fig. 1.

To get room for large valves, especially in the low-pressure portion, the two pistons are separated and are driven individually. This releases the whole top of the low-pressure cylinder for valve purposes. In other cases both pressure and suction valves are located here, but in this construction the size of the pressure valve is doubled by replacing the suction valve with slits in the cylinder wall which are uncovered by the piston toward the end of the suction stroke.

The low-pressure piston a is driven from the crank b. The knuckle c of the connecting-rod carries an arm d which, by means of a pair of rods e actuates the high-pressure piston f. Instead of this arrangement two cranks could be provided and the high-pressure cylinder could be placed in front of the low-pressure cylinder. This would make the whole engine longer, but, on the other hand, it would make it possible to balance the moving masses in the two cylinders by offsetting the cranks 180 degrees.

The high-pressure cylinder has a guide g which is incorporated in the cylinder body by means of the flange h and has a slit i in which the bolt k, projecting on both sides and secured to the ends of rods e, can slide with the piston f. The group of piston rings l is, in the highest position of the piston, underneath the slit m, so that in no position of the piston the compressed air which enters at m, coming from the intermediate water-cooling chamber, can escape along the lower portion of the piston into the crankchamber.

In the low-pressure cylinder, air enters at n at the lowest position of the piston a. It is compressed to about 10 atmospheres by the upstroke and is pushed through a group of ball valves o, whose motion is limited by a perforated plate y, into a conduit leading to the cooling device. Taken thence to the high-pressure cylinder by way of slit m it is compressed to 50 to 60 atmospheres and is pushed through the pressure valve q into a steel bottle. The unmentioned features may be as customary in the construction of Diesel motors.

Considering that the problem of adapting the Diesel system to automobile conditions is of far greater ultimate practical importance than other current motor problems and that, for example the question of the superiority of sleeve-valve and rotary valve motors over poppet valve motor dwindles to insignificance in comparison, unless it is discussed with reference to the different adaptability of these types for being operated with any and all of the fuels which can be burned in a Diesel motor, it may be of interest to look into the merits of the proposed air-compressor a little closer.

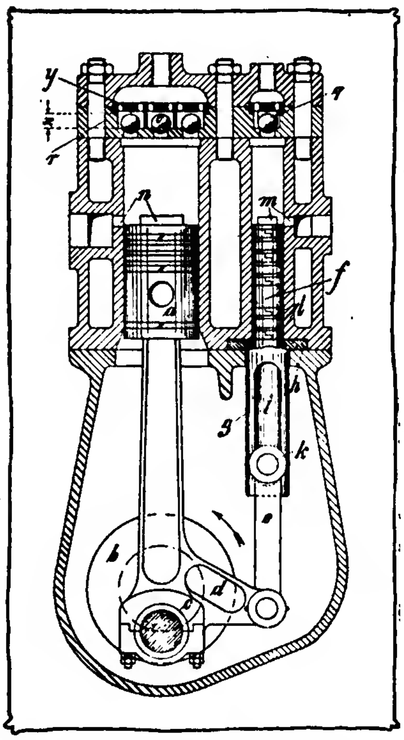

Fig. 1—Proposed compound air-compressor for automobile Diesel motors

The use of slits to take the place of suction valves has the disadvantage that a sharp depression is produced temporarily in the compressor cylinders during the suction stroke, to be relieved only toward the end of the stroke when the slit is uncovered. While experience has proved that the slit can be made large enough to assure the complete filling of the compressor cylinders with air, even at the highest speeds, it is undeniable that the tendency to vacuum formation means a small loss of efficiency, as a mean back pressure of about one-half of an atmosphere —7 pounds—has to be overcome during the suction stroke. As however the power consumption of the compressor amounts to only about 6 per cent. of the maximum power output of the motor, the loss caused by using slits instead of valves is in reality negligible. The possibility that lubricating oil may be drawn past the piston during the temporary vacuum, and that this oil may find its way into the cooling device and finally into the high pressure steel bottle, is more serious, as it may give rise to explosions in the high-pressure portions of the compressor, especially as the cooling water in an automobile motor cannot be kept at as low a temperature as in a stationary motor of low speed.

It is this possibility which is obviated in the construction shown in Fig. 1, by lengthening of the pistons and the use of piston rings at the lower ends.

WHY PISTON RINGS FAIL UNDER SUCTION

The need of this provision may not be apparent to all, as the causes which lead to leakage of lubricating oil around the pistons are not generally understood. That even in an ordinary automobile motor oil is drawn into the combustion chamber during the suction stroke seems at first blush inexplicable. A piston which remains tight under a high pressure of 25 atmospheres, as is produced an instant after the ignition of a charge, should apparently be expected to remain tight also under a depression amounting to not more than one-tenth of an atmosphere during the suction stroke of an automobile motor and to not more than one-half of an atmosphere in the proposed compressor. But the fact is that piston rings employed in the customary manner are adapted for tightening against compression only. During the compression and working strokes a small portion of the compressed air and of the explosion gases is forced into the grooves of the upper piston rings and assists in expanding the latter against the cylinder wall, so that no oil or gas can escape there. Otherwise at the suction stroke; the depression which also finds its way to the grooves back of the upper rings contracts the rings instead of expanding them, and the oil coating the cylinder wall therefore passes freely into the combustion chamber.

With the proposed compressor construction, on the other hand, the depression which may pass the upper rings is neutralized by the air entering at the intake slit, while the lower ring is protected against the effects of depression through the existence of the slit and, on the contrary, scrapes the oil on the cylinder wall back into the crankcasing. In the case of the high-pressure piston, several lower rings are provided, so that the air taken in at the suction slit at about 10 atmospheric pressures shall not escape around the piston downward to the crankcase when the piston is at the top of its stroke.

STARTING BY BY-PASSING AIR TO CYLINDER

The manner in which an automobile Diesel motor with open fuel nozzle should be arranged to facilitate starting remains to be explained. Parallel with the main channel of the nozzle another channel is provided which at its lower end opens into the motor cylinder and at its upper end can be connected, by means of a special valve, with the nozzle cavity immediately below the air-injection valve. The latter is so dimensioned and operated as to admit more air than the narrow nozzle channel will pass into the cylinder. When starting, one opens the valve to this bypass channel, with the result that a quantity of air corresponding to the full capacity of the air-injection valve enters the cylinder, filling it with air of the required compression. Such starting valves should thus be provided for each of the motor cylinders and may be opened simultaneously with a lever. If, before the compressed air is admitted, the piston in one of the cylinders is turned to a little past dead center, this cylinder will be started at once when the air is admitted, as the normal injection in that case is also timed right for the starting. After the first few turns the bypass valves should be closed, so that the pressure air will pass through the nozzle only.

Summarizing, it seems that beyond a doubt the question of whether the Diesel system can be adapted to automobile motors must be answered in the affirmative. That the work leading to this eventually inevitable result has not yet been done may perhaps be ascribed to the fact that engineers who are familiar with Diesel motors as a rule do not appreciate what the requirements of an automobile motor are, and that automobile motor engineers, on the other hand, have not had time to familiarize themselves with the history and workings of Diesel motors.—From *Allgemeine Automobil-Zeitung*, December 20 and 27.

COMMON Carrier Automobile Lines.—In France, as well as in other countries, it has been observed that enterprises organized for the purpose of offering the general public transportation by means of motor vehicles are usually launched without much knowledge of either the technical or the commercial requirements and that the average result is poor and expensive service. This applies to livery work in minor cities and country districts and especially to stage lines and touring route service.

With a view to remedying this situation the Automobile Club of France held during the recent Paris automobile salon a convention which was designated as the First Congress of Common Carrier Transportation by Automobiles and which was numerously attended at all of its meetings by persons prominent in public and business life, showing that the interest in the question was widespread.

It appeared from the information offered on this occasion that the habit of automobile owners to make frequent tours to the scenic portions of France has developed a popular desire for similar automobile touring among those portions of the public to whom the individual ownership of an automobile is either financially out of the question or does not seem advisable until some experience in the advantages of automobile travel has been gained by them. To meet this new want many touring routes have been established, while many of the motor stage lines subsidized by the state or community have derived an additional income from the new tendency and in some cases have made additions to their stock of vehicles and have extended and modified their routes. It was stated that subsidized stage service exists in 16 of the departments (counties) and received a subsidy in 1912 of 500,000 francs. The number of lines reaches at present 300, covering a mileage of 8,000 kilometers, and these are served by 450 automobiles. The service is partly all the year round and partly only for the summer season.

In Italy the subsidy plan has been taken up with considerable vim, as the premiums in 1912 amounted to 2,848,511 francs, while the lines number only 162, covering a mileage of 6,600 kilometers.

At all sight-seeing centers, it appears, the number of visitors has been increased very notably by virtue of the facilities now offered for making rapid one-day round-trips in automobile Alpen-cars or omnibuses and for connecting from one railway to another. In certain formerly inaccessible places winter sports have become fashionable through the same means.

It was a subject for comment at the congress that the vehicles placed in service are unsuited for carrying either the amount of baggage or the bicycles which the passengers wish to take along, and a resolution was adopted providing for a competition for baggage-carrying devices for common-carrier automobiles. The same resolution also expressed a desire for a contest of motor sleighs, especially with a view to developing a high-power sleigh capable of making its way under the most unfavorable conditions of the roads and of the snow.

A comparison of the expense in running three routes in the French Alps, all served with Alpen-cars seating 18 passengers each, revealed the peculiar condition that the smallest of these routes, with five vehicles, cost only 0.90 franc per kilometer to operate, while the second one, operating from 5 to 8 vehicles, cost 1.30 franc and the most important enterprise of the three, with 8 to 18 vehicles in commission, cost 1.60 franc. The operating conditions were similar, but the overhead and administration expenses grew faster than the number of vehicles employed.

The congress received a large number of communications relating to the most economical construction of common-carrier automobiles—mostly with reference to touring service—and also wth regard to financial organization and road improvements. It was brought to a close with the formation of a national federation of those most competent to give counsel in the matter of establishing public automobile services.—From *Génie Civil*, December 28.

FUTURE for Small Pneumatic Twin Tires.—"The twin construction solves the problem of the pneumatic tire for the future. At present the twin type is used only for large vehicles and it does wonders for it, speaking from my own experience. I have a car with a 4-cylinder motor, 100 by 160 millimeters bore and stroke. It is fast and weighs 1,950 kilograms without load. Single rear tires, 120 millimeters (nearly 5 inches) broad, lasted for 1,200 to 1,500 kilometers. I had it fitted with twin tires of 120 millimeters each, and these tires have made so far 5,000 kilometers. I am convinced they will make 5,000 kilometers more.

"It is said that the twin tire drags. That is true for the large widths, but what is to hinder twinning in small widths for light vehicles? Why not twin with 105, 90 and even down to 75 millimeter sizes?

"I am convinced that in a few years twin tires will be used on down to 12-horsepower cars, in 75 and 85 sizes. That will compel the use of two sizes for one car, with single 90 or 105 sizes on the front wheels, but it will involve such a saving and such a security that the inconvenience will be eclipsed by the enormous advantages.

"The twin tire is the one great improvement realized in pneumatics for some years back and it is a duty to give credit to the two firms—Kapferer and Michélin—who made its use possible by providing wheels for it.

"The only objection raised against the twin tire refers to its looks. Some people find it clumsy. As soon as it is generally used they will find it pretty."—Mortimer-Mégret in *La Pratique Automobile*, December 25.

FLUX for Autogenous Welding.—The employment of flux for cleansing and de-oxidizing the joint of an autogeneous weld was considered a useless precaution when the new art was first taken up. It was an expedient reserved for beginners and unskilled workmen. But it has now been generally adopted even for the welding of iron and extra-mild steel. As it has become recognized that the best weld is one which has been effected in the shortest posssible time, the new work methods, involving the use of fluxing powders which promote the intimate union of the metal fused by the heat of the oxy-acetylene burner, are evidently most to be recommended. Unfortunately, however, the fluxing powders are utilized in a haphazard manner at most shops, while certain precautions are necessary to obtain the maximum useful effect with a minimum waste of flux and weld-metal material.

The best way of using a flux powder consists in dipping the end of the weld-metal bar from time to time into the can with the flux and then placing the weld-metal on the line of the weld.

If the powder is suitable, the quantity of it which is applied to the fused metal by this method is sufficient to assure a sound joint. Hence it is useless to sprinkle the powder along the line of fusion, a process which nearly always results in the formation of blowholes and involves an enormous waste of the auxiliary materials.—From *Revue de la Soudure Autogène*, December.

Easy on the Hand.—Every speed lever now has a ball at the top and their manipulation is considerably facilitated thereby.—From Paris Show notes in *Omnia*, December 21.

Communications from The Manufacturer

V. A. Longaker Outlines the Advantages of Large-Diameter Wheels and The Underslung Frame

INDIANAPOLIS, IND.—The advantages of large diameter wheels are self-evident. Strange as it may seem, the only question ever raised is the one as to tire cost. The advantages of large diameter tires are so fully appreciated by the tire manufacturers that they are encouraging the use of large diameter tires by making a concession in the price. By referring to a price list of any of the large tire manufacturers, it will be found that the price of a 41 by 4.5-inch casing is less than the price of a 36 by 5. This hardly seems reasonable to the casual observer. The 41 by 4.5-inch casing must contain a greater amount of rubber and canvas, and certainly it takes a greater length of time to build the body of the tire, owing to the larger diameter. The fact that the difference in the list price is in favor of 41-inch tires can only be explained in that the tire manufacturer is endeavoring to encourage the use of large diameter tires, no doubt reasoning with his own mind that the large wheel is the only solution of the tire problem.

The perfecting of the pneumatic tire has not progressed with the rapid development of the automobile. In fact, the pneumatic tire is the weak point in the construction of the car. Anything which the car manufacturer can do to help overcome the one weak point which has had the greatest retarding effect and the one thing which has been the source of the greatest expense in the maintenance of a car, certainly deserves the attention of the progressive designer.

The theoretical reason why the 41-inch tire has a much longer life than tires of a smaller diameter is that the angle formed by that portion of the circumference of the tire where it makes contact with the road is smaller. As a result, an obstruction in the road of a given height being passed over by the larger wheel, does not cause the wheel to rise so abruptly. In other words, the greater this angle, the more quickly the wheel is called upon to rise. The blow of the contact of this obstruction is consequently greater. Owing to the increased radius of the arc at that portion of the tire which is in contact with the ground, a great many small depressions in the road can be bridged. If the wheel was to drop into these depressions, the fall would result in practically the same kind of a blow being applied to the tire as if it were passing over an obstruction which stands above the surface of the road. The greater number of these small, but nevertheless telling, blows that can be overcome will not only prolong the life of the tires, but will also result in the entire mechanism of the car being greatly protected.

Vibration Must Be Minimized

Vibration in itself can in a way be compared to a great many blows of greater or less magnitude being applied with greater or less rapidity. The blow of a hammer, for instance, no matter how small it may be, if kept up sufficiently long will destroy the best piece of armor plate. Vibration is the greatest enemy the motor car of today has to contend with. The large wheels not only lengthen the life of the tires, but prolong the life of the rest of the car as well. In early automobile construction this important factor of vibration was not as fully appreciated as it is at the present time. The early builder found that certain parts of his car were failing. In his early calculations the part may have been designed with the factor of safety in view; however, the all-important question of vibration was overlooked. This problem of vibration has created the demand for the alloyed steels which enter into the construction of the automobile of today to such an extent.

Another reason why the large diameter tire will give a greater mileage is that the length of the cord which is formed by the surface of the road depressing the periphery of the tire is much greater; for instance a 36-inch tire having a 5-inch section, properly inflated (89 pounds), will have a contact surface in the form of an ellipse approximately 1.75 inches in width by 7.5 inches in length. The area of contact of the 41-inch tire, properly inflated and carrying the same load, is approximately 8.5 by 1 15-16 inches. The area of the first contact surface is 10.3 square inches, and the second 12.3 square inches, or a gain of 20 per cent.

The increased length of the contact with the road not only has its advantage in the surface wear of the tire, but also plays an important part in the ability of the tire to withstand the enormous strains which are applied in the driving and the retarding of the car to that portion of the tire which is in contact with the ground. The reason for this is that there is a greater per cent. of the periphery of the tire which is carrying the load, and owing to the load being applied over a greater portion of the tire, the strain is more equally distributed.

Keeping the Car Low a Problem

The ideal condition as far as the load being applied to tires is concerned, would be to distribute the load throughout the whole circumference. This, however, is absolutely impossible, consequently anything that can be done to increase the amount of the surface of the tire which is carrying the load will certainly tend to improve its wearing quality. The most important reason why automobile manufacturers have been averse to the application of the large diameter wheels is that when these wheels are used in the construction of a car having an overslung frame, owing to the assembly problems which are encountered, the car by necessity is decidedly higher. From the viewpoint of safety as well as the idea the buying public has today, a car must be low in order to be acceptable. The thing which determines how low a car can be built is the road clearance. In the construction of our underslung cars we have four all-important advantages: large wheels; a maximum road clearance, 12.25 inches, which is from 2 to 3 inches more than the ordinary car of today has; and although the maximum prevails as to these two important questions, the total assembly of the mass of the car is well down, for instance, the greatest vertical height of our Traveler is 4.5 feet; the center of gravity of the mass being decidedly low, approximately 23 to 24 inches. The combination of these four very important details results in a car having the greatest possible amount of stability. Where else is it possible for the prospective buyer to find these four important features embodied in the construction of one car?

In traveling around a corner at a high rate of speed in the ordinary overslung car, the driver experiences a sensation as though the car was trying to turn over. The reason for this is that the center of gravity of the car is so high that the springs are called on to carry a much greater additional vertical load, owing to the fact that the mass of this load is so much higher than the horizontal plane in which the springs lie. As a result, the outside springs deflect or flatten out and the frame of the chassis is thrown on a decided angle with the wheel centers.

In our underslung construction, although the corner might be turned at a much higher rate of speed, there is not the faintest indication of this sensation of the car turning over. The reason for this is that in the construction of the car we have overcome the causes as outlined above. The springs, being so nearly in the center of the mass of the car that the effort applied by the centrifugal force caused by the change in the direction of the car, are so near in line with the horizontal center of the mass, that instead of being deflected vertically, the load is applied to the side of the springs. As it is impossible to bend a spring sidewise, the frame of the car is held in an absolutely horizontal position, entirely relieving any sensation of overturning.—V. A. Longaker, *American Motors Company.*

Carburetion

by Robert W. A. Brewer

Part VI

Subject Digest

Inertia is one of the most important factors in the function of the carbureter for the reason that conditions of rest and motion of the gases are continually changing.

The inertia of a body varies directly as its mass and therefore the inertia of a cubic foot of gasoline is nearly 600 times that of a cubic foot of air. The smaller the quantity of gas which is operated on by a change of throttle position, the less will be the total inertia of the gas in question. A small orifice is therefore a factor in reducing total inertia.

High jet friction is another means of reducing the inertia of the fuel. This condition can be obtained by making the full orifices many in number.

Unless there is a considerable negative pressure at the time of the inlet valve opening the explosive mixture hesitates before entering the cylinder and follows the piston only when the latter is in the quicker part of the stroke.

Surging within the intake pipe occurs at low engine speeds giving rise to irregularities in the action of the carbureter and causing the gasoline at times to blow out of the carbureter air orifice.

WE will first set down the definition of the word inertia so that we may be quite clear upon this point.

Inertia is that property of a body by virtue of which it tends to continue in a state of rest or motion in which it may be placed, until acted on by some force. **Of all the details of an automobile engine the carbureter and the carbureting system is most sensitive to the question of inertia,** for the reason that conditions are continually and rapidly changing, and that the masses of air and gasoline which are dealt with are subject to inertia all the time the engine is working. Were an engine working at a constant load and speed throughout the whole time, the question of inertia would not come in, but as this is not the case we will briefly consider the effect of inertia, both of the air and gasoline, and of the moving parts where an automatic carbureter is concerned.

First let us consider what occurs when the throttle valve is opened and we shall see that, whereas both the air and the gasoline were previously in a state of comparative rest, we immediately impress a force upon them by reason of the engine suction, and the forces which are required to accelerate a given mass in a given time to any different velocity are in proportion to the velocity.

Repeating Newton's second law, "uniform acceleration is produced by any constant force, the latter being measured by the increase of momentum it produces," the force producing an acceleration is equal to $\frac{W}{G} \times F$, where W is the weight of the body G is gravity and F the acceleration, and the final velocity of the body, say V, equals $F \times T$, that is, the velocity V is equal to the acceleration multiplied by the time during which the acceleration acts. Now every body has an inherent quality or inertia by which it tends to resist a change of velocity, and we have, in the case of air and gasoline, two bodies whose inertia is widely different, as the mass of air is nearly 1/600th of the mass of gasoline, or, in other words, **a cubic foot of gasoline weighs nearly 600 times as much as a cubic foot of air.**

In a carbureter system, however, only small quantities of gasoline or air are set in motion by any change of throttle position and engine speed. The smaller the quantity of gasoline which is immediately operated on by a change of engine suction, the less will be the total inertia of the gasoline in question. For this reason **it is advisable to have the gasoline passage between the float chamber and the jet orifice as small as possible,** so that there will not be more appreciable lag than possible when the engine demands an increase in gasoline supply. On the air side, however, the inertia experienced is very slight by reason of the magnitude of the air aperture compared with the fuel aperture, and the immediate result of throttle opening is ordinarily a poor mixture, as the air enters the mixing chamber more readily than does the fuel. Conversely, when the throttle is quickly shut down there is always the tendency of the fuel to continue flowing by reason of the inertia of the fuel in its passage, the result being that a loading up is likely to occur.

It is, nevertheless, possible to design the passages of such small dimensions, and to arrange the friction of the orifices to be so high, that inertia can almost be damped out. **High jet friction is therefore one of the means of counteracting the inertia of the fuel.** This can be obtained by making fuel orifices many in number, as in the Polyrhoe carbureter by giving either a very small unobstructed hole for the fuel supply or a hole of larger dimensions in which some medium is interposed for producing high jet friction.

The question of jet friction plays an important part, as may be supposed, in the question of the inertia, but this may also be complicated by the phenomenon of capillarity, being the tendency for a liquid to creep up a small orifice in a contrary direction to that which it would normally take under the action of gravity. **Capillarity often causes a carbureter to leak** by reason of the liquid either creeping up through the jet or up the stem of the valve which at its lower end dips into a fuel reservoir. This action has caused considerable trouble in certain types of carbureters.

Passing from the carbureter now to the inlet pipe, inertia is an important factor in the design of inlet pipes for all types of engine, whether they be of the single-cylinder or of the multi-cylinder pattern. When we consider a four-cylinder engine firing on the usual system, namely, 1, 3, 4, 2, turbulence is set up in the inlet manifold and this turbulence is further aggravated by the inertia of the explosive mixture passing through that manifold. In such a type of pipe, particularly if the ends terminate abruptly, there is always the tendency for the fuel to load up the outer ends of the pipe, by reason of the two cylinders in one pipe firing in sequence and then the two cylinders of the other pipe. The gas feeds rapidly, first toward one end of the pipe and then toward the other, and the gas flow lags behind the cylinder demand, so that when the inlet valve of either end cylinder is suddenly closed the gas continues to flow down the pipe and banks up with increased richness at the ends. Considerable difficulty has been experienced, particularly in the older patterns of engines, by reason of **the end cylinders getting a different consistency of charge from that which is supplied to the**

middle pair of cylinders. In special designs of inlet pipes for racing cars, great care is often taken to overcome the inertia of the mixture in the pipe, and a continuous flow path is given to the bases by means of either figure-of-eight inlet pipes or circular pipes, so that the gas flow is constant and uni-directional the whole time.

Another effect of the inertia of the incoming mixture is that at the moment of inlet valve opening, unless there is a considerable negative pressure, or pressure below that of the atmosphere, in the cylinder at the time of valve opening, the explosive mixture hesitates before entering the cylinders, and it is only when the acceleration of the piston puts a more or less sudden increase of suction upon the mixture that the mixture itself follows in behind the piston.

It may occur in some engines that a negative pressure of as much as 5 pounds per square inch is momentarily produced somewhere about half-piston stroke, or rather later, before the inertia of the explosive mixture is overcome. After this time the mixture rapidly follows up, and advantage can then be taken of the inertia by retaining the inlet valve open for some considerable time after the outer dead center has been reached.

American practice generally keeps the inlet valve open later than European, as in American design this valve is often held open for some 40 degrees after the outer dead center has been reached. In European practice, however, such a late closing of the inlet valve is seldom found, and this is probably due to the fact that in Europe the valves are of larger diameter.

From the figures previously given it will be evident that **the inertia has a considerable effect upon the carbureter action by reason of pulsations being set up in the inlet pipe,** due to the suction which is necessary to overcome the tendency to lag, but in a high-speed engine these variations usually balance out. Whether they do or do not depends on the length and design of the inlet pipe.

A theory has been propounded that there is a considerable surging effect in the inlet pipe of the majority of engines. This surging undoubtedly occurs at low speed, as has been observed in certain types of carbureters where it has been shown that at certain periods the suction decreases altogether, and the inertia of the gases in the reverse direction after the moment of valve closing causes the gasoline to blow back out of the air orifice of the carbureter.

There is one other point which might be briefly referred to in passing, and that is the inertia of the exhaust gases. We are not, however, dealing with the design of exhaust pipes, but it is interesting to note that **an exhaust pipe can be so designed that the inertia of the gases passing from one cylinder helps to accelerate the exhaustion of the next** by reason of the inertia effect of these gases leaving the end of the exhaust pipe and causing a partial vacuum in the pipe itself. One has sometimes observed a certain amount of suction during the pulsation at the end of an exhaust pipe, and this is entirely due to the scavenging effect due to the inertia of the exhaust gases themselves as they pass out of the exhaust pipe.

Finally, we will, for a moment, touch upon the inertia of moving parts in a constant suction type of instrument, and it will be obvious that when these moving parts depend for their weight upon the depression they produce in the mixing chamber of a carbureter, **the weight of these parts themselves must give them a certain amount of inertia.** The quality termed pick-up, which is often mentioned as a feature of certain carbureters, is also a function of the inertia of the moving parts, for it is obvious that if a throttle be suddenly opened, and a moving part which actuates the fuel and air supply lags and does not immediately respond, the engine does not get away so rapidly as it otherwise might. In the first place, **the engine revolutions must increase to a certain extent before they can produce the necessary suction in the mixing chamber, and then this suction has to operate for some appreciable time upon the moving part before it overcomes this inertia.**

In cases where a spring or other means is employed, in which the question of gravity does not come in to so great an extent, one might think that the inertia of the moving parts would be less, but, as previously explained, a spring is not a desirable feature to perform any definite function in a carbureter system, and should, if possible, be avoided.

Prize of $10,500 Offered for an English Home-Produced Fuel

LONDON, Jan. 2—A prize of $10,500 has been offered by the Society of Motor Manufacturers & Traders for a home-produced fuel, obtainable in sufficient quantities and which can be put on the market and sold at a commercial price. Much has appeared in the press of late concerning the prohibitive prices that have long prevailed for gasoline and there is talk of still higher prices.

The Royal Automobile Club will conduct trials and tests of any new fuel produced, but at the present time, owing to the heavy expenses that it has incurred since taking over its magnicent clubhouse, it is not in a position to bear any financial responsibilities. The chairman therefore suggested that the Society of Motor Manufacturers & Traders might gainfully devote a portion of the profits reaped from the Olympia Automobile show to encourage research and experiments. The Society has announced that it is prepared to offer a prize of $10,500 for a fuel that is produced in Britain. It will, therefore, be interesting to note that at the present time there is in England, apart from the shale industry, which is being pursued with success in Scotland, two separate plants which are producing a suitable spirit from coal mines and which will, in the near future, place on the market a fuel not only suitable for pleasure cars, but also for commercial vehicles at a much cheaper rate than gasoline.

Tests have been made with a paraffin carbureter with a view of ascertaining what results would be achieved when running on the heavier, but cheaper, fuel. A run of 2,000 miles was made with this carbureter fitted to a pleasure car, which covered a great portion of the distance on the road under ordinary conditions, and also a part was run off on the Brooklands track at high speeds, and the results were entirely satisfactory, the spark-plugs being quite clean. In addition to this test, accompanied with bench and speed tests, it was fitted to a 3.5-ton commercial vehicle of 18 horsepower equipped with solid tires for a distance of 1,000 miles, in the course of which neither spark-plugs nor engine were cleaned in any way nor were the valves touched; but all were in perfect order at the end of the test, and the exhaust vaporizer was found to be entirely free from carbon deposit. The great drawback, however, when paraffin is used in the motor, is the unpleasant smell that it creates, and but for this there is no reason why it should not be universally utilized for internal combustion engines.

Then there is benzol. There are many who advocate the use of benzol for cars, but in England there are no more than 2 or 3 firms at most which produce benzol, and what they do produce is mostly sent abroad. When mixed with alcohol not only does it make a fine fuel, from which many declare a greater mileage is obtained, but it is also a very cheap one, for, compared with gasoline, it costs only 24 cents per gallon against 37 cents per gallon now asked for gasoline.

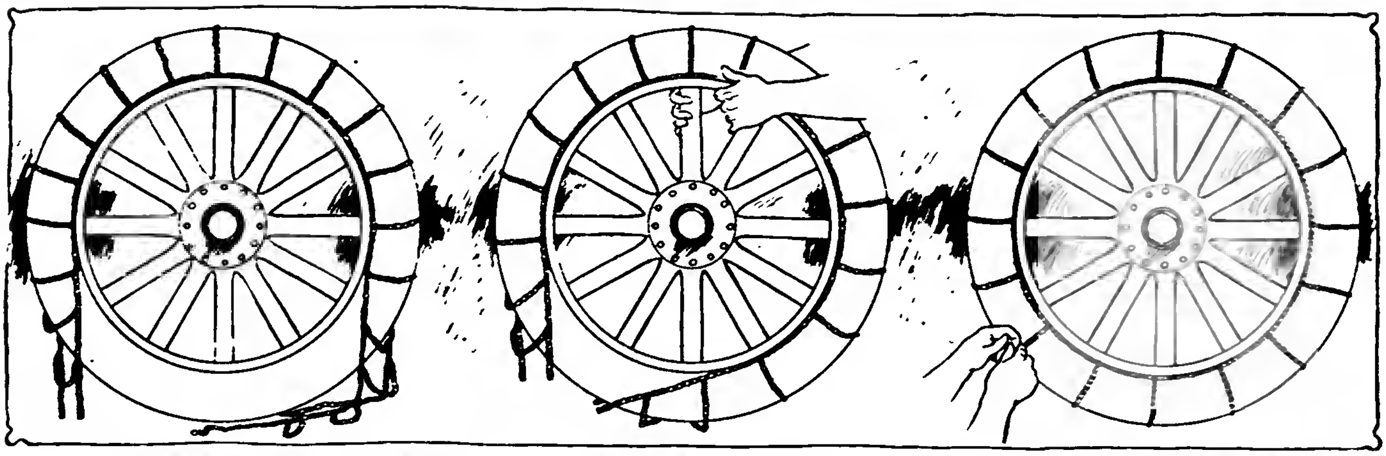

Fig. 1—Three steps in putting on a chain: First, lay chain over tire; second, pull car back over chain; third, fasten catches. This avoids use of jack

Tour from Columbus to Mammoth Cave; Carbonic Gas in Tires; Rating Six-Cylinder Cars; Making Magneto Change; Piston Displacement vs. Horsepower; Leak at Spark-Plugs Cured; Correct Oil for Winter Use

From Columbus to Mammoth Cave

EDITOR THE AUTOMOBILE:—I, with possibly forty to fifty people, expect to go by machine to Mammoth Cave, Ky., from Columbus, O. Could you give me the best route?

Baltimore, O. E. E. HANSBERGER.

· THE AUTOMOBILE suggests that you go through the following cities: Indianapolis, Ind., Louisville, Ky., and thence to Mammoth Cave. Starting out from Columbus to Indianapolis via the National Road, you will find a very level country, mostly excellent gravel pikes. The first city between these two points will be Springfield, O., a distance of 43.4 miles. By following the Blue Book route you will pass through the following towns to that city: Alton, 9.4 miles; West Jefferson, 14.4 miles; Lafayette, 21.8 miles; Somerford, 26.5 miles; Vienna, 32.9 miles, and Harmony, 37.5 miles, thence to Springfield. From this point to Donnelsville, 51 miles, crossing the railroad tracks at Forgy station, thence direct through covered bridge, 55.7 miles, through Brandt and Fountaine, Tadmor into Vandalia. From here continue straight ahead through covered bridge to Englewood. Cross the railroad tracks at grade immediately beyond and follow telegraph poles through Arlington, cross railroad track again at National Crossing and second railroad crossing to Lewisburg, 84.4 miles. Keep on the National Road through several prominent four-corners to Gettysburg, 93.3 miles, and straight ahead to Richmond. From here the following towns will be passed through: Cambridge City, Knightstown, Greenfield, thence into Indianapolis. The distance between Indianapolis and Louisville is 123.4 miles. The most direct route is via Seymour, Uniontown, Scottsburg, Vienna, Underwood, Henryville, Memphis, Sellersburg, New Albany into Louisville. From here the first part of the route is over macadam road; the last part being the old State Road, which is rocky and rather poor, a distance of 116.2 miles. Then proceed through Mount Washington, Bardstown, Buffalo, Bear Wallow and thence into Mammoth Cave.

Carbonic Acid for Tires

Editor THE AUTOMOBILE:—I wrote you some time ago in reference to the effects upon tires that are inflated from tank carbonic-acid gas. I am looking for a suitable tank to place in a private garage and the above was recommended to me. Kindly give your views on same.

New York City. A SUBSCRIBER.

—Carbonic-acid gas is very convenient and is cheap. It has the drawback, however, that it escapes from the tire through the pores of the rubber much more quickly than does air. Even air, when it is put in a new tire, will pass through the pores of the rubber much more quickly than it will after several refillings. The reason for this is that the air is made up of a combination of several gases. Those having the largest percentages are oxygen and nitrogen. Oxygen passes through the rubber pores much more rapidly than does nitrogen. As a result, after a time the air remaining in the tire contains a larger and larger percentage of nitrogen and hence remains in the tire for a greater length of time without passing through the pores. Every tire is really a small nitrogen factory. As far as harming the structure of the rubber is concerned, the carbonic-acid gas will do no harm.

Horsepower Rating of Sixes

Editor THE AUTOMOBILE:—A six-cylinder motor, bore 4 inches, stroke 5 inches, with valves in the cylinder heads, is installed in a certain car. The following questions are involved in its installation:

1. What is the A. L. A. M. horsepower rating of a six-cylinder motor of 4-inch bore and 5-inch stroke, it being an L or T-head motor, at 800 revolutions per minute, at 1,000 revolutions per minute, at 1,200 revolutions per minute, at 1,400 revolutions per minute, at 1,500 revolutions per minute, at 1,600 revolutions per minute, at 1,700 revolutions per minute and at 1,800 revolutions per minute?

2. Does a motor with valves in the head of the cylinders, everything otherwise being equal, develop more power than a L or T-head motor, and if so, how much per cent. more?

3. In rating the horsepower of a motor, does the A. L. A. M. take into consideration the stroke of the motor?

4. Does a motor having 1 inch more stroke than bore (4-inch bore) develop more horsepower at certain specified speeds than a motor having no more stroke than bore, everything otherwise being equal, and if so, how much more?

Chicago, Ill. JULIUS STRAPONIUS.

—1. The horsepower rating of six-cylinder motors is shown in the curve at Fig. 2. The A. L. A. M. or S. A. E. horsepower formula is $\frac{D^2N}{2.5}$, where D is the cylinder diameter, N the number of cylinders and 2.5 a constant. With the motor you mention, the formula would work out as 38.4. The actual horsepower developed by such a motor would be greatly in excess of this. The number of revolutions per minute does not enter into the A. L. A. M. formula, which takes a piston speed of 1,000 feet per minute as a basis.

2. This is a mooted question. With the valve in the head, a very advantageous shape of combustion chamber can be secured, and a gain in power has been claimed on this account. This gain has never been reduced to figures.

3. Indirectly. THE AUTOMOBILE has previously published the derivation of this formula, but since it is a matter of common interest, as many states use the formula as a basis of the calculation of horsepower in deciding the license fee, it will bear repetition.

The indicated horsepower of a four-cycle single-cylinder motor is equal to the mean effective pressure P times the area of the piston A, in square inches, times 1-4 the piston speed S in feet per minute and the result is divided by 33,000. The factor 1-4 holds good for the four-cycle motor since the power is only exerted on every fourth stroke or once for every two revolutions. This is expressed in equation form thus: $I.H.P. = \frac{P \times A \times S}{4 \times 33{,}000}$. Multiplying this by the number of cylinders N of the motor and further taking into consideration E, the mechanical efficiency of the motor, the formula for B.H.P. becomes: $B.H.P. = \frac{P \times A \times S \times N \times E}{33{,}000 \times 4}$. The A. L. A. M. assumed that the motor will deliver its rated horsepower at a piston speed of 1,000 feet per minute and that the mean effective pressure in the cylinder of the automobile motor will be 90 pounds to the square inch. It also assumed that the mechanical efficiency of the motor will be somewhat in the neighborhood of 75 per cent. and will average that figure. Substituting these values in the formula for brake horsepower and also substituting for A its equivalent, .7854 D^2, the equation reads: $B.H.P. = \frac{90 \times .7854D^2 \times 1{,}000 \times N \times .75}{33{,}000 \times 4}$. Performing the indicated operations, the formula is simplified to its final form $B.H.P. = \frac{D^2N}{2.489}$, or, in round numbers, the denominator may be called 2.5.

4. A motor with 1 inch more stroke than bore will develop more power at all speeds than a motor having the same stroke as bore. In the case of a motor with a 4-inch bore this ratio would theoretically be about 20 per cent. greater.

Making Magneto Change

Editor THE AUTOMOBILE:—I wish to put a Bosch magneto DR4 on my car, which is equipped with a Remy type S. Could Bosch be connected to Remy coil, so I could use batteries for cranking? If not, how would you suggest to do the work? There is no timer on the car and I can use but one set spark-plugs.

Birmingham, Ala. READER.

—The Remy S magneto is of the low-tension type and conducts a current to a non-vibrating coil which creates the high-tension current necessary for the ignition. This magneto has a stationary winding which simplifies the construction, eliminating revolving wires, carbon brushes and all moving contacts—common objectionable features of construction in other magnetos. A single winding of coarse magnet wire is imbedded in the pole pieces of the magneto. The rotative part or inductor is a solid steel shaft upon which are mounted two simple forgings or inductor wings, one on either side of the winding. At each half turn of the inductor, the direction of the flow of the lines of magnetic force through the winding is alternately reversed, inducing in the winding two electrical current waves or impulses for each complete revolution.

The stationary winding is directly connected through the magneto circuit breaker with the primary of the non-vibrating step-up transformer coil used with the magneto. The circuit is mechanically broken during the current wave which is of considerable duration (over 45 degrees of the inductor's revolution). The nature of the wave, due to careful design, is an almost abrupt rise and fall with a flat top, making possible the large timing range for advance and retard of spark at practically the same heat of spark. The timing of the spark is accomplished by shifting the circuit breaker around the inductor shaft, to which is attached the circuit-breaker cam.

The distributer of the magneto and its 2:1 driving gear for the four-cylinder motor is for the purpose of distributing the current after it has been sent to the coil and transformed to the high voltage which it is necessary to use at the spark-plugs. It will be noted that the one high-tension cable leads from the coil to the distributer. For each revolution of the magneto inductor, this cable carries two high-voltage current impulses to the distributer, and as the fan-shaped distributer segment is making one revolution to two of the magneto inductor, it can in turn deliver a

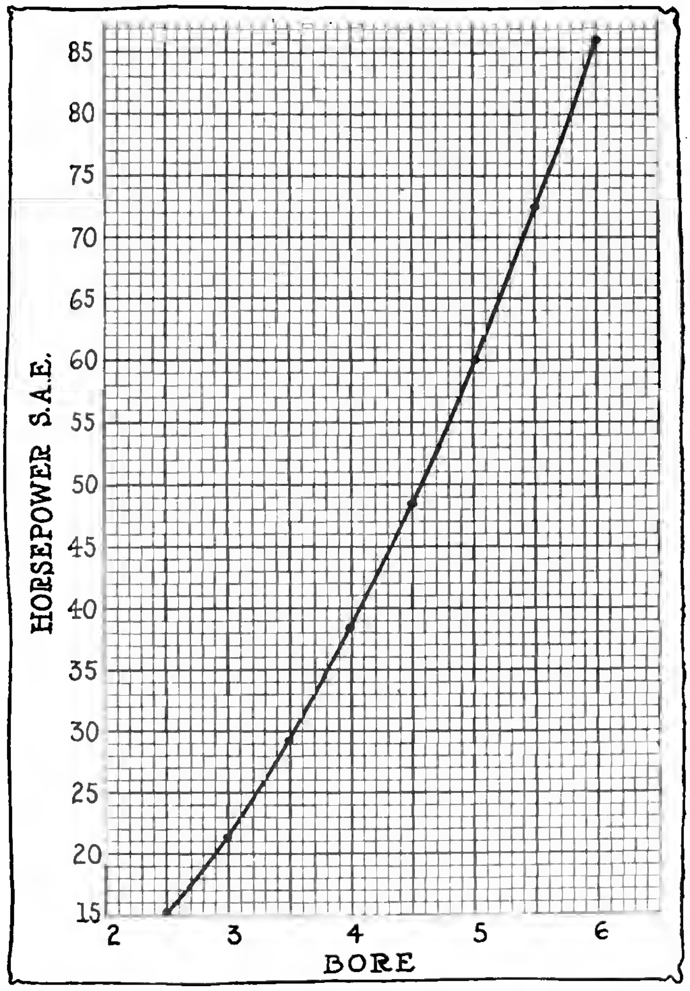

Fig. 2—S. A. E. horsepower curve for six-cylinder motors of bores between 2.5 and 6 inches

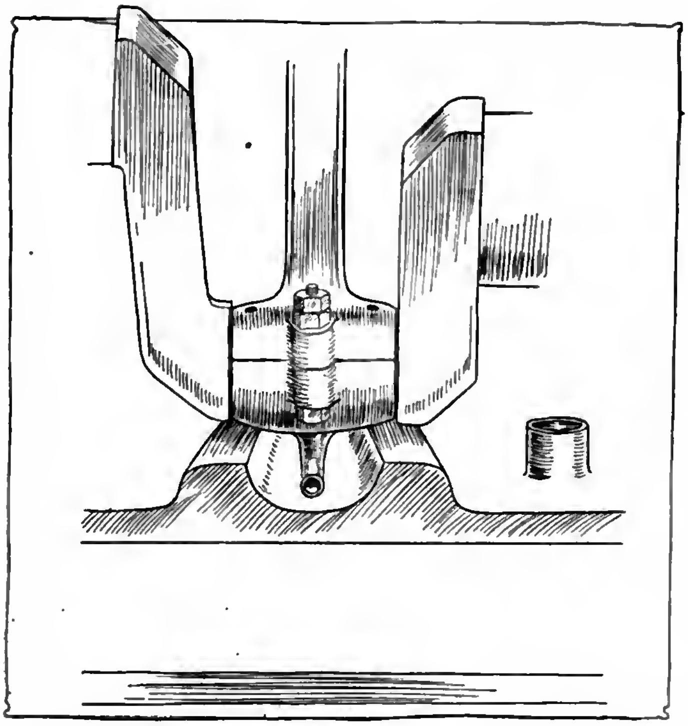

Fig. 3—Scoop on bottom of connecting-rod, illustrating splash system

spark to each of the four cables leading from the distributer to the spark-plugs each time the magneto inductor makes two complete revolutions.

The magneto inductor must, therefore, with the four-cylinder, four-cycle engine, always be driven at twice the speed of the engine camshaft or the same speed as the crankshaft. With the six-cylinder, four-cycle engine the magneto distributer is back geared with a ratio of 1:3 and the magneto must be driven at three times the speed of the camshaft or one and one-half times the speed of the crankshaft.

With the two-cylinder, four-cycle opposed engine the magneto does not have a distributer and a single cam is furnished on the magneto, causing but one electrical impulse for each revolution of the magneto inductor. The magneto must then be driven at the same speed as the crankshaft of engine.

The special step-up transformer coil furnished with the magneto is fitted with a two-point switch used to switch from battery to the magneto or *vice versa*, or disconnect from either to stop the motor. The switch is also provided with a push button for the purpose of starting the four-cylinder or six-cylinder motor from the spark by pushing the button when the switch lever is turned to the battery side. This system makes starting without

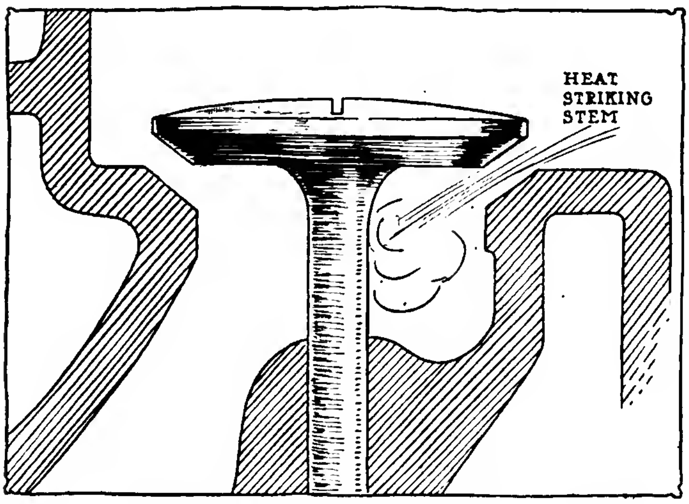

Fig. 4—Where the heat strikes the valve stem in exhausting

cranking most reliable, for the reason that the coil is particularly suited to the magneto which is not injured by large current consumption, as would be the case were batteries regularly used. When the battery is in use with the coil, it furnishes then an exceptionally hot spark. When the battery is used, it will be understood that the battery current is simply turned through the coil and distributer of magneto instead of the magneto current. It is intended that batteries be used for starting and relay, although the magneto is regularly used for starting.

The Bosch DR4 magneto is of the high-tension type and therefore it is not necessary to use a high-tension coil. The connections between the two units of the Remy system are such that the Remy coil would not even be applicable to the low-tension magneto. This is true of any of the low-tension magnetos which has been specially designed for a certain coil. No other coil would be suitably substituted.

Piston Displacement Vs. Horsepower

Editor THE AUTOMOBILE:—Will you kindly advise me if a square cylinder and one with a small bore and long stroke, both having the same amount of cubic inches, would have any difference in power.

Syracuse, N. Y. HOWARD K. BROWN.

—The motor having the greater number of cubic inches of piston displacement per minute would have the greater horsepower. In other words, it would largely be a matter of rotative speed. So many factors enter in which qualify this statement, however, that it cannot be given as any more than a general rule. The valve sizes affect the power to a large extent and the stroke-bore ratio must not be extreme. It would be possible to have a long cylinder of a stroke-bore ratio of such size that it would be impossible to secure good efficiency. For every bore and every piston displacement there is one stroke-bore ratio which would develop the greatest power when all other conditions are the same and hence it is impossible to give a fixed and definite answer to your question.

Has Leaky Spark-Plug

Editor THE AUTOMOBILE:—How can I stop a leak from my pet-cock on the engine of an Oakland 30? One of my spark-plugs leaks also.

2. When I put my machine in garage for the winter I dropped kerosene and cylinder oil in the engine. Will it be dangerous to start the motor in the spring?

Portland, Maine. P. E. BALDWIN.

—1. If you will dip the threads of the pet-cock in shellac of a fairly thick consistency and place a copper-asbestos gasket beneath the shoulder of the cock and screw it in, the leak will be stopped. If there is no shoulder leave out the gasket. Leaky spark-plugs often occur because a plug with sufficient shoulder width is not purchased. The standard A. L. A. M. spark-plug thread is a straight thread and needs a shoulder and a gasket to hold it against leakage. The other threads were taper fits and did not need the gasket. The effect of the gasket and shoulder is brought out in Fig. 6.

2. No, it will be difficult.

Connecting-Rods in Oiling Systems

Editor THE AUTOMOBILE:—On my care I have a force-feed oil system which I wish to change to the splash system. I can secure a crankcase which will adapt itself to my motor perfectly and I would like to know if it is necessary to redesign any of the bearings or the connecting-rods in order to take care of the change. Would you kindly explain to me the difference in the internal features of a splash and force-feed system in Letters Answered and Discussed?

2. What is the best way to put on tire chains quickly, without jacking the car?

New York City. CHARLES PEINE.

—Differences between the connecting-rods and crankshafts in the splash and force-feed systems are shown in Figs. 3 and 5. A small part of the crankcase is also shown. It would not be advisable to fit a splash feed on a car that is already equipped with force feed. The force feed should give satisfaction as long as the oil pump is in working order, and these are so simple that it is hardly possible that the pump on your car is out of order permanently. The only difference between the connecting-rods in the splash and the force-feed systems is that the splash connecting-rods generally have scoops to take up the oil.

2. The three steps necessary in putting on a tire chain without jacking up the wheels are shown in Fig. 1. It is important to straighten out the chain thoroughly.

Where Heat Strikes Valve Stem

Editor THE AUTOMOBILE:—Would you kindly tell me why it is necessary to select a particular material for a valve stem, when the head is the only part exposed to the heat?

Boston, Mass. H. W. PERRY.

—The heat strikes the valve stem even more effectively than the head, because it strikes it in one particular point. Therefore it is necessary to select a material that will stand up under heat which is more severe at one point than another.

Stopping Leaks in Spark-Plugs

Editor THE AUTOMOBILE:—Will you kindly inform me as to how I can stop an air leak in one of my spark-plugs? I have a Ford machine and the defect must be at the thread of the spark-plug hole in cylinder head, because of having tried a half dozen new plugs already, screwed down as close as possible, without getting any better results whatever. Is there anything that can be used on the threads to stop this leakage without causing trouble whenever it becomes necessary to take the plug out again? Would it be an advantage to have the spark-plug gaps opened less than .03 inch with the Ford magneto?

Easton, Pa. WILLIAM F. BECK.

—Referring to Fig. 6 it will be seen that a plug with a shoulder will often stop a leak. If the plug is dipped in thick white shellac before being screwed to the cylinder it will probabaly hold against leakage. The spark-plug used on the Ford car is the .5 inch. straight-thread type. Where the taper-thread spark-plug is used the threads are jammed together on account of the wedge action. Where the straight thread is used it is necessary to guard against leakage by the use of shellac or adequate gasket protection. The maximum a spark-plug gap should be open is .03 inch with the Ford magneto. It would be of no advantage to make it less and it would be bad to make it greater.

Increasing the Motor Power

Editor THE AUTOMOBILE:—In your issue of January 2, page 45, there is an article on a compressed-air motor booster, and in reading this, I thought it might be possible to increase the power of a two-cylinder, opposed motor by admitting the gas mixture into the crankcase and discharging the gas mixture into the cylinder when greater power is desired.

It seems to me that this could be accomplished by having a three-way valve arranged in the intake so that for ordinary running the engine would receive its gas in the ordinary way by suction, and when increased power is desired, the gas could be admitted into the crankcase, which would super-charge the cylinder to a considerable degree since we have the displacement of both cylinders for one charge of gas to each cylinder.

I have a two-cylinder Maxwell, and for some time have thought of making such a change in the intake as an experiment, but have feared that it might interfere with the proper working of the engine and for that reason have hesitated to do so.

Grafton, W. Va. R. H. P.

—It must be remembered that the compression of the crankcase on an average motor is only about 3 or 4 pounds. The expansion required to bring the gas from the crankcase into the cylinder would be enough to reduce the compression to a large extent and would therefore result in a very slight increase of power. There is no doubt but that the use of a fuel compressor which would inject the mixture under high pressure into the cylinder would increase the power. The only trouble is the greatly increased complication in the high cost of manufacturing a system which would contain the high pressures without leakage. In other words, it would be cheaper to increase the power by buying a larger engine.

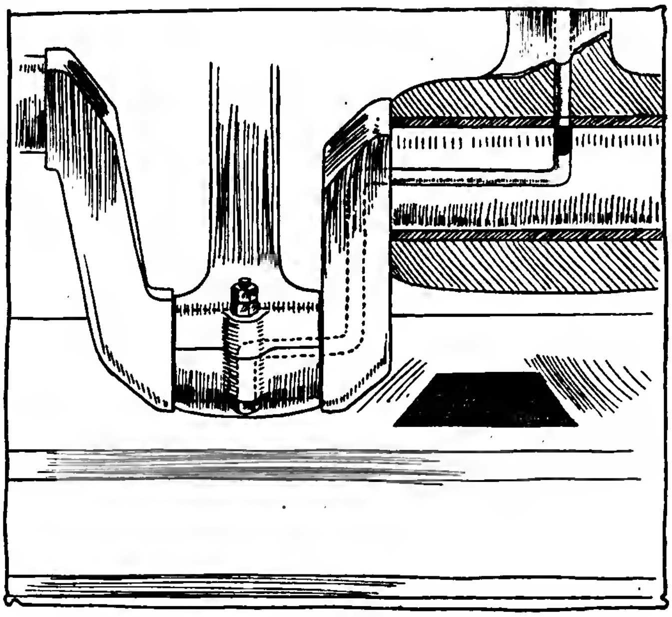

Fig. 5—Non-splash system with screen through which oil may drain

Correct Oil for Winter Use

Editor THE AUTOMOBILE:—Would you please write and let me know what is the best oil to use in cold weather in the Continental motor. It does not seem to have the full strength after running for a half day. Would you blame it on the upper gasoline tank? It runs fine for a half day and then loses its power.

Philadelphia, Pa. WALTER SCHOEN.

—Use a light medium cylinder oil and keep the front of the radiator covered. The motor cannot work efficiently if it is cooled to too great an extent. The cooling system is designed to take care of the car on warm summer days. When the cold winds strike the radiator, they cool the water to such an extent that the motor runs much cooler. The heat which should be turned into power is allowed to escape through the radiator. It may seem strange that power losses should occur from such a cause, but it is nevertheless strictly true. The radiator area necessary on a cold winter day will probably be one-half that required in warmer weather.

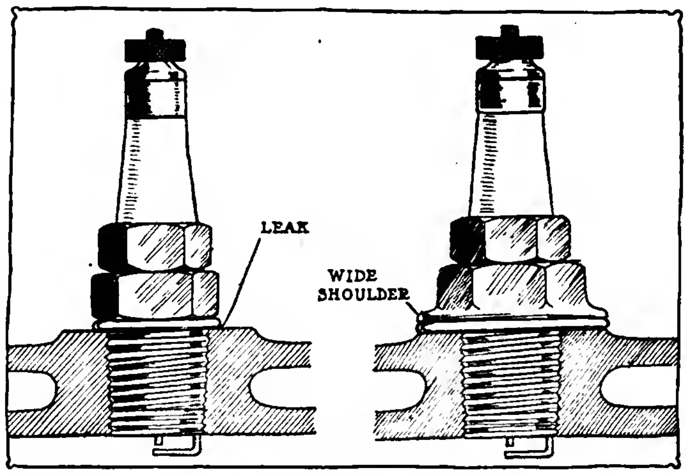

Fig. 6—How leaks may occur around narrow-shouldered plugs

European Patents

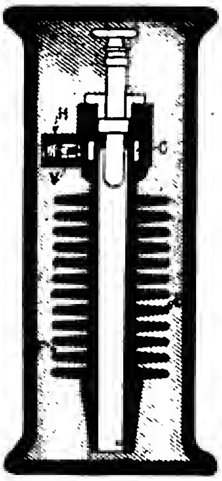

Fig. 1—Harpst plug and intake valve

INTERESTING inventions of various natures have been granted European patents during the last few months, and among these the number of engine designs embodying noteworthy ideas is striking. The invention along this line has concentrated largely as before in the production of silent motors, and, while the means for obtaining silence are in many cases akin to the principles involved in present designs, some meritorious improvements have been made, which bid fair to increase silence of operation and general efficiency of the mechanisms.

The prominence of sleeve valves is shown by the designs illustrated in Figs. 2 and 3. Fig. 2 illustrates a Renault design, covered by British patent No. 15,825. This patent involves the use of a reciprocating sleeve inside the cylinder and among the noteworthy features is the manner of obtaining a gas-tight joint between the valve, the cylinder and the dead space in the head. The sleeve-valve S which fits into the engine cylinder is shaped at its upper end with a flange seating on the beveled face H of the cylinder head. The sleeve valve is formed with horizontal ports operating in the conventional manner. The valve itself is actuated by the reciprocation of a walking beam one end of which is pivoted at P to the crankcase, while the other end is lifted periodically by the eccentric portion of the cam C. The follower always remains in contact with the cam, due to the tension of a spring S2.

Fig. 3 shows the engine design of Johnson, Hurley and Martin, covered by patent No. 15,298. The sleeve idea has been combined with that of the piston valve by fitting the sleeve to the periphery of the working face of the piston P1. This has been done to fill the requirements of the two-cycle engine here shown. The mixture compressed in the crankcase travels thence through a passage to the inlet port I which opens into the combustion chamber when the port P1 on the sleeve extension of the piston registers with it. Likewise, port P in the piston is provided to register with the exhaust port E in the engine cylinder.

Another Renault design is shown in Fig. 10, illustrating the subject matter of patent No. 15,907. The principal difference between this design and that shown in Fig. 2 is that the valve seats against a vertically inclined face formed on the cylinder head. The valve is shown at S and its seat at S1. This provides possibility of scavenging the combustion chamber almost perfectly, by placing the exhaust port E of the cylinder at the level shown in Fig. 10. The exhaust port in the sleeve is formed in its top section, and to provide perfect seating of the valve S, it is formed with a shoulder S2 subject to the pressure in the cylinder whereby it is held against the wall of the latter. Fresh gas is admitted through a pocket valve in the center of the head.

A rotary valve described in the British patent No. 14,944 is shown in Fig. 11. This valve design is the invention of G. Fornaca, of Turin, Italy. The rotary valve R is made with closed ends and its interior is kept in communication with the combustion chamber to a central port C, or through a pair of ports P and P1 which are formed near the valve ends. The valve is supported by a spindle S carried on bearings in partitions Q between adjacent cylinders. The valves serving various cylinders are not in communication but are carried on the same spindle. The explosion pressure holds the valve tightly against its casing.

A peculiar valve idea is shown in Fig. 6 which illustrates the Behrend patent No. 11,643. The valve V is held in position in the horizontal face of the piston which is equipped with such extensions that an upper and a lower seat for respective faces on the valve V are provided. The valve is weighted and if lifted off the seat S provides a passage between the crank or compression chamber and the combustion chamber. Operation of the valve is by the combined effects of the pressure in the crankcase and the cylinder, and the momentum of the valve itself.

Fig. 17 shows the engine described in Harveng's patent No. 13,565. This patent provides an annular reservoir around the inner port and close to the charging pump. The reservoir R is divided by a horizontal plate and is charged with air from the pump space P. Part of the charge enters the cylinder through the valve V, passing into C, while the rest of the charge passes through P1 to the chamber C1. The distribution of the charge in the cylinder is controlled by a sleeve formed as a vertical extension on the face of the piston. The mixture enters the cylinder after having been compressed in the crankcase, and after the combustion chamber has been scavenged by air entering through P2. The mixture is formed in the chamber C whence it is sprayed through jets J.

The two-cycle engine design shown in Fig. 9 includes the use of a rotary valve and a system of passages for conveying the gases to the cylinder and out of the same. In the case of fresh gases the mixture is drawn into the front end of the cylinder C at the end of each upstroke. It enters through a passage P in the piston through inlets passages I and I1 and a pipe P1 in which a rotary valve V is formed. This valve pro-

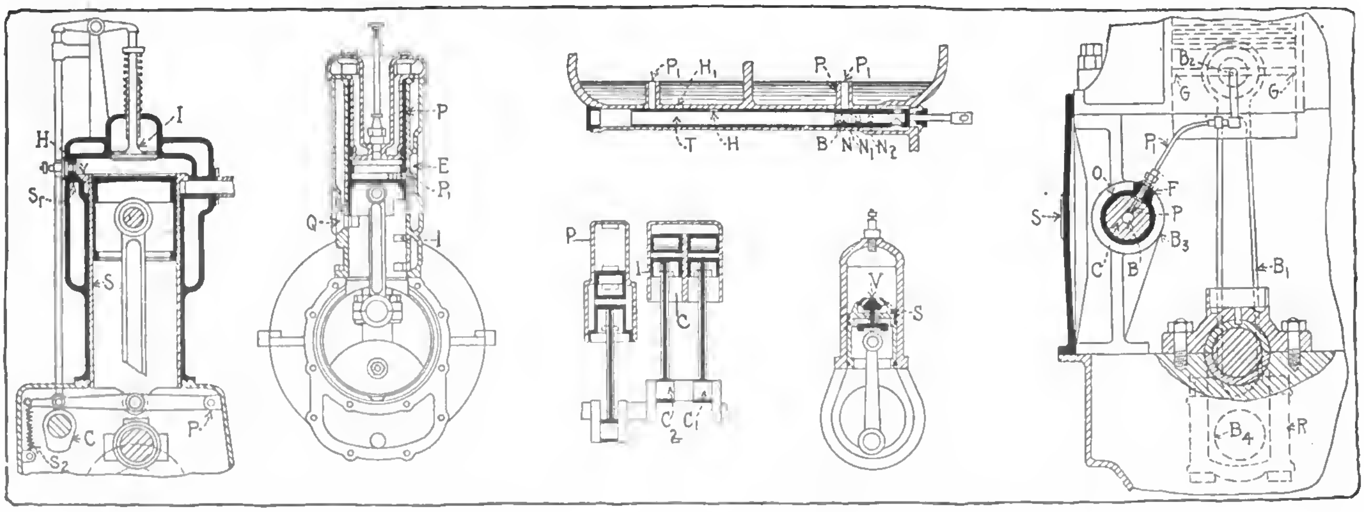

Fig. 2—Renault sleeve-valve motor. Fig. 3—Johnson two-cycle sleeve motor. Fig. 4—Peugeot lubricating system. Fig. 5—Albion twin-cylinder engine. Fig. 6—Behrend piston-carried valve scheme. Fig. 7—Russett lubrication

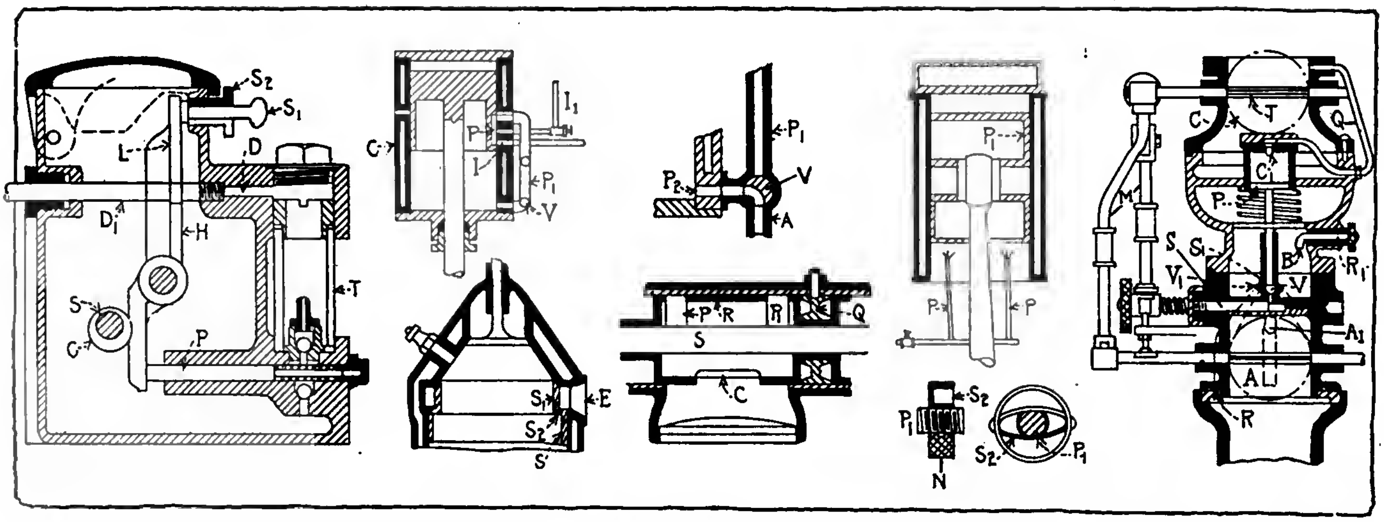

Fig. 8—Morris & Bunch oiling system. Fig. 9—Two-cycle engine va.ve. Fig. 10—Renault sleeve-valve improvement. Fig. 11—Fornaca rotary valve. Fig. 12—Daimler-Diesel motor improvement. Fig. 13—Weiss carbureter

vides a communication through pipes P1 and P2 when suitably positioned and also makes possible the admission of compressed air for starting the engine.

The German Daimler Company is interested in the Diesel principle, as is evidenced by the design shown in Fig. 12, which illustrates the British patent No. 14,598. In this patent the surplus of the compressed air which is used for injecting liquid fuel into the cylinders is utilized for cooling the piston P1 instead of blowing to waste, the air issuing from pipes P.

British patent No. 13,915 describes a two-cycle design patented by the Albion Motor Car Company. The idea which has been put into practice in this design is the use of one combustion chamber in common by two cylinders, the pistons of which are formed independent of one another but work on the throws C1 and C2 a common crank pin. The charge enters the combustion chamber of the double cylinder C through the inlet port I, Fig. 5, after having been compressed by the pump P which is accurated by a plunger set at an angle of 180 degrees to the connecting rods of the engine. No mention is made of special valves or valve gears in this patent.

Fig. 4 illustrates a patent taken out by the Peugeot company on a system of engine lubrication; the number of the patent is 12,487. The patent refers to a device for draining the oil from the crankcase either entirely or to the level of an overflow pipe. This object is realized by the use of the horizontal tube T sliding in another tube O, which is formed at the bottom of the crankcase. The tube B is formed with holes H registering either with holes H1 in the crankcase casting or with overflow pipes P which divides the crankcase into compartments, being formed on partitions P1. In the position shown in Fig. 4 H1 and P are shut and the oil flows through T to a chamber C provided with a stopper conduit whence the oil may be drained. The tube T is actuated by a lever and is prevented from rotation, being locked in any one of its three positions by a spring-pressed ball B which engages the notches N, N1 and N2.

Another patent referring to lubrication is shown in Fig. 8, being No. 13,382 granted to Morris & Bunch. This force-feed lubricator is composed of a number of pumps P formed in an oil reservoir, which force oil through sight-tubes T to delivery passages D. Tubes T contain water. Delivery pipes D1 pass through the reservoir emerging at the opposite side. The pumps are actuated by levers H driven by cams C on a shaft S. A variable stroke is provided by stops S1 adjustable by sleeves S2 which engage the extensions of levers L; the latter are hooked at H so that they may be placed over the delivery pipes D1.

In Fig. 7 the Russett system of crankshaft lubrication is shown, being the subject matter of patent No. 12,874. The oil is supplied to the various bearings by way of passages communicating with a bore in a rotating shaft other than a crankshaft; the camshaft may be used for this purpose. This is the case in the design shown in Fig. 7, camshaft C having a central bore B and a radial passage P communicating with a feed pipe P1 through which the oil is forced to the bearings. A flat F connects the bore B and the passage P1. Oils flows through O in the bearing B3 to an oil-box on the crankshaft bearing B1 as well as through a pipe P1 to an annular groove G in the cylinder wall, whereby the piston is lubricated. This groove communicates with the bore B2 in the gudgeon pin. From other orifices the oil is sprayed to a sight window S and into a cup formed on a connecting rod R, which communicates with a bearing B4.

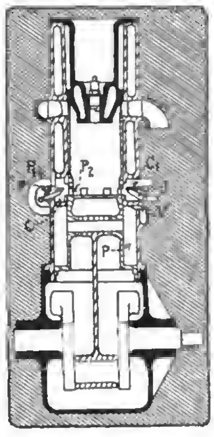

Fig. 17—Harveng engine

The patents referring to carburetion are likewise numerous. Fig. 13 shows a carbureter, described in patent No. 15,419, in which the inlet ports of fuel and of air are so connected as to work simultaneously. The primary air valve A, the butterfly T and the fuel valve spindle S are connected by the mechanism M. When the butterfly T is closed there is an annular space between it and the casing C. The passage of fuel is regulated by a valve V seating at V1 and connected through a piston P which is actuated by the engine suction. The suction is transmitted from the space above the butterfly through a pipe Q in which a check valve C1 is in place, which protects the valve V against backfiring. Shots S1 and V1 are provided to form fuel jets which carburet the air emerging from nozzles A1. The supply of air to the latter is regulated

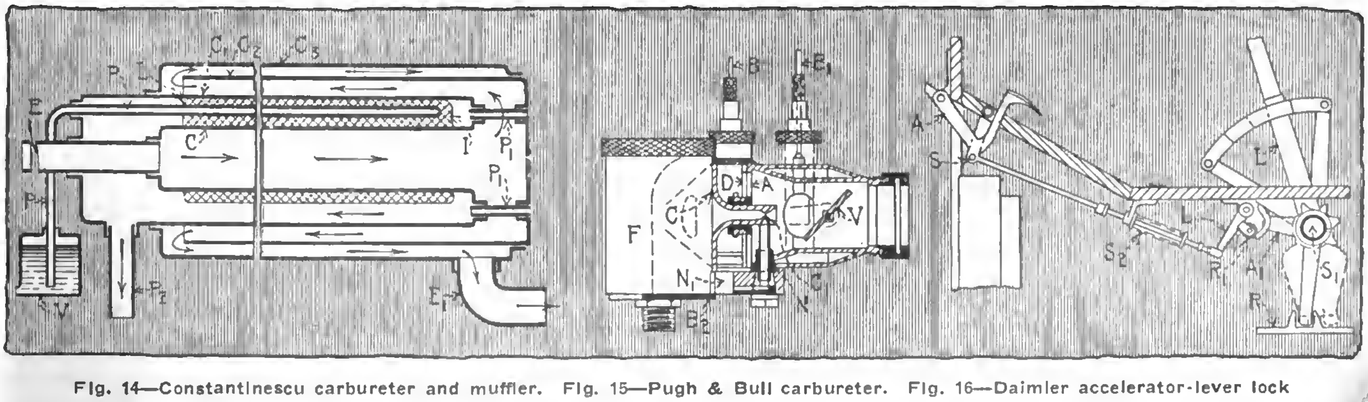

Fig. 14—Constantinescu carbureter and muffler. Fig. 15—Pugh & Bull carbureter. Fig. 16—Daimler accelerator-lever lock

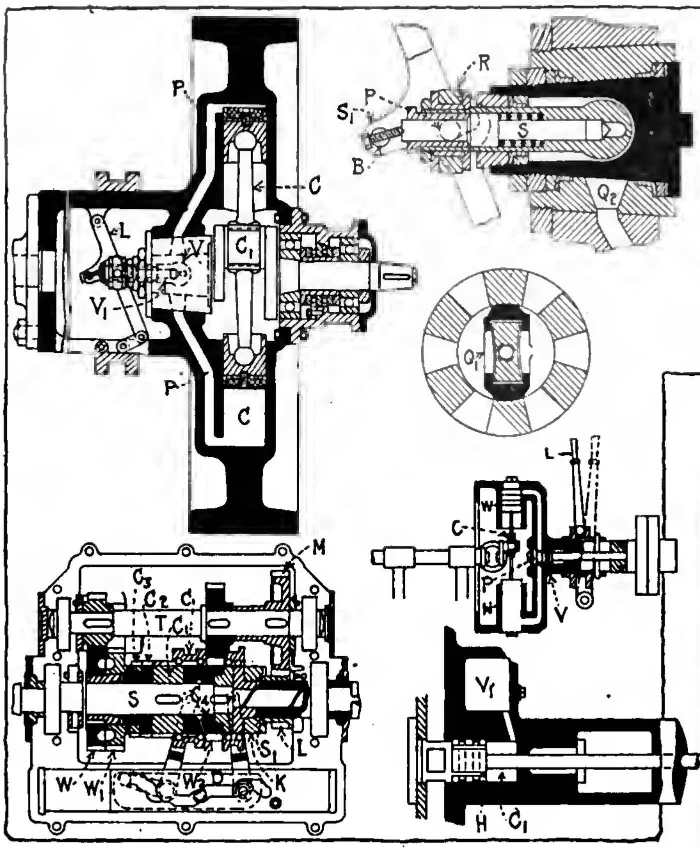

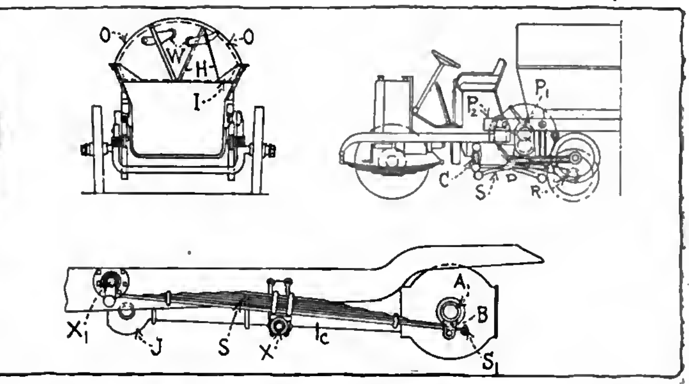

Fig. 18—Stokes hydraulic clutch. Fig. 19—Bond gearset. Fig. 20—Jones hydraulic clutch. Fig. 21—Fouchee refuse cart. Fig. 22—Rolls-Royce rear axle unit

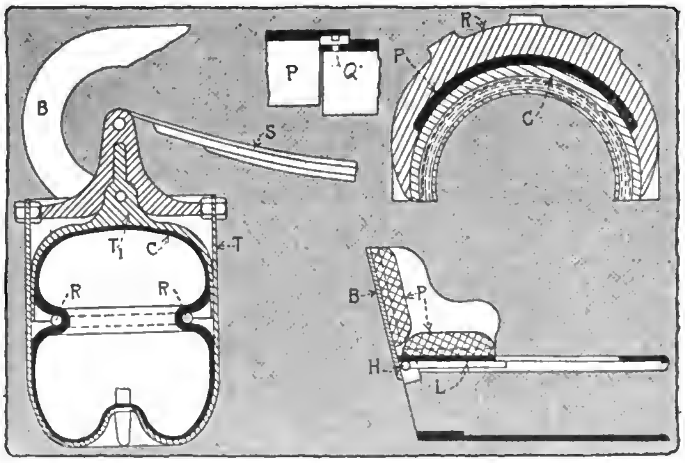

Fig. 23—Spyker pneumatic shackle. Fig. 24—Harris tire reinforced by metal plates. Fig. 25—Radford automobile seat

by air valve A. Priming is effected by turning the nut formed on the end of the rod R_1, whereby a spring-pressed plate which holds V to its seat is raised.

The carbureter shown in Fig. 15 is the subject matter of British patent No. 14,805. The nozzle end extends into a contracted portion C_1 of the cone C through which air is drawn into a chamber formed between a flow chamber F and the enclosing walls of the carbureter casing. This air serves only for spraying of the fuel whereas the air used for combustion enters through openings O; the latter is controlled by a ported diaphragm D actuated by a Bowden mechanism B. A throttle valve V and Bowden mechanism B_1 control the admission of mixture to the motor. The flow of fuel is regulated by a float positioned in a float-chamber F which is carried on a slotted bracket B_2 and is fitted with a block N_1 supporting the nozzle N.

The Daimler Motoren Gesellschaft, in patent No. 12,645, describes a device for locking the accclerator lever automatically, when certain higher speeds are engaged. This is accomplished by the arrangement of the accelerator lever A, Fig. 16, and the stop S which latter comes in operation only when the speed-changing lever L actually puts the gears mentioned in operating position. When L is moved along the spindle to select the operating rod R for the third or fourth speed, arm A_1 comes into alignment with roller R_1; the latter is carried by a lever L_1 connected to the stop S. The end of A_1 forces S into its operative position when the lever L is turned about its axis S_1 to engage either of the speeds above mentioned. Ordinarily the stop is held inoperatively by a spring S_2.

A carbureter which at the same time acts as a muffler is the design of G Constantinescu, described in patent No. 12,759. The construction involves four concentric cylinders C, C_1, C_2 and C_3, which serve as a passage for the hot exhaust gases entering at E and leaving at E_1, the flow of these gases being indicated by arrows. The fuel is carried in a vessel V from which a pipe P leads to a higher portion contained within the exhaust heated carbureter, being supplied to a layer I of incombustible, heat-conducting material. There it meets air entering through P_1 and after having been mixed with it leaves through P_2. On its way to the engine the mixture may be diluted with further air.

Combining the office of a spark-plug with that of an intake valve the subject matter of Fig. 1 deserves special mention. The invention is that of F. E. Harpst and is described in the British patent No. 11,811. The spark-plug proper is shaped with a shell ending in a conical extension lifting into the cylinder head. This shell is formed with cooling ribs or fins R and inside of the shell a chamber C is provided which surrounds the insulated sparking electrode. This chamber has a lateral pipe extension P which serves as an intake opening and communicates with the cylinder space through the central ball of the plug. Fitted into this pipe is a check-valve opening into the chamber C through which fresh gases are omitted when the piston is on its suction stroke and which is closed by the compression in the cylinder as the piston returns on its upward travel. The incoming charge passes over the inner walls of the shell and cools it, thereby assisting the action of the fins R.

A hydraulic clutch idea which is rather interesting is illustrated in Fig. 18. The clutch is the invention of R. O. Stokes, and is described in detail in patent No. 11,561. Fig. 18 shows the details of construction including the cylinders C which are formed in the flywheel and through which the fluid is pumped, which is circulated to form a connecting unit between power plant and driving set. A system of ports and valves is used to control the flow of the fluid throughout the system; the ports P lead to the central valve chamber formed in alignment with the center around which the crank C_1 revolves, which chamber is divided by a plate secured to the crank. In this plate works the outer valve member V which controls the flow of fluid through the port Q_1. The inner valve member V_1 controls the passage Q_2 through the member V. It is operated by a lever L and the spring S which tends to hold it in a certain normal position. A pin P connects the lever to the member V, this pin being carried by a trunnion ring R. The pin works in a slot affording sufficient lost motion to permit of independent movement of the inner valve member V_1.

Fig. 20 shows another hydraulic clutch construction invented by T. G. Jones and described in patent No. 12,707. Attached to the shaft of the motor is a crank on which bear the oppositely mounted connecting rods of two pistons adapted to work in cylinders W. The interiors of the latter communicate through a passage P, the cross section of which is variable of a valve V operable by a lever L. The casting of which the two cylinders are parts is mounted on the driven shaft which actuates the differential. The method in which this mechanism operates is as follows: If the valve is in such a position that it closes the passage entirely, the pistons are locked in their relative positions and the driven shaft on which the cylinders are mounted is in direct gear with the driving shaft. If the valve is fully open the crank C revolves around the crankshaft and actuates the two pump cylinders W passing the actuating fluid alternately from one to the other so that the driven member which is mounted on a driven shaft remains stationary. Partial opening of the valve gives a variety of speeds.

Fig. 19 shows a transmission idea described in patent No. 15,911 being the invention of E. S. Bond. A clutch member C carries several circles of balls and is adapted to engage a tooth wheel. These balls may be brought into engagement with parallel grooves in cylinders C1, C2, C3 and C4 surrounding the driven shaft S of the gearset. C1 is secured to S while the other members are fastened to the bosses of gear wheels W, W1 and W2, respectively. Positive engagement between the member C1 and any of the other three may be obtained.

In Fig. 21 a refuse cart construction is illustrated which is described in patent No. 14,117. The airtight cart is coupled to the tractor by a set of double pins. The rear wheels are supported on stud axles which are carried by the arms A pivoted at P. Springs S are attached below the arms A and at their other ends by screw connectors C. To connect the tractor to a two-wheeled cart the latter is brought close to it and coupled by pins P1 or P 2, after which connectors C are unscrewed until the second set of pins may be put in place, while further unlifting raises the wheels of the cart off the ground. Charging openings O are provided in the top of the cart and a hopper is formed by an inclined plate I and a hinged panel H which is normally kept closed by a counterweight W.

An interesting form of spring suspension is shown in Fig. 22. The live axle casing A is rigidly connected to a casing C pivoted to the chassis frame on a joint J and acting as a radius rod. The side spring S is pivoted at X and X1, having its rear end sliding in a bracket B on the casing A. The stop S1 keeps the spring end from leaving the chassis frame in case of rupture of the casing C. Patent No. 13,516 describes this invention in detail, the patentees being F. H. Royce and Rolls-Royce Ltd.

Another invention referring to the subject of suspension is described in patent No. 14,757 of J. Spyker. The subject matter is a compensating shackle, Fig. 23, consisting in principle of a pneumatic bag inclosed in a casing which consists of two telescoping members T and T1, one of which is fixed to the master leaf of the spring S and the other to the end of the spring reach B. The pneumatic casing C1 is held together in the middle by a ring R which may be supplanted by an annular projection of the internal diameter of the casing part T.

Among the many interesting inventions pertaining to tire design and manufacture is the tire shown in Fig. 24. The outer casing is reinforced by the insertion of metal plates extending transversely through it, being laid over the fabric and under the rubber tread. Individual metal plates P thus form a ring over the tire fabric, being attached to one another by means of studs and holes shown at Q. This puncture-proof tire is the invention of A. R. Harris and the patent is No. 15,353.

Improved automobile seats are the subject matter of patent No. 15,735, granted to W. Radford. The seat described in this patent is really a rumble seat which is formed by the cover of a box carried behind the runabout seats. The member B, Fig. 25, is hinged at H and forms the back of the seat, a loose member L forming the seat proper. These two parts are padded at P and each is formed with an arm rest A. Fastening members engage the rear portion of B when the seat is not in use, whereas otherwise the front end of L is held by them.

Fig. 26 shows a constructional detail of the tire described in patent No. 11,666, the invention being that of T. Gare. The rubber body R of the tire is vulcanized to the metal base M, a layer of vulcanite being in place between R and M. To increase the adhesion between R and M the vulcanite is formed with a serrated or similarly irregular surface S.

British patent No. 15,019 deals with a spring tire construction shown in Fig. 27. The tread T is secured by latteral bands B to outer rims O which are in turn connected to the inner rim I fitting around the wheel felloe. A web W projects from the rim I into the space formed between tire tread and bands B, and between this web and the bands a series of helical springs H are in place which tend to hold the bands in properly spaced relation from the web and are adapted to absorb shocks, etc., imparted to the tire rolling over the road. G. Racca and G. Dall'Oglio are the inventors of this tire.

M. Wolff, in patent No. 15,144, describes a detachable rim attachment shown in Fig. 28. Each rim is formed with a projecting flange F protecting securing bolts and similar member if a single rim is used on the wheel, while in case of dual rims the flanges serve as facing rims as in the illustration here shown. Interengaging lugs are arranged on the fixed and detachable rim members and, in the dual form of rim the valve stems V are arranged at the side of the felloe and not through the same as in ordinary practice.

A spring tire which offers possibilities is described in patent No. 15,319, having been granted to R. Rhone. It comprises a continuous tire T having beaded edges, with ends joined by a metal shoe M, Fig. 29. The latter is guided by a side-plate P supported by helical springs which are contained in recesses formed by transverse webs W. A plate Q forms a bearing between each spring and the tire, and a rod R on each plate Q engages notches in the helical spring above which it is in place.

A tire valve cover, Fig. 30, is the subject matter of patent No. 12,943, the inventor being W. G. Nelson. The covers for the security bolt and valve stems comprise a hollow, close-ended nut N which carries a rotatable sleeve S fitted with a rubber washer W. Movement of the sleeve on the nut is prevented by a collar on the nut which engages ribs and grooves G on sleeve and nut. The formation of the part P is such as to permit of easy application of a spanner.

British patent No. 15,415 deals with the peculiar tire design shown in Fig. 31. The casing is formed with a centrally and internally extending tongue T which fits between the sides of a groove G.

Engine-worked tire inflation is the object of the invention illustrated in Fig. 32 which is described in patent No. 12,085. The Beorchia scheme provides a friction wheel W actuated by the flywheel and suspended on an arm R. The shaft on which the wheel is mounted has an eccentric carrying a connecting rod bearing, and the connecting rod is connected by a joint J to the plunger which carries the pump piston.

Electric Cranking and Lighting

Part II

Taking Up the Electric Systems Now on the Market. In Studying These Systems the Physical Layout Adopted by Each Maker Should Be Noted Along with Details of Design

Subject Digest

¶ Makers of Electric cranking and lighting systems have had a sudden demand thrust upon them. The big question of the New York shows, asked by every intending purchaser of a car priced at more than $1,000 was: "Have you an electric starter?" This demand has caused a flood of designs.

¶ The youth of the electric cranking and lighting industry is shown by the great number of varying designs placed on the market. No two are alike in even the essential details, although making use of the same principles.

¶ Two-unit and three-unit systems are leading the way, although the single-unit system with the ignition and lighting generator and the cranking motor all in one casing are coming into prominence along with the increase in 6-volt systems.

¶ Most of the starters now on the market have been fitted to the car after the car itself was designed. They have been put on as an afterthought. The results in a number of cases, as far as appearance goes, show this. Six months later, the cranking motors will not be as clumsily mounted as many of them are now.

LAST week THE AUTOMOBILE gave in as simple a form as possible the main features of an electric system on an automobile. It was pointed out that there must be three main units. A battery, a generator and a cranking motor to make up a complete ignition, lighting and starting system. These units must possess certain relations to one another and must perform certain functions. The requirements of the units and their relations were fully discussed in that issue and it remains now to touch on the systems which are at present in use.

The youth of the manufacture of electric cranking instruments cannot be better shown than by the great variety of types now on the market, although the same basic principles can be seen in each application. Since this is the first year that the electric cranking motor can be said to have come into its own, it is manifestly impossible to state that there is any trend in the manufacture of these instruments. The equal division between the 6, 12 and 24-volt systems show that the opinion of the designing engineers is at great variance on this subject.

An equal division also may be noted between those who are using the motor and the generator in two separate and distinct units and those who are putting them together in one housing. The advantages of simplicity are argued by both sides as their reason for either making the system in a single or double unit.

One of the noticeable points in the installation of the electric cranking systems is the clumsiness with which they are mounted on the chassis. The reason for it is apparent after a moment's consideration. The starter is the result of a sudden demand and the result has been that they have been installed after the design of the engine and chassis was complete. They have simply been added. The result of this has been in many cases a bad engineering job. The drive has been defective, the appearance anything but satisfying and the result on the whole bad. Even on these installations, however, credit must be given for the ingenuity displayed in applying cranking motors to engines and chassis which were designed and built without the slightest idea of any such installation. There are many which are so designed that they can be applied even after the car is in use.

Gray & Davis—Three-Unit System

The Gray & Davis electric lighting and cranking system belongs to the three-unit class. Two units are furnished by the company, namely, an electric generator and a cranking motor. The third, or ignition unit, is optional with the purchaser and is not supplied by this company.

Both the electric generator and the motor of this system operate at 6 volts. A 6-volt battery is therefore used with this system, its capacity varying with the size of the motor which has to be started and the number of lamps used.

The generator is driven either through gears or by means of a silent chain. The speed of the generator is regulated by means of a centrifugal governor. This governor permits the generator to be driven positively up to 750 revolutions per minute in the case of one size of generator and 1,000 revolutions per minute in the case of another. Above these definite speeds the governor causes the driving clutch to slip, thus maintaining the armature speed very nearly constant.

These critical speeds are reached at a low car speed, so that the generator gives its full output when the car is traveling from 10 to 15 miles per hour, this variation being determined by the gear ratio and size of tires on any machine. The generators are geared 2:1 or 1.5:1 depending on the size used. They are driven either by silent chains or gears.

The regulation of the amperes output is accomplished in two ways on the Gray & Davis generator. The machine is compound-wound, namely, with a shunt field, SHF, and a series field, SEF, Fig. 1. Unlike most compound-wound machines used for electric lighting, the two field windings assist one another instead of oppose. For this reason this is called by the electrical engineer a cumulative compound instead of differential compound machine.

The regulation of maximum output is effected by the centrifugal governor, which keeps the speed of the machine constant. For that reason this may be placed in the class of mechanically regulated machines.

The purpose of the additional field, SEF, is to increase the output of the generator as the lights are turned on, without increasing the speed of the generator. For example, with all lights out, the generator will deliver about 6 amperes, while with all the lights burning it will develop 12 amperes. In between these two points it will deliver additional amperes in proportion to the candlepower of the lamps burning, that is, with half the total candlepower, 9 instead of 12 amperes will be the output.

An over-running clutch is always applied to the train of gears in the Gray & Davis system in order to prevent the gasoline motor from driving the cranking motor when the former starts up.

A starter switch connects the battery with the motor when cranking. This circuit is separate from the lighting and is direct from the battery to the motor.

A circuit independent from the lighting is used for the starter. Wires connect direct from battery to motor and are of No. 0 size in most installations, although in some No. 000 has been used to insure maximum efficiency. The starting switch, SS, is placed in this line. This switch is interconnected with the cranking gear train so that when the starting gear is shifted into mesh with the flywheel gear the current will be turned on.

The starting switch has two points; the first permits only a small current to flow to the motor, while the second allows the full battery current to rush through the motor. The first condition is obtained by imposing resistance in the line. Its purpose is to permit easy meshing of the gears without throwing on full power before the gears are meshed their full width. This is the usual practice with all types of flywheel geared starter switches.

This is the only machine with mechanical regulation which provides for an additional regulation in proportion to the output of the generator, Figs. 2 and 3.

The two generators which Gray & Davis make both have the distance from the base to the center of the armature the same, namely, 2.68 inches. In over-all length one of the machines is 12.11 inches long, the other 11.34 inches. In over-all width they are both 5.5 inches. The larger one weighs 32 pounds and the smaller one 25 pounds.

For cranking, two electric motors are provided by Gray & Davis. One weighing 38 pounds and capable of cranking motors up to 36 horsepower and the other weighing 66 pounds and suitable for 75-horsepower motors. In both cases these motors are designed for a working speed of 1,500 revolutions per minute using 6-volt current. Both motors are cylindrical, one 8 inches in diameter, the other 6.63 inches.

The gear ratio used between the motor and the crankshaft naturally varies with the size of the motor to be cranked. It varies from fifteen to one in the case of a small motor to twenty to one in the case of a large motor. Assuming a cranking motor speed of 1,500 revolutions per minute the gasoline motor will turn over at the rate of 100 revolutions per minute with the first gear ratio and 75 revolutions per minute with the second ratio.

The current drawn in each case will vary with the size of the motor, the temperature conditions existing at the time of starting, the speed at which the motor is rotated and the condition of the battery. These are fundamental considerations and must be taken into account whenever comparing starters.

The Gray & Davis cranking motor takes current at the rate of 80 to 120 amperes under normal conditions. These are only relative values and not specific.

On account of the comparatively large reduction between the cranking motor and the crankshaft it is particularly convenient to apply the power from the Gray & Davis cranking motor through a train of reduction gears one of which meshes with a gear on the flywheel. The size of the flywheel makes it possible to get a large reduction very conveniently and for that reason is very popular with this type of starter. This system is applied in other ways with equal success, as, for example, through a worm and gear attached to the transmission gearcase.

Ward Leonard—Three-Unit System

Another 6-volt system of lighting and cranking is furnished by the Ward Leonard Electric Company. The system is placed in the three-unit subdivision as a separate motor and generator are used. The ignition system which may be used is optional with the purchaser. Either magneto or magneto ignition can be used.

The output of the generator depends upon the size of the battery to be charged. It is usually fixed at the charging rate recommended by the battery makers for initial charging. Inasmuch as the user drives his car only for short periods at a speed which would cause the generator to give its maximum output, it is claimed that it insures a full charge all the time. As the battery makers claim that overcharging is more desirable than undercharging it is evident this is erring on the safe side.

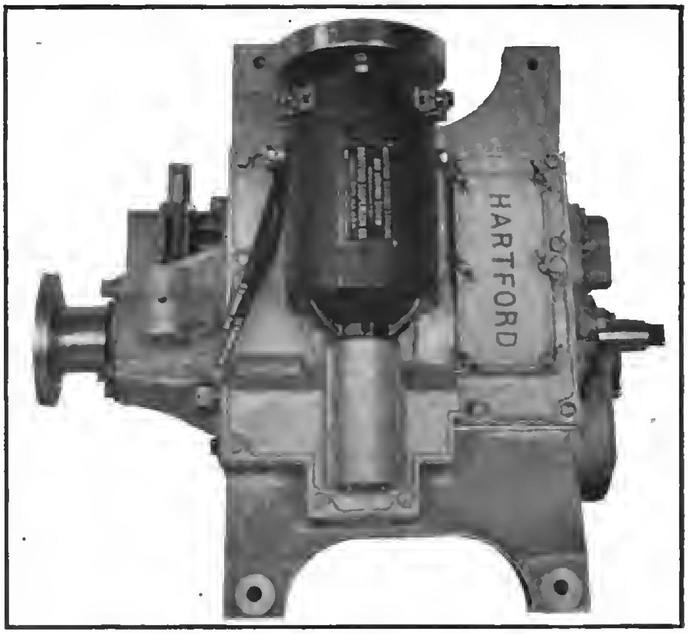

Fig. 4—Mounting the Hartford motor generator on gearset

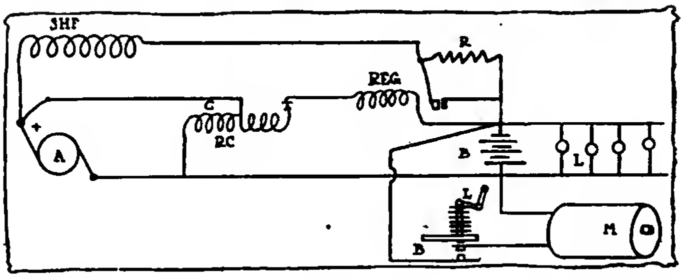

Fig. 5—Ward-Leonard wiring diagram for electric cranking system

The generator meets the maximum load from 300 to 350 revolutions per minute, depending on the gear ratio of the car upon which it is mounted. Above this speed it charges the battery. The generator may be driven at crankshaft speed or at one and one-half to one. The company also builds a lighting generator which operates at two to one. The weight of the generator is about 30 pounds.

The system consists of three units: a generator, motor and regulator. The regulating devices are contained in a small box which may be mounted either at some convenient place on the chassis or on top of the generator. The latter position greatly simplifies the wiring of the car.

The regulator contains two devices, a reverse current cut-out and the output regulator. The reverse current cut-out, RC, consists of two coils, the potential or voltage coil closing the relay and the current coil holding the relay closed until a reverse current opens it up. The regulator merely consists of a current coil in the main line. This inserts resistance in the field circuit when the output reaches a predetermined point. The controller is in constant vibration whenever the generator comes up to a speed where it delivers or exceeds the maximum output allowed. It will be seen from this that the entire control is accomplished by this regulator and that the generator is a simple shunt-wound machine.

The Ward Leonard cranking motor weighs about 38 pounds for a 45-horsepower motor and the company builds in addition a smaller cranking motor for engines of less than 25 horsepower. The characteristics of these motors differ somewhat from the general run of 6-volt apparatus in that they are designed for high speed. When under load they run at from 2,500 to 3,500 revolutions per minute. As a result the gear ratio necessary varies from thirty to one to forty to one.

The current required for continuous cranking varies from eighty to 100 amperes at 6 volts. This will crank a motor from sixty to 100 revolutions per minute depending upon its size. The most usual method of connecting the motor to the engine with this system is through the flywheel. On account of the large gear ratio necessary with this cranking motor it is almost necessary to include the flywheel in the gear train in order to reduce the size of the gears.

A special switch is also used for cranking. It consists of laminated copper strips about 1.25 inches wide and 5 inches long. They are fastened to a copper block forming one of the terminals of the switch at one end and are brought into contact with another block when it is desired to start the cranking motor. An eccentric is used to force the contacts together. There are two points on the switch, one for permitting the motor to turn over slowly to facilitate meshing the gears and, second, the running position.

Hartford—High Speed Motor

The Hartford electric system has three units, the motor, generator and magneto being separate and distinct units. The system is so arranged that the generator is controlled by a governor which operates at a car speed of 14 miles per hour and by a cutout which operates in the neighborhood of 6 miles an hour. The storage battery floats on the line. The generator is geared constantly to the transmission gears or timing gears at the option of the purchaser.

Taking up the units independently, it may be stated that the generator is of the permanent magnet type with auxiliary electromagnetic fields, the latter being wound around the pole shoe extension. The pole shoes of malleable iron are fitted to a cylindrical housing provided with threaded ends to which are attached the end covers. The covers have knurled edges, making it easy to remove the parts desired. The armature is drum-wound and has the wires insulated by a baked-on substance which renders them impervious to moisture. The commutator segments are separated by insulating material wound directly on the chrome-nickel steel armature shaft. The armature shaft is carried on ball bearings designed to take both radial and thrust loads.

In order to protect the battery from the high voltages which would be created if the generator were driven at excessive speeds a centrifugal governor of the friction type is employed and comes into operation at 14 miles an hour car speed.

The brushes employed to take the current from the commutator of the generator are of the carbo-metallic type. They may be reached by lifting a spring-retained cover mounted on the end casing. The brushes and holder may be removed as a unit. In

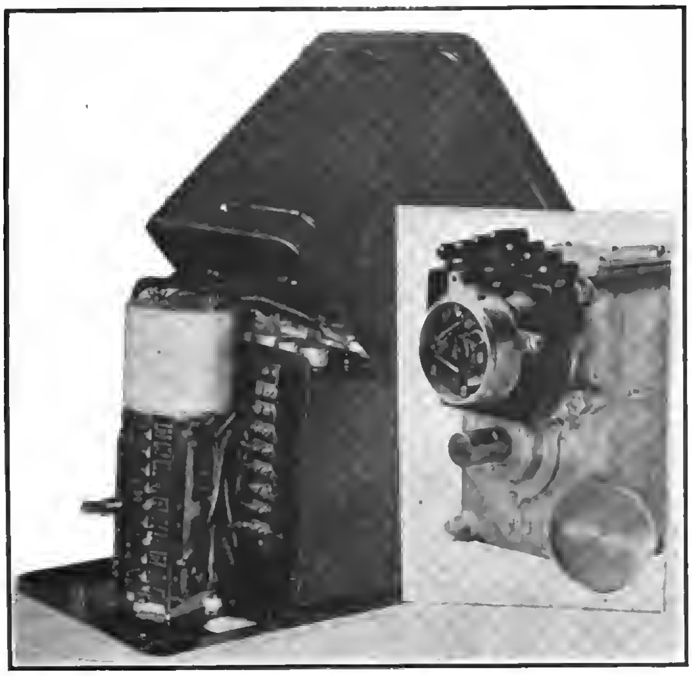

Fig. 6—View of Electro generator, showing interior and mounting of distributor on casing

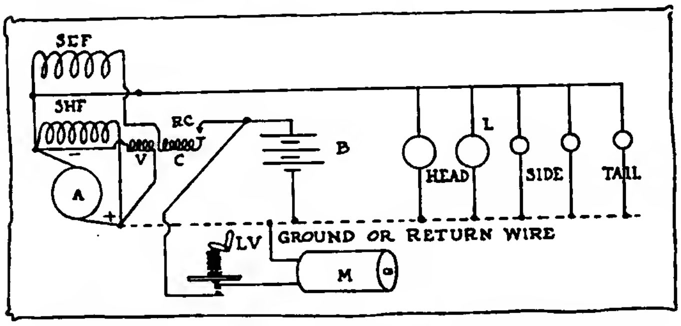

Fig. 7—Wiring diagram of Westinghouse six-volt system, showing grounded return wire

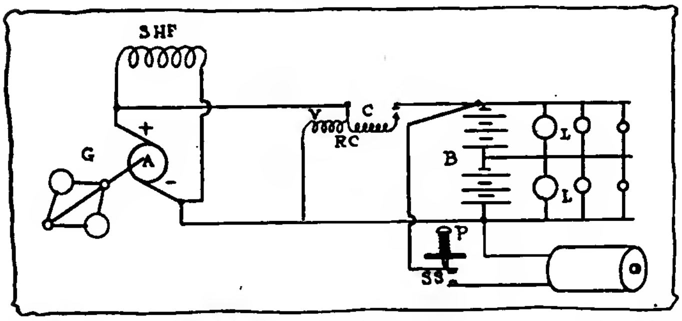

Fig. 8—Wiring diagram of the Hartford system for lighting and cranking

systems where the battery is floated on the line it is necessary that the generator be cut out when the voltage developed falls below that of the battery or else the battery will be discharged through the commutator. In the Hartford system a magnetic reverse current cut-out, R C, is used. The generator is cut in when the automobile is traveling at 8 miles an hour and is not cut out until the speed of the car falls to 6 miles an hour. It is entirely automatic in its action. At a car speed of 8 miles an hour the generator is developing approximately 7 amperes. As the car is speeded up the rise in the amperage is gradual until a speed of 15 miles an hour is obtained, at which point a little over 11 amperes is developed. From this point the curve declines to 8.5 amperes, which is held at 25 miles an hour and over. The

voltage curve starts at 13 at a car speed of 7 miles an hour and rises gradually to a maximum of 14 volts. The generator is driven from the crankshaft, on the recommendation of the manufacturers, by silent chain at the ratio of three to one, although gear drive may be employed if desired. The battery is of 12-volt, 60-ampere-hour capacity. The headlights are connected to one-half the battery and the dash side of the tail lamps to the other half, hence all lights operate at 6 volts.

The electric cranking motor is of somewhat unusual type in that it is designed to operate at about 7,000 revolutions a minute. The gear reduction between the motor and the crankshaft of the gasoline engine varying from 100 to 1 to 125 to 1, the reduction being obtained by a combination worm and spur gear having an efficiency of 85 per cent. In other words, the crankshaft is revolved at a rate of from forty to seventy turns a minute, depending on the engine size, compression, stiffness, temperature and other conditions. To further describe the motor, it may be said it is of cylindrical shape, 7.5 inches long and 4.5 inches in diameter. Its weight, including gears, etc., is 35 pounds, and without the gears, 20 pounds. The extension of the armature shaft is provided with a worm which meshes with a large gear giving a reduction of twenty-five to one. A further reduction of five to one is secured by spur gears. The efficiency of the small motor is secured by the use of a small flywheel weighing 4.5 pounds, which, turning over at 7,000 revolutions per minute stores up considerable kinetic energy between the times when the motor is acting against the compression of the gas engine, thus enabling it to carry its load at a very nearly constant speed. The gears between the motor and the engine crankshaft are always in mesh, but since the worm gear is not keyed to the shaft of the motor but is secured by a friction over running disk all danger of harm to the electric motor, should a backfire occur, is eliminated. The starter consumes on an average between 200 and 225 watts. The motor is series-wound, the torque increasing with the load.

U. S. L.—Flywheel Installation

The U. S. L. is a two-unit system. In installing this system the armature of the motor-generator supplants the flywheel and performs its functions as well as those of the electric lighting

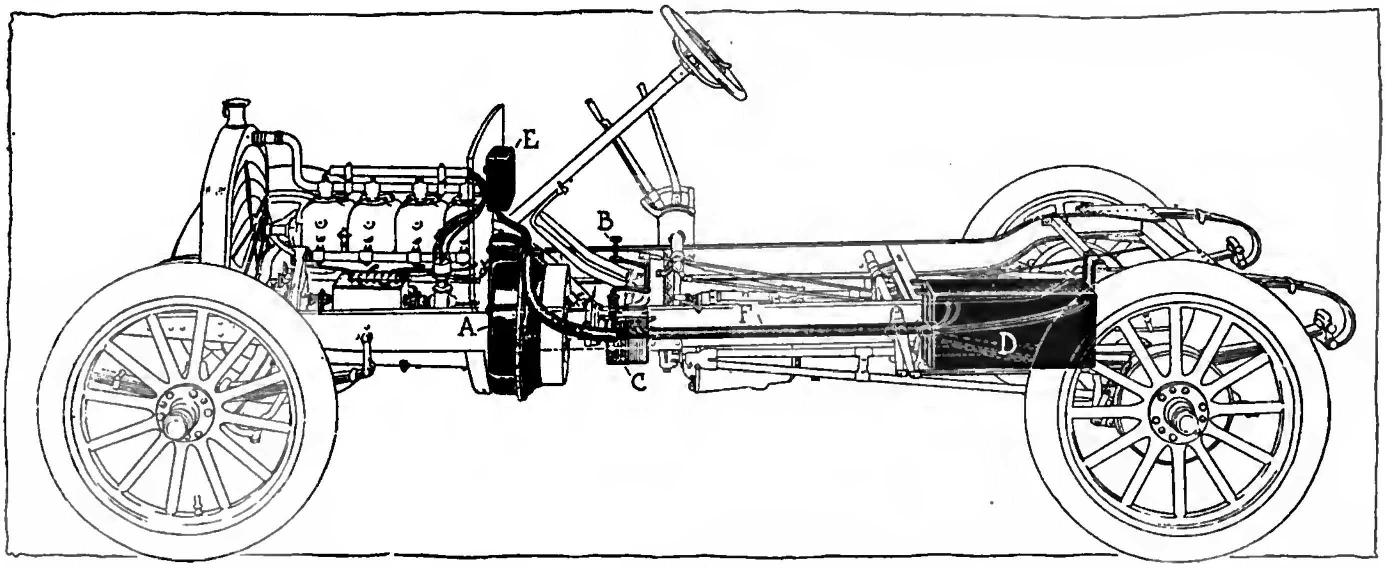

Fig. 9—Mounting of U.S.L. system on Rambler Car; A, motor-generator; B, starting pedal; C, switchbox; D, battery; E, regulator

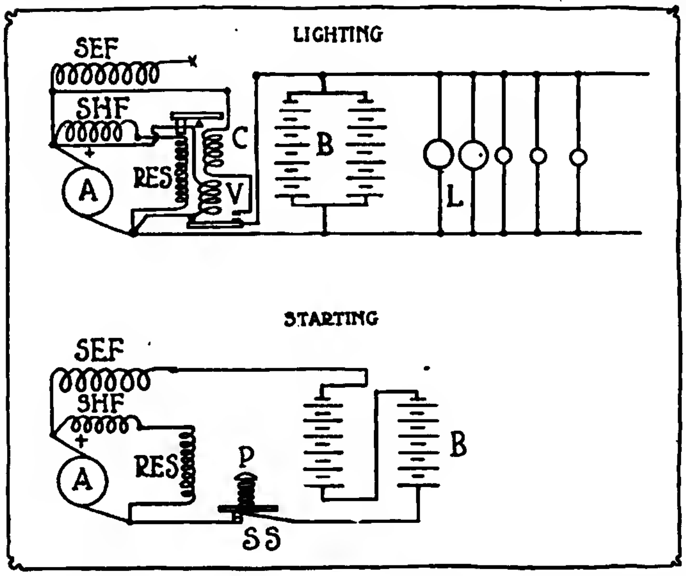

Fig. 10—Wiring diagrams of U.S.L. lighting and starting systems

and cranking systems. There are two independent windings on the field, one for the motor and one for the generator. The voltage of the motor is 24, while the charging voltage of the generator is 12.

The preferred disposition of the units is that shown in Fig. 9. As will be seen, the added weight will be only that of the battery, fields, switches and controller as the flywheel is removed and replaced by the armature of equal weight. When a foot switch is pressed the battery is connected to the motor and this turns over the gasoline engine at the rate of from 200 to 300 revolutions per minute. The speed at which the motor is turned over and the amperage drawn in turning it over are functions of the stiffness of the motor and its size, or, in other words, the amperage drawn by the same voltage rises in proportion to the resistance. The field is in series with the armature and is assisted by the shunt field, Fig. 10. With series motors the field excitation is greater as the motor speed falls and the torque of the motor increases. The amperage drawn by the motor in spinning the engine in the average case will jump to 150 and then will fall back to a running amperage of approximately 75.

As soon as the motor picks up to a speed giving 8 miles an hour, the motor generator becomes a shunt-wound generator and starts to charge the battery, restoring the current used at a 30-ampere rate. In order that the output of the generator shall be uniform a carbon pile regulator operated by a series coil C, is used. This keeps the output through the working range of from 600 to 1,200 revolutions per minute practically constant. At higher speeds than the latter the output drops off and thus a dangerous overcharge to the battery is prevented. In order that it will be impossible for the battery to discharge back through the motor generator at speeds below charging or while the car is standing at rest a reverse current cut-out opens the line between the battery and the motor generator.

On account of the small added weight, the motor generator parts in this system are made larger than if it were necessary to cut them down to the minimum. The commutator, for instance, is 10 inches across and the carbon brush contact is .75 square inch on the average installation. The storage battery used with the system has a capacity of 130 ampere-hours at 12 volts.

Westinghouse—Grounded Return Wires

The Westinghouse combined lighting, cranking and ignition system has two units. First, a cranking motor which may be located in the most convenient position, and, second, a generator which takes care of the lighting circuit and also of the ignition. The entire system is operated at 6 volts and is grounded at one point. This greatly reduces the wiring, and since every part of the system is at the same voltage permits of the use of single contact lamp sockets, etc.

The generator in the Westinghouse system takes care of ignition as well as lighting. It is of low speed, turning over at crankshaft speed on four-cylinder motors and at 1.5 crankshaft speed on sixes. It can be driven from the crankshaft or installed in any convenient place. There are no permanent magnets used in the generator, which is of the compound differential-wound type. The output of the generator is controlled electrically due to the compound winding. A reverse current cut-out is provided and is so adjusted that on the average four-cylinder car the battery circuit is cut in above 10 miles an hour and cut out below 7 miles an hour. This difference prevents the switch from cutting in and out continuously when the car is running at one particular speed. When the generator is connected to the battery by the automatic switch the current rises rapidly with the speed until a value of from 5 to 7 amperes is obtained if the lamps are not burning. Above this the output rises very gradually, the curve being nearly flat for all motor speeds so that the danger of an excessive charging rate in day touring is eliminated. This is accomplished by the reversed compound field winding on the generator.

When the lights are turned on the output of the generator increases proportionately. This is accomplished in the following manner: Assume that the load is 6 amperes, that the generator output is 3 amperes, then 3 amperes will be taken from the battery. The battery current must go through the series field SEF on its way to the lights, thus assisting instead of bucking the shunt field SHF.

Now assume the condition of 7 amperes output from the generator and a lamp load of 6 amperes. This leaves 1 ampere for charging. That 1 ampere goes to the battery through the series field SEF, and in the reverse direction which causes that field to oppose the shunt field instead of assisting it as in the above case. The figures are merely for explanation.

The preferred installation of the cranking motor is by gear to the flywheel or to the front end of the crankshaft. The reduction from the cranking motor to the engine varies from 10 to 1 up to 22 to 1. The amperage on the jump or when the starting switch is first thrown in is 200. The storage battery capacity is 100 ampere-hours. The starting motor is series wound and is made in three sizes of different torque rating to take care of gasoline motors of different ratings. The switch which operates the starting motor has two points. The first movement causes the electric motor to turn over very slowly to facilitate engagement of the gears, between the motor and the flywheel, and the second point causes the cranking motor to spin the engine.

Aplco—Two-Unit System

The Aplco is a two-unit system. The electric cranking motor and the generator are contained in one unit and the magneto forms the second unit. The make of the magneto is optional and is separate and distinct from the lighting and cranking systems. The system operates at about 6.5 volts as far as the lamps and generator are concerned. The cranking motor, however, operates at 24 volts except in the case of installation on the Interstate motor, where the cranking motor operates at 30 volts. The generator is the low-speed type working at crankshaft speed. The generator may be driven by chain, gears or by any other means compatible with the crankshaft speed at which it is designed to run.

The weight of the motor-generator is 70 pounds. The generator furnishes current for the lighting system, however, and therefore its weight is less than the weight of two units, which it replaces.

The regulation of the current from the generator at high speeds is governed inherently by the compound differential winding on the motor-generator. **Besides this, when the battery has become fully charged there is a device which automatically stops the generator from charging.** The generator will not again start to charge the battery until the current in the battery drops to a definite point. This gives a protection against overcharging. A magnetic reverse current cut-out prevents the battery from discharging through the generator when the car is not in motion.

The motor is geared through a differential planetary set at a reduction of forty to one to the motor. It is fitted with a roller type of overrunning clutch and a centrifugally operated slipping clutch. The starting switch is of the two-point type. A non-grounded system is used and if battery ignition is used it is essential that this have a non-grounded primary also.

Some of the features of the control used in this system are worthy of note. The cranking, lighting and igniting systems can be locked in any position. The lights may be left on or off or any lights desired may be left burning. This control is in the terminal board, where all electric control is located. Another feature is the tell-tale light which glows when the generator is not charging and the engine is running. The battery may be tested also by this lamp. When fully charged the lamp will light up brightly when a button is pressed.

Electro—Single Unit System

The Electro system has a unit starting motor and lighting and ignition generator, the dimensions of the instrument are 16 5-16 inches base length, 5 3-8 inches wide and 8 5-8 inches body height. The weight of the motor-generator is 100 pounds. It is necessary to arrange the motor with a short driving shaft integral with the motor case, driven either through the timing gears or silent chain and connecting to the starter with an Oldham coupling. The motor-generator is always in operation. When turning below 380 revolutions per minute it is a motor and when turning above that rate it is a dynamo or generator. The compound differential winding takes care of the output from the generator. No reverse cut-out is provided to disconnect the battery from the motor-generator entirely at very low speeds. Instead of this the ignition switch breaks the line between the battery and generator when the motor is stopped by cutting off the ignition.

The system operates on 24 volts, but charges the battery at 6 volts. The amperage drawn by the 24-volt motor when turning over the gasoline engine varies with the size of the motor as in all systems. In the case of a 4.125 by 5.25, six-cylinder motor at a speed of approximately 55 revolutions per minute the running current was 90 amperes on a test. The compression on this motor was 70 pounds. It was shown on this same test that it was possible to turn the gasoline motor over for 1 hour and 23 minutes. The gear reduction between the motor-generator and the gasoline engine is twenty-five to one when starting and change automatically to a direct drive when the gasoline engine starts running.

Vehicles of Labor

THE dual motor truck exhibition in progress in this city this week is one of the best in the history of the motor truck industry in that evidences of conservatism, and building for a purpose, are seen on every hand; and there are general indications which show that the manufacturer is not trying to market trucks on a radical basis, but rather to sanely meet the requirements of individual transportation as they exist today.

The buying public of passenger cars has during the last 10 years become accustomed to seeking for the changes the same as the public looks for the varying fashions from season to season. This is but natural in the passenger car field, but it has not a place in the business transportation field. The buyer purchases a truck as a business proposition, and not as a social issue, consequently he is not interested in whether this year's product is the same as last year's, providing it does the work and gives the satisfaction that he demands.

Because of this condition the majority of the truck models on exhibition are little altered from a year ago, **the biggest changes consisting of bringing out additional models to supplement those of last season, to make the line comprehensive enough to meet all requirements.** This is a commendable move as it makes it possible for a large industrial house requiring trucks bearing from 1,500 pounds to 6 tons to equip throughout with the same make of vehicle, thereby greatly simplifying its service relations with the maker. Industrial concerns have already realized the additional complications necessary when operating half a dozen trucks of different makes in that it calls for so much greater knowledge in repair work, and so much greater complexity in carrying stocks of repair parts, etc.

That manufacturers are realizing more and more the necessity of conserving time is proven by the **numbers of rapid-unloading devices exhibited.** These in general assume one of two forms; first, the demountable body with the wheel stand on which the body can be slid instead of unloading, and second the trailer design in which the load-carrying part is supported on two wheels and at its forward end rests on the tractor. There has been general improvement in the tractor field during the year.

The influence of the National Association of Automobile Manufacturers and also the Society of Automobile Engineers on motor truck design shows itself in nearly every exhibit. The uniform guarantee plate is coming into general use, and should prove a constant reminder to the truck owner or driver that the truck is capable of carrying a limited load and that its speed should not exceed a certain maximum. The influence of these two organizations is also shown in reduced body weights and further in the fact that some manufacturers selling chassis without bodies state the chassis capacity inclusive of body weight, so that whenever a body exceeding a stated weight is put on there is a corresponding number of pounds cut off the useful load that the vehicle can carry. The more headway a movement of this nature can gain and the sooner it can get under way the better for the industry.

The truck buyer is being better provided for by way of tires than ever before. The dual rear is now almost universal in vehicles of over 1-ton capacity, and manufacturers of tires are apparently sufficiently satisfied with the situation to issue 10,000-mile tire guarantees. This has a double meaning: First, the tires have been improved, and, second, they are more adequately fitted for the service they have to perform.

The influence of the N. A. A. M. and S. A. E. and also the body builder is seen in the neater housing of brake connections, etc., beneath the frame level, making it possible to install standard bodies without interfering with any of the operating parts.

There are many other minor improvements: Brakes are larger and more accessible to adjustments; frame sections are generally wider, deeper, and of heavier gauge; not infrequently springs have wider leaves and more of them; axles are heavier in the majority of cases; there are many more governors fitted than heretofore and quite a few of them are inter-connected with the speed of the car rather than being controlled by the speed of the motor crankshaft; there is a gradual turning to left-side steering wheels, a movement which is slow but up to the present fairly certain; and in a résumé of the many other parts of the truck many detailed improvements may be found, such as fitting supplementary springs, larger grease cups, better cab protection for the driver, more robust radiators, and quicker demountability of component parts.

Eastern States Greatest Users of Electric Truck

One-Third of 10,000 Electric Commercials Now Used Produced Last Year

From an address by Arthur Williams, president of Electric Vehicle Association of America, before a Boston meeting of the New England section of the association on January 10.

WITH an encouraging and formidable array of figures witnessing the vitality of this comparatively new industry, it may prove interesting to consider its beginnings, its growth, and the means by which the latter has been brought about. Then, having reviewed events and facts accomplished, we may turn to the future which has already been predicted for electric vehicles, and consider methods by which today's great expectations may become the actualities of tomorrow.

Electric pleasure cars were built as early as 1893, and current-propelled trucks came into existence in 1897. That these forefathers of our present machines possessed disadvantages, we all know. They were clumsy, expensive, and not always dependable. Their storage batteries were heavy and useful only for short distances, besides requiring expert handling. Then, too, central station authorities looked with such indifference upon those horseless carriages that they set the price of current for charging purposes at almost prohibitive figures. But, in spite of all these difficulties, early electric trucks were by no means the utter failures which their opposers pictured them. They were the first commercial cars ever used and today several 1899 models—made by a firm in Hartford, Connecticut,—are still running. The original truck of the Central Brewing Company is still making regular trips through New York's streets, with a total cost of less than $100 a year for repairs.

Setting this fallacy aside, then, reasons for former public unbelief in the advantages of electrics may be summed up as: misrepresentation of the characteristics of such cars; general ignorance of their good points; lack of charging facilities; and—as I have already remarked—such deficiencies in the vehicles themselves, as clumsiness, inadequacy of batteries, and complexity of mechanism. Misrepresentation consisted largely of assertions that the electric was the rival of the gasoline car for any and all uses. The fact that charging stations were few and current very expensive served, also, as a deterring influence. Finally, people in general knew nothing about the special excellencies of current-fed vehicles for city and suburban needs.

Today, nearly all of these conditions have been changed, and this transformation has been wrought, for the most part, within the last 2 years. First of all, the electric motor car itself has been very considerably improved. Its imperfections have been wiped out; it has been made simple of operation, reliable, dependable. The average distance which a pleasure vehicle can now travel upon a single charge has been increased to about 65 miles, while, in certain instances, records of 100 have been made.

Everywhere electric vehicles are rapidly gaining popularity. **In New York, between July 1, 1911, and July 1, 1912, the number of such cars in use grew 45 per cent.,** while an authority on electrical affairs in Chicago estimates that **this method of trucking has increased 400 per cent. during the last 2 years.** At St. Louis, for the first 6 months of 1912, one central station reported a gain of about 37 per cent. in income from charging cars.

The Public Service Corporation of New Jersey has kept a most interesting and careful record concerning the adoption of power-driven vehicles in its territory during the past two years. At the beginning of 1911, only about eighty pleasure cars were discovered, many of these being old models seldom used. The total number of electrics in the territory was about 139, the price of current for charging them being a little more than four cents per kilowatt hour.

Since the Public Service Corporation entered upon its campaign of pushing electric vehicles, **the total number of them in its neighborhood has risen from 139 to 440, and the cost of current has dropped from slightly more than 4 cents per kilowatt hour to an average of a trifle over 3.5 cents.**

The foregoing instances, illustrating conditions in various parts of the country, serve to show that, very generally, the power wagon has made tremendous strides during the last 2 years. Today some 30,000 of them are in operation in the United States, about 20,000 of these being for passengers, and about 10,000 serving commercial purposes. **One-third of this entire number were produced and marketed during the past year.** Oddly enough, perhaps 80 per cent. of all electric trucks and delivery wagons are being used east of the Alleghanies, **while by far the heaviest demand for pleasure vehicles comes from the Middle West.**

Having thus presented to you indications of the recent spurt in the electric vehicle industry, I should like to turn your attention to the question: **What causes have brought about this change?** As president of the Electric Vehicle Association of America, I am happy to say that I believe our society has had a large share in accomplishing these happy results. When the Association was formed, 2 years ago, current-propelled cars suffered from lack of concentrated effort to push them into public notice. Their makers found the cost of production high, owing to comparatively small sales; storage battery concerns had, accordingly, only a limited market for their output; and central station managers, seeing but little demand for current for charging, kept the price of such supply at discouragingly high figures.

Special attention should perhaps be called to an indirect result of the work of our organization. This is the steady decrease in the cost of current, owing to greater interest taken by central stations in electric vehicles and to the greater number of such cars in use. The price of current for charging 10 years ago averaged about 23 cents per kilowatt hour throughout the United States, while today it costs a little less than 7 cents with a reduction to about 4 cents for large consumers. Meanwhile the price of gasoline has risen steadily.

So much for the electric vehicle as it is today. Let us now turn our attention to its future, for the storage battery car has come to stay. Already, authorities are predicting an output of some 15,000 during 1913. They are, undoubtedly, desirable cars for city needs owing to their ease of operation in crowded streets, their low cost of maintenance, as well as their special adaptation for many stops, starts and waits. This is an important point, especially in delivery service.

An estimate has placed the amount of trackless hauling throughout this country at sixteen times as much as that carried on by railways. Of this, 80 per cent. is done in cities. Now, if electric propulsion were to be adopted for this work, it could be performed more quickly, safely and economically than by horse power, and this ought to result in reducing prices of many commodities.

Russian Trade Growing

In 1901 Only Forty Automobiles Were Imported But in 1911 the Total Jumped to 2717 Machines

There Are Only 5,392 Cars Registered in the Whole Country—90 Per Cent. Are in Cities

IN Russia the use of automobiles is growing, though slowly. In 1901 only forty automobiles were imported into Russia, and in 1902 still less, thirty-seven, but by 1906 the imports jumped to 245 automobiles and steadily rose from year to year, until in 1911 they reached the number of 2,717. The distribution of the importing countries may be seen from the following table for the year 1910:

Imported from	Automobiles
Germany	1,247
France	388
Great Britain	86
Austria	69
United States	49
Italy	20

This table tells us a very interesting thing. It is, of course, clear why Germany, with its proximity to the Russian market, should be able to market over 70 per cent. of the total yearly import, but for the United States export there is no reason to be particularly elated, notwithstanding the fact that as far as design and price go, the American product is at least as good as the German.

90 Per Cent. Are in Cities

The Russo-Baltic Car Company, Riga, Russia, has lately made an investigation as to the distribution of power vehicles in that country, and found that nearly 90 per cent. of all the automobiles in the country are registered in the large cities. Out of a total of 5,492 cars there are registered in St. Petersburg 2,654, in Moscow, 1,608, in Odessa, 377, and in Kieff, 190, or 88 per cent. in these four cities alone. A very large majority of these cars belong to private persons, and only 191 cars to the Government, out of this number 119 cars being registered in St. Petersburg. This figure is of considerable interest because, like most of the foreigners, American manufacturers spend a good deal of money and time in endeavoring to obtain government orders for automobiles, while the same amount of attention devoted to the general market would probably bring much better results.

As regards the kinds of automobiles used, there were found to be 306 motor trucks, and 4,040 passenger cars, including 641 taxicabs. The majority of the passenger cars are very low-powered, from 1 to 10 horsepower. In Moscow, 42 per cent., and in St. Petersburg as much as 48 per cent. of the cars are rated below 10 horsepower. The motor trucks are, on the contrary, comparatively high-powered, 48 per cent. being rated at between 21 and 40 horsepower, with an average horsepower capacity of 18.3. The reason for the low power of the passenger cars is partly the state of the roads and partly the Russian system of taxing automobiles. The cars cannot be practically used outside of the cities, at least not regularly, and even in the cities there are plenty of streets on the outskirts where an automobile will not venture during the rainy season. On the other hand, in all the large cities automobile owners have to pay a municipal tax of 1 to 3 roubles (50 cents to $1.50) per horsepower per year. Trucks pay in many places a lower tax than passenger cars.

The Russian army has a special Automobile Department and Automobile Corps, the latter consisting of about 400 men with an adequate number of officers.

As a matter of fact, what the Russian government would like to do is to buy automobiles of Russian make, and it is quite likely that ere long it will be able to do so. As early as 1899 a Russian concern, Leitner & Company, in Riga, started to build automobiles, but had to discontinue the manufacture partly owing to the small purchasing capacity of the market, but mainly because the cost of manufacture proved to be absolutely prohibitive, and it was very hard to find the highly skilled labor required in this class of work. Since then, however, a good deal of progress was done in the same city by the Russo-Baltic Car Company which began automobile manufacture in 1908, and is said to be fully capable now to build good cars. It builds two models: one with a four-cylinder, 24-horsepower engine, and the other with a 12-horsepower engine. Both models are of very rugged construction, and in this respect peculiarly adapted to runs on the bad Russian roads. The plant can build 200 cars now, but expects to have its facilities increased for the season of 1913.

The import duties on automobiles in Russia are 220 roubles ($116) for cars having four seats and more, 140 roubles ($74) for cars having less than four seats, and 75 roubles ($38) for automobile frames.

In general it appears that there is a market for the cheapest class of American cars in Russia; this market is not very large, but by no means negligible. What the manufacturers should go after, however, is not government orders, but the public. A good deal may be done in trucks and automobile supplies, the latter being now mainly imported from Germany.

Plantation Rubber in 1912

Auction sales of plantation rubber at London during the past year, with one series missing, amounted to 16,789 long tons. Estimating the final offering at 800 tons, the year's total would be 17,589 tons. This is considerably under the estimates made last fall when it was freely predicted that the total offerings of the year would amount to 20,000 tons.

In 1911 the total sales at auction were under 10,000 tons.

The course of prices has been generally downward since last January although the highest level was reached at $1.32 1-4 in March and the low average was 96 cents, established in November. Since then the market has been gradually rising in response to the check in offerings as the promised increases of large size failed to materialize.

The average price brought in 1911 was just over 5 shillings and in 1912 it was 4 pence less.

The plantation predictions for 1913 are for 40,000 long tons which would mean an average auction sale of 1,480 tons at each of the twenty-seven periods covered. The average of 1912 was 620 tons and in 1911 about 340.

No Automobiles in Odder

One of the oddest sights in Europe may be witnessed any day in the little city of Odder, Denmark. There are four thousand people dwelling here, but they have never relaxed from their earliest declaration, namely, never to permit the driving of an automobile through the streets. Consequently, a man in a business suit and a soft hat rides astride a black horse, which draws the motor car through the town. The operation affords great fun for the children, who pile into the automobile, even sitting on the laps of the chauffeur and occupants. A heavy fine attaches to any person attempting to violate the ordinance.

The roads of France, on the whole, do not compare in excellence with those of England. But it is an acknowledged fact that the condition of the roads of France has been growing worse during the last 10 years. Some charge it to steel-studded automobile tires, while others hint that the Government is lax in its duty of keeping the roads up to the mark.

Makers Mulcted by French Decision

PARIS, Jan. 10—In the case of the breakage of an important part of an automobile, involving personal injury, the manufacturer is responsible, and not the person from whom the car was hired, according to a decision just handed down by the Paris Court of Appeals. The decision arose out of a claim made by Mr. Strowbridge, of Philadelphia, for $100,000 damages for injuries received in a car rented from the Société Routiere.

Three years ago Mr. Strowbridge was touring through the Pyrenees in a car hired at the rate of $35 a day, when, on passing through Moret-de-Marsan he was thrown out of the car and seriously injured owing to the jamming of the steering gear. As a consequence of the accident Mr. Strowbridge had to have both legs amputated. The Court of First Instance awarded Mr. Strowbridge $14,000 damages against the hiring company, refusing to admit the plea that the manufacturer was responsible. In the judgment it was stated that it was the chauffeur's duty to constantly supervise the steering gear.

At the Court of Appeals this decision was amended, the judgment being given that the manufacturer was responsible for any constructional defect, and that the chauffeur, not being an engineer, must rely on the proper initial construction of the automobile. Therefore the manufacturer of the automobile, and not the hiring company, was ordered to pay $14,000 to Mr. Strowbridge. This decision is one of considerable importance to automobile manufacturers for they have always claimed that their responsibility was limited to the changing of any provedly defective part. Such a clause is incorporated in practically every sales contract drawn up in Europe. The automobile having been hired in this case, the client had not signed any document releasing the maker from responsibility for personal injury.

Ascertaining Loss of Weights by Heating

Conradson determines the water content of heavy oils by the loss in weight on heating. However, he recognizes the fact that whenever a heavy oil is heated to a temperature of 100 degrees Centigrade some oil is volatilized and lost. Wright heats to 105 degrees Centigrade, Hurst to 220 degrees Fahrenheit, and Archbutt and Deeley to from 105 degrees to 110 degrees Centigrade. Davis saturates a tarred filter paper and heats to 110 degrees Centigrade, Patrick heats the oil until slight decomposition takes place and assumes the loss in weight to be a loss of water. Gavolovski has improved the evaporation method by using duplicate samples in tarred flasks. He leaves one flask open in the usual manner and attaches to the other a sulphuric-acid drying tube, which he states absorbs the water and allows the oil vapors to pass through unabsorbed. The difference in loss of weight on heating he assumes to be a water loss. Lowenstein dilutes with 95 per cent. alcohol and dries repeatedly on a water bath and then at a temperature of 105 degrees Centigrade to constant weight. The evaporation method, varied as described above, is approximate and applicable only to heavy oils and greases. Its accuracy even with heavy greases is questionable.

Iron and Steel Made in Sweden

The production of iron ore in Sweden in 1911 was 6,153,778 metric tons, of which 5,769,528 tons was directly usable ore, 3,060 tons bog ore and 381,190 tons concentrates. The concentrates resulted from the treatment of 813,973 tons of low-grade ore. Pig iron production was 634,392 tons from 112 furnaces, against 603,939 tons in 1910. Foundry and special pig iron amounted to 32,992 tons, Bessemer and basic to 408,591 tons, forge to 181,525 tons and blast furnace castings to 11,284 tons. One electric ore reducing furnace produced 10,065 tons. The output of puddled iron blooms and bars was 146,722 tons, and of steel ingots and castings, 470,867 tons. The total of crucible and electric furnace ingots was 4,195 tons. The total of manufactured iron and steel was 456,353 tons, against 465,062 tons in 1910.—*Iron Age.*

Comparing the goosequill with the steel pen and holder, the steel pen with the fountain pen and the fountain pen with the typewriting machine, it is readily realized that simplicity of construction does not always win out in practice.

Credit Extended to Club

Physician's Automobile Club of Vienna Adopts Course By Which Physician May Receive Car Before Payment

Car Is Maintained By the Credit Company at a Monthly Flat Rate of $110

A COURSE which will of necessity result in a considerable increase of automobiles used by physicians of that city has been adopted by the Physicians' Automobile Club, of Vienna, Austria. This club has undertaken to form an agreement with the General Automobile Credit Company, of the same city, whereby the latter concern acts as vendor for a machine bought by doctors and credits him to the extent of the price of the car, which he pays off in monthly instalments of moderate volume. Besides, the club offers to operate the cars for their owners at a very low monthly rate, fixed at a certain price.

The latter point meets with the ideals of many physicians who have had no experience with chauffeurs, the purchase of supplies, and so forth. While the club does not seek to influence the prospective buyers in any way, it acquaints them with the various makes suitable for their purposes. The automobile type ranging between 12 and 20 horsepower is being recommended to prospectives, the price of which varies in Austria between $2,000 and $2,375. When ordering the car, the physicians pay $600, and after delivery from $70 to $80 a month, including 1.5 per cent. on the money yet unpaid.

Flat Rate for Maintenance

The maintenance of the cars, as detailed below, is taken care of by the credit company at a monthly flat rate of $110, which is paid at the end of the month. The maintenance comprises efficient tire equipment at all times, supply of all necessary fuel and lubricants, regular wages, illness and accident insurance for the chauffeur, fire and liability insurance, garage and washing cost, charging of batteries to keep the electric lighting systems in operative condition at all times.

On the other hand, the physician closing a contract has to agree to the following: The automobile must not be used to travel more than 1,000 kilometers (621 miles) a month, as controlled by a reliable odometer. Every kilometer traveled in excess of the 1,000 mark must be paid for at the rate of 5 cents per. Only 150 kilometers (93.15 miles) out of the 621 miles a month must be made outside of the city limits. A price of 5 cents additional must be paid for every kilometer made outside of Vienna. This rule is founded upon the logical conclusion that the benefit of the low rates offered by the credit company should accrue to the medical profession and to physicians in their specific capacity as such, rather than to private individuals. [Note: How is the number of kilometers traveled outside the city limits to be controlled? Unless the doubtful process of relying on the statements of the car owners is adopted, success of this part of the scheme is hardly conceivable. We remember that Vienna has a very great number of exits impossible to control.—Ed.]

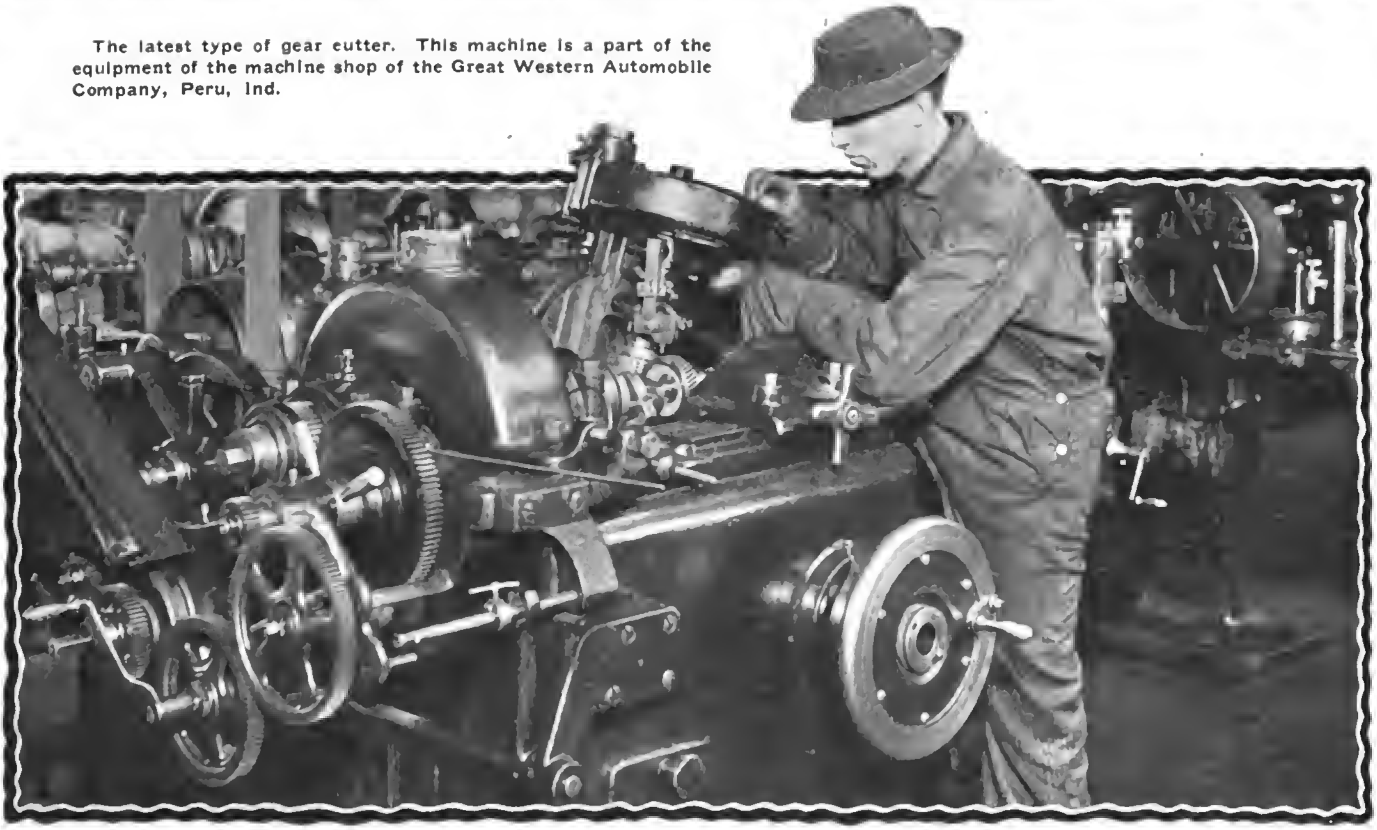
The Austrian regulations do not permit a Viennese doctor to work outside of the city precincts.

Another rule is that all repairs must be made in the shop of the credit company, where a moderate rate is charged for the work. If a car has to be laid up more than 3 days in the shop without the repair work being finished, an indemnity of $1.60 a day is paid to the owner by the credit company. Furthermore, if tire prices fall or rise more than 10 per cent. of the present rates, such an occurrence is to be sufficient ground for a proportionate change of the flat rate of monthly maintenance.

The physicians' club naturally believes that these easy conditions will cause many doctors to become users of automobiles.

Factory Miscellany

The latest type of gear cutter. This machine is a part of the equipment of the machine shop of the Great Western Automobile Company, Peru, Ind.



THIS machine will cut either spiral or spur gears and can turn out twenty finished gears a day, if they are put in the machine singly. If they are put into the machine in pairs, thirty-five may be turned out in one day. It takes but one man to run the machine and to take care of it. This machine will save time, because it turns out from three to five times as many gears as the older type of machine. The machine is automatic in its action and will stop as soon as the gear is finished. Besides the saving in time the machine saves space when considered in proportion to the number of pieces of work turned out. This is extremely important in factory work, where the amount of finished work turned out per square foot of floor space is to the highest degree important in the economical management of the factory.

JEFFERY-DEWITT Adds Plant—The Jeffery-Dewitt Company, Detroit, Mich., manufacturer of spark-plugs, will add a new factory, which will give that company 6,000 additional feet of floor space. The original plant will hereafter be devoted solely to the manufacture of porcelains and the machining of metal parts.

Waukesha in New Building—The Waukesha, Wis., Foundry Company, manufacturing brass and aluminum castings, has started operations in the building formerly owned by the Waukesha Canning Company.

Brown Sells Foundry—The Brown Commercial Company, of Peru, Ind., has sold its unoccupied foundry building there to the Peru Machine & Castings Company, and this concern will make all of the castings for that company.

Future Expansion in Beloit—The future expansion of the Stewart-Warner Speedometer Corporation's manufacturing facilities will take place at Beloit, Wis., rather than at Chicago, Ill., the site of the former Stewart Speedometer Company's works.

Oakland Plant Stops Work—Plant No. 1 of the Oakland Motor Car Company, Flint, Mich., was forced to suspend operations for a short time, due to high water. Pontiac Creek overflowed its banks and flooded the basement to a depth of 3 feet.

Calumet's Fire Loss—The Calumet Automobile Company, Appleton, Wis., sustained a loss of about $1,000 by fire, and eight cars and trucks were damaged by fire of unknown origin. The fire started near a work bench and communicated to the building.

Marathon Employees' Clubhouse—The Marathon Motor Works, Nashville, Tenn., has plans under way for one of the finest club buildings in the South. This club will be expressly for the employees of that company, and will have all the conveniences of the best clubrooms in that city.

Oliver Occupies Carhartt Plant—The Oliver Motor Truck Company, Detroit, Mich., has moved into the former Carhartt plant on Jefferson avenue and will continue the manufacture of the 1,500-pound, two-cylinder light truck and the 3,000-pound truck, which has been given a four-cylinder motor.

National Gauge to Build—The National Gauge & Register Company, LaCrosse, Wis., which makes gasoline and air gauges, is contemplating the erection of a new plant to cost $50,000. The present works are entirely inadequate to take care of the orders. The company is employing 80 men, and proposes to increase the force to 300.

Pennsylvania Rubber Enlarges—The Pennsylvania Rubber Company, Jeannette, Pa., is planning an immediate extension of its factory. At a recent meeting of the board of directors it was decided to erect a three-story addition to the plant. The new building will cover an area of 8,000 square feet, and will cost approximately $100,000.

Valkenburgh's Plant—C. J. Van Valkenburgh, of Chicago, Ill., is negotiating with the Commercial Club, of Sturgeon Bay, Wis., for the establishment of a works for the production of motor trucks designed by him. The city offers exceptional advantages for commercial propositions, due to its location on Green Bay and Lake Michigan.

Sprinkler System Efficient—The efficiency of the sprinkler system of fire protection for factories was well proven at the Kissel Motor Car Company's works in Hartford, Wis., recently, when an incipient blaze which might have caused great damage was effectually extinguished by the system which is carried throughout the big works.

The Automobile Calendar

Shows, Conventions, Etc.

Jan. 11-18.........Milwaukee, Wis., Annual Show, Auditorium, Milwaukee Autmobile Dealers' Association.

Jan. 11-25.........New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.

Jan. 18-25.........Philadelphia, Pa., Annual Automobile Show.

Jan. 21-26.........Toledo, O., Annual Show, Exposition Building, Toledo Automobile Shows Company.

Jan. 25-Feb. 1.....Montreal, Que., Montreal Automobile and Truck Show, R. M. Jaffray, Manager.

Jan. 25-Feb. 1.....Providence, R. I., Annual Show, State Armory, Rhode Island Automobile Dealers' Association, Inc.

Jan. 27-Feb. 1.....Philadelphia, Pa., Truck Show.

Jan. 27-Feb. 1.....Buffalo, N. Y., Annual Automobile Show.

Jan. 27-Feb. 1.....Detroit, Mich., Annual Antomobile Show.

Jan. 27-Feb. 1.....Rochester, N. Y. Annual Show, Exposition Park, Dealers' Association.

Jan. 27-Feb. 1..... Scranton, Pa., Annual Automobile Show, Hugh B. Andrews.

Jan. 27-Feb. 13....Troy, N. Y., Annual Show, State Armory, Troy Automobile Club.

Jan. 27-Feb. 1..... Waterbury, Conn., Annual Show.

Feb. 1-8...........Chicago, Ill., Annual Automobile Show, Coliseum and 7th Regiment Armory.

Feb. 3-8...........Washington, D. C., Annual Show.

Feb. 8-15..........Hartford, Conn., Annual Show, State Armory, Hartford Automobile Dealers' Association.

Feb. 8-15..........Minneapolis, Minn., Annual Automobile Show.

Feb. 10-15.........Chicago, Ill., Truck Show.

Feb. 10-15.........Winnipeg, Man., Show, A. C. Emmett.

Feb. 10-15.........Ottawa, Ont., Ottawa Motor Show, Howick Hall, Louis Blumenstein.

Feb. 11-15.........Binghamton, N. Y., Annual Show, State Armory. Dealers' Association, R. W. Whipple.

Feb. 15-22.........Albany, N. Y., Annual Show, State Armory, Dealers' Association.

Feb. 15-22.........Newark, N. J., Annual Automobile Show, First Regiment Armory, New Jersey Automobile Exhibition Company.

Feb. 16-23.........Richmond, Va., Annual Show.

March 24-29.......Indianapolis, Ind., Annual Automobile Show.

Race Meets, Runs, Hill Climbs, Etc.

May 30............Indianapolis, Ind., 500-Mile Race, Speedway.

Foreign

Jan. 11-22.........Brussels, Belgium, Annual Belgian Automobile Show, Centenary Palace.

March ....France, Sealed Bonnet 3000-Mile Run.

March 31..........Montevidio, Uruguay, International Competition of Agricultural Motor Vehicles.

April..............Barcelona, Spain, International Exhibition.

Wants Free Site—An automobile factory with a $100,000 capital wants a free site in New Martinsburg, W. Va., for a factory.

Auburn Erects Factory—The Auburn Automobile Company, Auburn, Ind., will erect a factory 60 feet by 80 feet, two stories high.

Allen Company Formed—The Allen Motor Car Company has been formed at Fostoria, O., and will manufacture cars ready for delivery in March.

Patterson Factory Progressing—Progress is being made in the construction of the Patterson Rubber Company's building, 250 feet long by 63 feet in width.

Beaver Erects Vancouver Plant—The Beaver Automobile Company, Portland, Ore., recently incorporated with a capital of $150,000, will erect a plant at Vancouver, B. C., to manufacture automobiles.

Quincy Plant Builds—The Machinery & Motor Company, Quincy, Ill., has been incorporated with $25,000 capital stock by Benner Kinsey, Fred H. Wilms and Harry V. C. Tingley, and will equip a plant at once.

Louisville Tire Factory Started—An automobile tire factory is to be started in Louisville, Ky., which will be conducted on a large scale. Mr. H. L. Lewman, of that city, has been elected president of the company.

Pilot Builds Addition—The construction of the addition to the plant of the Pilot Motor Car Company, Richmond, Ind., was connected recently, and ground for the new 120-foot building was broken. The new building will be two stories high.

Dayton Seeking Location—The Dayton Motor Truck Company, Dayton, O., is seeking a location in the South for a manufacturing plant, and it is probable an invitation will be extended the company to come to Gadsden, Ala., and look over the field.

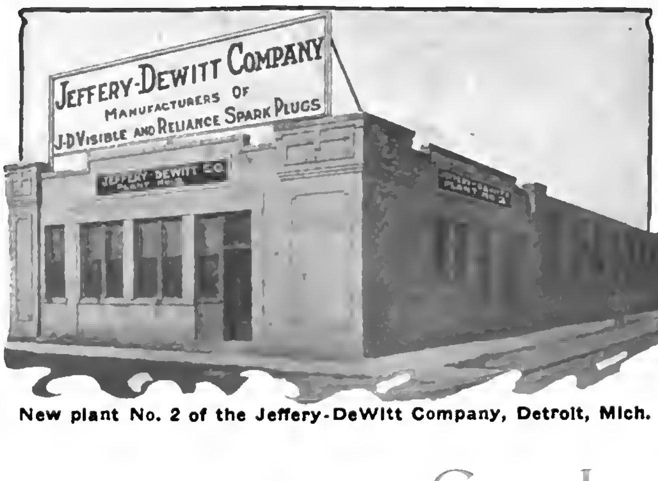
Moreland Plant Grows—The plant of the Moreland Motor Truck Company, Los Angeles, Cal., started in business but 18 months ago with modest dimensions. The factory is now enlarged to spread over 3 acres of floor space. January's output will be 60 trucks. The factory employs 250 men.

Klaxon for Factory Signal—The Critchley Machine Company, Worcester, Mass., has installed in its factory a Klaxon warning signal, which serves as the factory whistle. Similar uses of that signal have been found as adjuncts to the fire alarm systems of a number of other manufacturing institutions.

Bigger White Factory—Plans have been submitted to the White Company, of Cleveland, O., for the construction of a new factory building. They call for a one-story steel and brick structure, 160 feet by 240 feet. The new building is to be erected at the corner of St. Clair avenue and East Seventy-ninth street.

Bethlehem's Two New Buildings—Bethlehem, Pa., is to have two new industries that will give employment to many hands. The Packard Motor Car Company, Detroit, Mich., has decided to establish a storage house, paint shop and warehouse on the site of the old fair grounds, and with a capital of $100,000 the Bernston Steel Wheel Company has been organized, to locate there.

Michigan Factory Addition—New factory buildings now nearing completion at the plant of the Michigan Motor Car Company, Kalamazoo, Mich., will add a million square feet of floor space to the factories. When completed the Michigan plant will be among the six largest automobile factories in America. The new buildings are of three-story reinforced concrete construction, and will greatly increase the output of the cars.



New plant No. 2 of the Jeffery-DeWitt Company, Detroit, Mich.

News of the Week Condensed

Annual banquet of the Society of Automobile Engineers at the new Hotel McAlpin, New York City, January 17

SOUTH-AMERICAN Trade $100,000,000—Remarkable growth in the United States exports to South America from $38,500,000 in 1902 to approximately $138,000,000 in 1912 is shown in a statement issued recently by the Bureau of Statistics. The percentage of gain in the exports to that continent, the statement shows, is much greater than in the exports to any other grand division of the world. In Europe the exports in 1912 were $986,000,000, and 1912 approximately $1,490,000,000; to North America in 1902, $204,000,000, and in 1912, about $578,000,000; to Asia and Oceanica in 1902, $96,000,000, and in 1912 about $212,000,000.

Jenkins with MacManus—W. Haddon Jenkins has resigned as advertising manager of Motor Print to become merchandising expert for the MacManus Company, Detroit, Mich.

Schaefer Resigns—W. E. Schaefer, president of the Schaefer Manufacturing Company, Berlin, Wis., has retired as manager of that company to remove to his old home at Ripon, Wis.

Lee Heads Meet in Frisco—The heads of the different departments of the Don Lee Organization in California will meet for a general conference in San Francisco, Cal., on January 13, 14 and 15.

Thompson Resigns—J. Royden Thompson, a member of the William Thompson & Company, St. John, N. B., has resigned to accept the position of managing director for the Maritime Motor Car Corporation, whose factory is now nearing completion.

Drum Keeton Production Manager—Charles Drum, connected with the production department of the Packard Motor Car Company, Detroit, Mich., resigned recently to accept the position of production manager for the Keeton Motor Company of that city.

Eau Claire's Show—The first annual automobile show for Eau Claire, Wis., will be held from February 25 to 28 in the armory. It will be under the auspices of the Eau Claire Automobile Dealers' Association and thirty-five makes of cars will be represented.

Tiffin's Show on March 5—The third annual automobile show to be given under the auspices of the Tiffin Daily Advertiser, of Tiffin, Ohio, will be held March 5 to 8, inclusive. Sufficient floor space has been procured to show many lines of pleasure cars and trucks.

Frisco's Commercial Show—The San Francisco automobile dealers during the last few years have been opposed to yearly exhibits of pleasure cars, but it is now announced by the Motor Car Dealers' Association of that city that they will hold a commercial vehicle show early in April. Mr. C. A. Blanchard is manager.

Car's Novel Use—W. T. Campbell, who owns a 1,000-acre ranch near Lexington, Ore., besides using his Michigan car for business and pleasure, has rigged up an equipment whereby he pumps water to four large tanks. He simply blocks the car, jacks up the back wheels and connects a belt to the pump with one of them.

Awards in Klaxon Competition—The $250 recently offered by the makers of the Klaxon, the Lovell-McConnell Manufacturing Company, Newark, N. J., for the twelve best letters explaining why the bulb horn should be discontinued as the customary signal in the equipment of the modern automobile, has been awarded as follows: First prize of $100 to F. A. Sears, Rome, N. Y.; second prize of $50 to Dr. A. C. Smith, Elberton, Ga.; and ten prizes of $10 each to ten other contestants.

Automobile Growth in Kentucky—The growth of the use of the automobile in Kentucky is reflected in the semi-annual report of Secretary of State C. F. Crecelius made January 1, 1913, to the State Auditor, H. M. Bosworth. The automobile clerk has collected in the year ending December 31, 1912, within $8,065.20 as much for licenses as was collected during the preceding 18 months, from June 13, 1910, when the law went into effect, until December 31, 1911. The total collected for automobile licenses in 1913 was $37,260.30. For the first year under the law, from June 13, 1910, to June 14, 1911, collections amounted to $23,340.50, and for the 18 months until December 31, 1911, they were $65,325.50.

Automobiles in Buenos Aires—A correspondent in Buenos Aires states that the latest obtainable statistics show that 4,150 automobiles are in use in that city. Of these 3,200 are private cars, 700 are taxis, 200 are used as delivery vans and fifty belong to the public authorities. As regards the countries of origin of these cars, it is computed that 50 per cent. are French, 20 per cent. Italian, 10 per cent. English and a similar percentage German, while Belgium and the United States divide the remaining 10 per cent. In the matter of horsepower, 40 per cent. are over 30 horsepower, 30 per cent. are from 20 to 30 horsepower, 20 per cent. from 10 to 20 horsepower and 10 per cent. unclassified.

Smith Transferred—A. H. Smith, formerly manager of the Cleveland, O., branch of the Ford Motor Company, has been transferred to Indianapolis, Ind., as manager of the company's branch in that city.

A Penitentiary Offense—The United States Senate recently passed an amendment to the District of Columbia code making it a penitentiary offense to remove an automobile without the consent of the owner.

Bonde Company Building—The Bonde Motor Car Company, of Fargo, Minn., is to build a two-story and basement automobile house, including storage, showrooms and repair plant. The building will be 25 by 125 feet.

Oakland Agents to Move.—John H. Earle & Co., Washington, D. C., Oakland agents, have leased 817 Seventeenth street, N. W., and after extensive improvements will remove from the present quarters at 1018 Connecticut avenue.

Laurance Closes Contract—L. E. Laurance, Stites, Idaho, has closed a contract with the Mill City Manufacturing Company, Minneapolis, Minn., to make the electric lighted and heated steering wheel which he has patented. The effect is produced by electric globes manipulated by push buttons.

Milford's Club—The owners of the greater number of the automobiles at Milford, Mass., met recently and decided to form an organization to be known as the Milford Automobile Club. A committee was appointed to draw up a set of by-laws and nominate officers.

Camp Resigns—H. B. Camp, director of sales promotion for William C. Robinson & Son Company, of Baltimore, Md., refiners of Autoline, has resigned his position to accept the managership of a Western banking and security house making a specialty of underwriting and financing automobile manufacturers.

Lee Tire Declares Dividends—At the meeting held at Conshohocken, Pa., on January 15, the directors of the J. Elwood Lee Company declared a semi-annual dividend of 4 per cent., and the directors of the Lee Tire & Rubber Company declared a semi-annual dividend of 3 1-2 per cent. on the preferred stock of that company.

Waterbury's Show Plans—Preparations are nearly completed for the second annual Waterbury, Conn., automobile show, which is to be held the week of January 27. Thursday is to be society day. More attention will be given the accessories and motorcycles this year. Several of the Hartford dealers are booked for space.

Mansfield Tire Elections—At the annual meeting of the stockholders of the Mansfield Tire & Rubber Company at Mansfield, O., the following officers were elected: Judge C. T. Grant, of Akron, president; G. W. Henne, vice-president and general manager; Jesse E. LaDow, secretary; W. F. Henne, treasurer. These, with Dimon Herring, William Isaly, Charles Hoffman and John Schauer, of Troy, will comprise the board for the ensuing year.

New Models in Summer—A pertinent suggestion which if carried out may change conditions in general in the automobile sales, was made by J. I. Handley, president of the Marion Motor Car Company, Indianapolis, Ind., at a banquet tendered him in Dallas, Tex., recently. He suggested that the manufacturers of automobiles change the dates of changing models from the summer to the winter months. This, he believes, will stimulate trade during the winter months.

Fifth annual banquet of the motor and accessory manufacturers, held at the Waldorf-Astoria, Wednesday, January 15

Standard Moves—The Standard Motor Car Company, Philadelphia, Pa., has removed to 662 North Broad street.

Dallas Has Two Trucks—Since the inauguration of the parcel post service two automobile trucks have been put to work in Dallas, Tex.

Tire Filling Company Moves—The Automobile Tire Filling Company, Philadelphia, Pa., has secured new quarters at 1422 Fairmount avenue.

Cincinnati Has Fire—The Fisher and Kruse Automobile companies, Cincinnati, O., suffered from fire recently. About $10,000 in damages was done.

Rambler Home Enlarged—The Philadelphia, Pa., home of the Rambler has been enlarged by the acquisition of the building adjoining it on the south.

Lester Transferred.—Tom E. Lester, for the past year manager of the Buick Company's house in San Antonió, Tex., has been transferred to Dallas.

Nichols Sales Manager—J. A. Nichols, Jr., has been appointed sales manager for the northwest territory for the Franklin Automobile Company, Syracuse, N. Y.

Overland's $8,000 Loss—Nine automobiles and six freight cars were included in the $8,000 loss incurred when fire destroyed a big loading dock at the Willys-Overland factory recently, in Toledo, O.

Wharton Manager—J. O. Wharton, formerly with the Studebaker Corporation, South Bend, Ind., has accepted the managership of the John Deere Plow Company retail automobile house in Dallas, Tex.

Schmidt Kelly Manager—The Kelly-Springfield Motor Truck Company, Springfield, O., announces the appointment of Henry Schmidt as manager of its new Seattle, Wash., branch, located at 511 East Pike street.

Planning Dallas Tour—Plans are already under way for the Farmers' and Ranchmen's tour to be conducted next summer by the *Farm and Ranch*, of Dallas, Tex. The tour will probably take place next July or August.

Erickson Superintendent—F. E. Erickson, who has been in the employ of the Universal Truck Company, Detroit, Mich., for a number of years, has become superintendent of the plant to succeed E. W. Dobson, who recently resigned.

Halff Company Moves—The Halff Automobile Company, Dallas, Tex., has moved into new headquarters on automobile row. President Halff has offices on the second floor and will transact the business in Texas from his Dallas headquarters.

Physicians Elect—The following officers were elected at the annual meeting of the Physicians' Motor Club, held in the Hotel Walton, Philadelphia: President, Dr. J. J. Robrecht; secretary, Dr. H. A. Sutton; treasurer, Dr. L. A. Adler.

Omaha's $750,000 Show—Three-quarters of a million dollars' worth of automobiles will be exhibited in the Omaha, Neb., automobile show at the Auditorium, February 24 to March 1. This announcement was made by Manager C. G. Powell, of the show. At the show last year $500,000 worth of cars were shown.

Rural Residents in Majority—According to figures compiled by Theodore B. Roach, president of the Copeland-Roach Motor Car Company, Watertown, Wis., 80 per cent. of the 236 cars sold by his company in the company's territory, comprising parts of three counties in south central Wisconsin, were purchased by rural residents.

Seven-eighths elliptic underslung spring on the Mitchell six chassis

Toledo Firms Combine—An event of considerable importance in Toledo, O., automobile circles took place recently when the United Motor Company and the Landman-Griffith Motor Sales Company merged under the company name of Landman-Griffith-McIntyre Company. Mr. McIntyre will assume the general management of the concern.

Hutcheson Buys Land—J. A. Hutcheson, president of the General Motor Car Company, of St. Louis, Mo., has purchased a plot of ground at 3116 Locust street in the heart of automobile row, and will improve it with three modern automobile stores. The buildings will be of reinforced concrete and fireproof, each with a frontage of 31 feet by a depth of 105 feet.

Michigan's Road Statistics—According to figures furnished by State Highway Commissioner Ely, Michigan has built 463 miles of roads in the last 6 months. The state has paid rewards on all but 100 miles, but all of the road has been accepted by the state. The amount of road built in the last 6 months is larger than the amount build during the first 4 years of existence of the state highway department.

Automobile Incorporations

AUTOMOBILES AND PARTS

Albany, N. Y.—Kupke Auto Renting Company; capital, $1,000; to rent automobiles. Incorporators: E. C. Kupke, R. E. Male, W. C. McCune.

Bridgeport, Conn.—Jones Pneumatic Tire Spring Company; capital, $100,000; to manufacture automobile parts.

Buffalo, N. Y.—Buffalo Automobile Sales Corporation; capital, $15,000; to manufacture and sell engines, machines, etc. Incorporators: W. J. Harris, W. U. Heverly, Maud MacDonald.

Boston, Mass.—The Norwalk Motor Car Company; capital, $75,000; Boston automobiles, etc. Incorporators: C. C. Smith, J. W. Briggs, M. A. Beaudet.

Brooklyn, N. Y.—Jack Rabbitt Auto Company; capital, $500; to deal in automobiles. Incorporators: Frank Dunn, Donato Cella, Phillip Roth.

Brooklyn, N. Y.—Pratt-Hendricks Company; capital, $1,000; to deal in automobiles. Incorporators: W. H. Pratt, W. J. Hendricks, G. L. Robinson.

Buffalo, N. Y.—F. A. M. Auto Supply Company; capital, $20,000; to deal in automobiles. Incorporators: F. A. Marburg, J. B. Green, R. H. Templeton.

Chattanooga, Tenn.—Chaplin-Dille Motor Car Company; capital, $25,000; to manufacture and deal in automobiles and trucks, aeroplanes and other kinds of conveyances. Incorporators: B. M. Chaplin, M. C. Wildman and Jas. E. Dille.

Chicago, Ill.—American Motor League; capital, $2,500; to deal in automobiles and accessories. Incorporators: J. C. Garriott, Jr., G. T. Carver, M. L. Felkey.

Cincinnati, O.—The Hermes Motor Car Company; capital, $30,000. Incorporator: Albert Kleybolte.

Cincinnati, O.—Automobile Clearing House Company; capital, $2,500; to deal in new and second hand automobiles. Incorporators: T. A. Reilly, E. P. Bernardi, S. F. Bromley, A. M. Hirsch, J. B. Bromley.

Cleveland, O.—Alco Motor Company; capital, $10,000; to deal in automobiles. Incorporators: M. Kluger, C. K. Halie, Frank Butler.

Columbus, O.—Park Motors Company; capital, $30,000; to deal in automobiles. Incorporators: Scott Van Etteff, Charles Parkison, Amelia Van Etten.

Detroit, Mich.—Fuller & Son Company; capital, $100,000; to produce automobile parts.

Elyria, O.—The J. & H. Taxicab Company; capital, $2,500. Incorporators: A. L. Jackson, M. F. Harrison, Catherine Jackson, M. B. Harrison, L. B. Fauver.

Indianapolis, Ind.—The Wizard Motor Company; capital, $50,000; to manufacture motors adaptable to cycle cars. Incorporators: Orlando C. Forbes, Edward H. Habig and Park S. Florea.

Logansport, Ind.—Logan Auto Supply Company; capital, $25,000; to deal in automobiles. Incorporators: C. D. Billman, C. D. Pettigrew, O. A. Cummins.

Louisville, Ky.—The Standard Auto Company; capital, $25,000; to buy and sell machines. Incorporators: Geo. A. Dunham, Clifford L. Alderson and J. H. Alderson.

Madison, Wis.—Madison Gasoline Engine Company; capital, $15,000; to manufacture engines. Incorporators: W. C. Boutly, J. W. Proctor, A. C. Ledford, H. L. Wittiver.

Newark, N. J.—Universal Motor Truck Company of New Jersey; capital, $50,000; to deal in motor trucks, etc. Incorporators: John Kramer, Grace Cleveland and Pasquale Mauan.

New Haven, Conn.—Motor Truck Sales Company; capital, $10,000; to deal in motor trucks. Incorporators: J. F. Denison, H. F. Mabry, Howard Beach.

New York City.—Gildale Motor Corporation; capital, $30,000; to deal in automobiles. Incorporators: F. W. Strauch, T. P. Gilman, E. S. Peck.

New York City.—Duplex Gasoline Motor Company; capital, $200,000; to manufacture engines. Incorporators: G. W. Woodruff, A. P. Nevin, T. U. Parker.

New York City.—Bell & Waring Steam Vehicle Company; capital, $25,000; to deal in automobiles.

New York City.—S. J. Wise & Company, Incorporated; capital, $20,000; to manufacture automobiles. Incorporators: S. J. Wise, C. E. Van Vleck, Jr., E. M. Dalley, C. M. Kohn.

New York City.—Delivery Supervision Company; capital, $1,000,000; to manufacture and sell automobiles. Incorporators: Kenneth Groesbeck, Eben Luther, Hillman B. Hunnewell.

Borowitz Resigns—Joseph Borowitz has severed connection with the Durant-Dort Carriage Company, Flint, Mich.

By Way of Correction—In the January 9 issue of THE AUTOMOBILE, page 95, the Pilot roadster listed at $500 should have been $2,000.

Swords Hawkeye Manager—L. W. Swords has accepted the position of general manager with the Hawkeye Motor Car Company, Burlington, Ia.

Jacobson Opens Warehouse—I. M. Jacobson & Sons, metal merchants in Detroit, Mich., have opened a metal warehouse and works, located at 70 Catherine street.

Brouster White Manager—H. G. Brouster has become manager of the White Motor Car Company, the St. Louis, Mo., agents for the White line of gasoline cars.

Garrison Kelly Manager—The Kelly-Springfield Motor Truck Company, Springfield, O., announces the appointment of L. B. Garrison as manager of its Chicago, Ill., branch.

Shotguns Instead of Police—In the absence of any speed regulation in Montgomery, Ala., the citizens have adopted a shotgun policy to discourage speeding where pedestrians are endangered.

Gettysburg Roads Oiled—The Pennsylvania highway department is making preparations for the oiling of all the roads leading to Gettysburg in time for the unusual travel next summer.

Miller and Mills Take Miller—H. C. Mills and H. C. Miller, who were for years in the Diamond Rubber Company's sales organization, have taken the sales of Miller tires in New York territory.

Road Improvements in Caracas—Street improvements in Caracas, Venezuela, and the improvement of many of the country roads radiating from the capital, have opened a promising field for automobiles.

Stonewall Club Destroyed—The Stonewall Automobile Club building, country headquarters of the Winnipeg, Ont., Automobile Club, was totally destroyed by fire recently. The loss is estimated at $12,000.

Waterloo's New Club—Waterloo, N. Y., has a new automobile club, of which the first officers are: President, G. F. Bodine; vice-president, W. B. Lawrence; treasurer, F. G. Stewart, and secretary, S. C. Post.

Critchley Opens Engineering Department—J. Sidney Critchley, Carlton House, Lower Regent street, London, S. W., has opened a department for the introduction of engineering specialties into Great Britain.

Superior Club Elects—The Superior, Wis., Automobile Club elected new officers at its meeting recently: President, C. A. Erhart; vice-president, Dr. C. H. Mason; secretary, H. R. Corey, and treasurer, Dr. A. J. O'Brien.

Hartford Club Annual—Mayor L. R. Cheney was elected president of the Automobile Club of Hartford, Conn., at the annual meeting held recently. H. D. Maxim was chosen vice-president; Arthur Fifoot, secretary, and Albert M. Kohn, treasurer.

Louisville Show Date Changed—It has been decided to hold the sixth annual exhibition of the Louisville, Ky., Automobile Dealers' Association one week earlier than was announced at first. The dates have been changed from March 12 to March 5.

Shank's Crusade Against Speeders—Lew Shank, mayor of Indianapolis, Ind., has begun a personal crusade against violators of the speed laws. The mayor has twenty arrests to his credit in 2 nights, and he says the squad of motorcycle police will be reorganized.

Milwaukee Fisk Moves—The Fisk Rubber Company, of Chicopee Falls, Mass., has moved its Milwaukee, Wis., branch from 456 Milwaukee street to new and larger quarters at 450-452 Milwaukee street, several doors south. The change gives the company increased repair and stock facilities.

Kelly Moves—The New York City branch of the Kelly-Springfield Motor Truck Company, Springfield, O., has been moved to 239 West Fifty-sixth street. The major portion of this building will be devoted to company showrooms and service station. This branch will be in charge of A. S. Holly.

Good Roads in Texas—Financial provision has been made for the construction of an extensive system of good roads in El Paso County of Texas and a number of counties in New Mexico. The bond issue for good roads in El Paso County amounts to $390,000. In the adjoining county of Dona Ana, New Mexico, $100,000 have been issued for the purpose.

Automobile Incorporations

NEW YOAK CITY.—Webster-MaeGowan; capital, $50,000; to deal in engines. Incorporators: G. P. MacGowan, W. H. Webster, F. N. Dyer.

NAW YORK CITY.—Gas Saver Sales Company; capital, $25,000; to deal in automobiles. Incorporators: H. C. Fisher, J. H. Miller, Eugene Cable.

NAW YOAK CITY.—Pneumatic Hub Wheel Company; capital, $10,00; to manufacture pneumatic rubber cushion hub wheels. Incorporators: Kasiel Blau, George Dorfman, Walter Primoff.

NAW YOAK CITY.—Packard Lyric Renting Company; capital, $1,000; to rent automobiles. Incorporators: John Collins, Mary Collins, W. P. Schmuck.

NEW YORK CITY.—Co-Operative Sud Car Company; capital, $3,000; to deal in automohiles. Incorporators: J. B. Bauer, Louis Ezeehlel, John Curtis.

NAW YORK CITY.—F. M. Randall Manufacturing Corporation; capital, $5,000; to manufacture motors. Incorporators: F. M. Randall, L. B. Rosenberg, J. C. Weschler.

NIAGARA FALLS, N. Y.—Power City Auto Company; capital, $5,000; to deal in automobiles. Incorporators: Eugene A. Kinsey, James M. Donohue, Augustus G. Porter.

PINEVILLE, KY.—The Cumberland Motor Company; capital, $50,000; to manufacture spring motors.

QUEENSAORO, N. Y.—Elite Auto Wagon Company; capital, $5,000; to manufacture motor trucks. Incorporators: S. A. Hartogensis, Leo Loek, R. S. Hartogensis.

QUINCY, O.—Machinery & Motor Company; capital, $35,000; to repair automobiles. Incorporators: W. Gottleib, C. L. Cohns, H. Waldman.

RACINE, WIS.—The Perfex Radiator Company; capital, $15,000; to manufacture automobile and international eomhustible engine radiators.

ROCHESTER, N. Y.—The Ball Washburne Motor Company; capital, $25,000. Incorporators: Ward H. Ball, Charles H. Washburne and Asa R. Ball.

SHELBYVILLE, INO.—Hoosier Novelty Company; capital, $10,000; to deal in automobiles. Ineorporators: R. E. Baker, R. J. Patterson, J. F. Tierney.

SOUTH BENO, INO.—South Bend Auto Body Company; to manufacture automobile bodies. Ineorporators: Samuel Nicbolson, Stanley Nicholson, V. E. Paxson, J. C. Paxson.

TOLEDO, O.—Gauntlett Auto Sales Company; capital, $50,000; to deal in automobiles.

TOLADO, O.—Toledo Electric Company; capital, $25,000; to manufacture automobiles. Incorporators: G. A. Lay, J. B. Lay, J. Baerachi, E. X. Schaeffhold.

UTICA, N. Y.—F. P. Miller Motors Corporation; capital, $5,000; to deal in automobiles. Incorporators: H. R. Beebe, W. T. Cantwell, F. P. Miller.

WILMINGTON, DEL.—Pullman Taxicab Company; eapital, $100,000; to manufacture and sell and deal in and witb automobiles of all kinds.

GARAGES AND ACCESSORIES

CHICAGO, ILL.—Broc Electric Vehicle Company; capital, $12,000; to carry on a general garage and automobile business. Incorporators: S. N. Gotterman, Thomas C. Lyons, S. M. Corbett.

CLEVELANO, O.—The Forest City Garage Company; capital, $5,000. Incorporators: Christian Hertz, Edward T. Hertz and Emil C. Hertz.

INOIANA HAASOA, INO.—Harbor Garage and Machine Company; capital, $7,500: to carry on a general garage business. Incorporators: Gustave and August Jernherg, Charles F. Saluski.

JAMESTOWN, N. Y.—Peterman Garage Company; capital, $5,000: to do a general garage business. Incorporators: August Peterman, Otto G. Peterman, M. S. Peterman.

LINCOLN, NEB.—Omaha Automobile Club; capital, $10,000; to carry on an automobile club. Incorporators: S. A. Searle, Gould Dietz, B. V. Jewell, C. S. Gould, W. B. Cheek, P. A. Wells.

NAW YORK CITY.—Miller Tire Sales Company; capital, $5,000: to deal in automobile tires. Incorporators: H. C. Miller, Harrison C. Mills, W. A. Schenck.

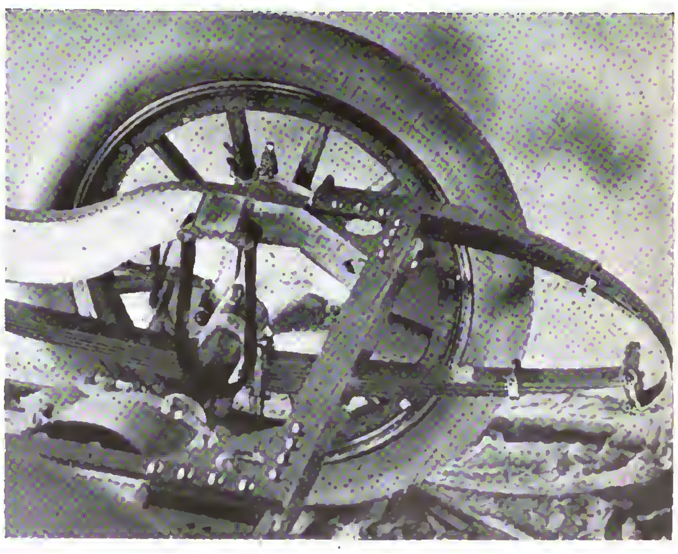
TOLEDO, O.—Sbriver Rubher Company; capital, $50,000; to operate a manufacturing and wholesale business. Incorporators: C. A. Shriver, L. H. Shriver, A. G. Florian, E. A. Florian, C. G. Goeltzenleuchter.

CHANGES OF NAME AND CAPITAL

CHICAGO, ILL.—Garfield Automobile Company; change of name to J. C. & S. Company.

DETAOIT, MICH.—Nortbern Auto and Machine Company; cbange of name to the Northern Auto Company.

SYAACUSA, N. Y.—H. H. Franklin Manufacturing Company; increase of capital from $300,000 to $1,5C0,000.



Three-quarters elliptic rear spring on the 1913 Stevens-Duryea C-6

AUTOMOBILE **Heater**—In which the waste heat carried by the exhaust gases is utilized for warming the interior of the car.

The subject matter of this patent, an automobile heater, is shown in Fig. 1. It consists of a valve casing which has a port communicating with the atmosphere and which is connected with the exhaust pipe of the motor of the automobile. This valve is operated by a pedal controlled by the driver. A heater adapted for the passage of exhaust gas through it is connected to the casing by a pipe; another pipe connects the heater with the muffler and another pipe the casing of the muffler. A rotatable piston inside the casing forms the valve mentioned above and is adapted to open or close the atmospheric port of the casing and control a passageway to either the muffler or the heater while the atmospheric port is closed.

No. 1,050,230—to Lundy L. Peters, Tiro, O. Granted January 14, 1913; filed November 15, 1911.

Motor Car Top—Consisting of four vertical and six inclined supports to which the fabric is attached.

This patent describes a top construction illustrated in Fig. 1. In this top the fabric or material is held by ten supports, four of which are vertical when the top is in use and are directly attached to the body of the car, the two rear supports being attached permanently and hinged to the body, while the two front supports have hook ends which engage a bolt on the car. The rear vertical supports carry four auxiliary members or supports which form angles of approximately 60 degrees with the vertical support and lie in a plane with them, the connection between vertical and inclined members being such as to permit folding of the members over each other when the top is put down. The front vertical support has one auxiliary member extending forwardly and supporting a bow to which the front end of the top material is attached. The front unit is equipped with so-called keepers which serve for attaching it to the rear unit when the top is not in use.

No. 1,050,167—to Rudolf H. Pfaff, Ashtabula, O. Granted January 14, 1913; filed November 15, 1911.

Automobile Wheel Rim—Which is formed of a number of accurate sections having notches engaged by tongues of the adjoining sections.

This patent describes the tire rim illustrated in Fig. 3, which is used in combination with a wheel, its felloe and a tire supporter on the same, the rim connecting the supporter and the felloe. This rim consists of a main and an auxiliary section, a flange extending from the main section to the auxiliary and between the wheel felloe and the tire supporter. The rim is formed of a number of arc-shaped sections, the end of each section having its flange formed with an inwardly extending notch and the adjacent section with a tongue engaging that notch. Means are provided for holding the main and auxiliary sections of the rim together and to hold the tongue in engagement with the notch.

No. 1,050,624—to George A. Distelhorst, Leshara, Neb. Granted January 14, 1913; filed November 13, 1911.

Multiple-Tube Tire—In which the number of inflatable tubes fill the interior of the casing and are so conducted as to remain in definite relative positions.

In this tire a number of inflatable tubes are contained inside the circular casing which is fitted with beaded edges. The inflatable members are so formed that they bear on each other with their contact planes forming right angles to each other. To prevent relative displacement of these inflatable members corresponding points of the abutting faces of the members are connected by ball and socket joints.

No. 1,050,581—to Benjamin Walter, Livermore, Pa. Granted January 14, 1913; filed April 17, 1912.

Auxiliary Air Inlet—Consisting of a ball valve ordinarily closed by gravity and opening when the engine suction rises to a certain degree.

This patent refers to an auxiliary air admission valve admitting air at high speeds when the air entering the engine through the carbureter is not sufficient to give efficient combustion. This device consists of a valve casing secured to the intake pipe of the motor and communicating with a valve chamber which has an air inlet at its bottom. This inlet is normally closed by a ball valve resting on it, but which is lifted when the engine suction is materially increased. The connection between the valve casing and the intake pipe consists of an air-inlet nipple which extends from the casing into the intake pipe and is formed with staggered perforations.

No. 1,050,200—to James Madison Aubrey, Los Angeles, Cal. Granted January 14, 1913; filed October 28, 1911.

Automobile Ignition Magneto—Which includes a housing terminating in bearings for the armature shaft of the magneto.

This patent deals with the construction of a magneto frame, comprising a single casting, consisting of a base plate, a pair of end plates with axially aligned openings and a top plate connecting the end plates. A commutator housing is formed on one of the end plates, which housing has a top opening and a pair of openings for the brushes, in its side walls. The commutator housing terminates in a rectangular bearing portion designed to support the shaft of the magneto armature.

No. 1,050,503—to Bert Whelchel, Indianapolis, Ind., assignor to A. C. Ayres, Indianapolis, Ind. Granted January 14, 1913; filed May 12, 1911.

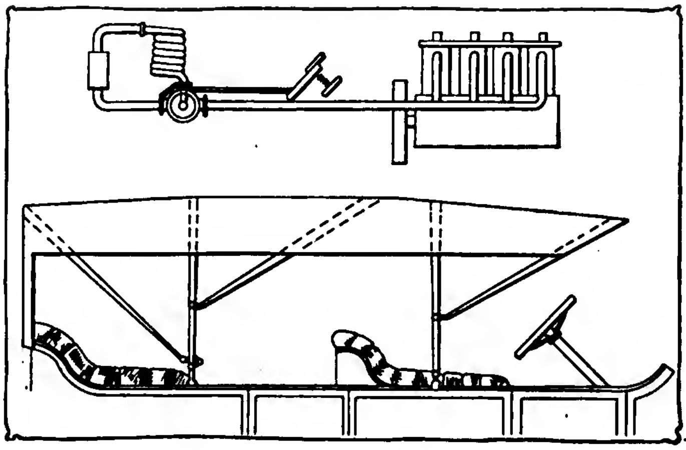


Fig. 1—Peters heater. Fig. 2—Pfaff automobile top

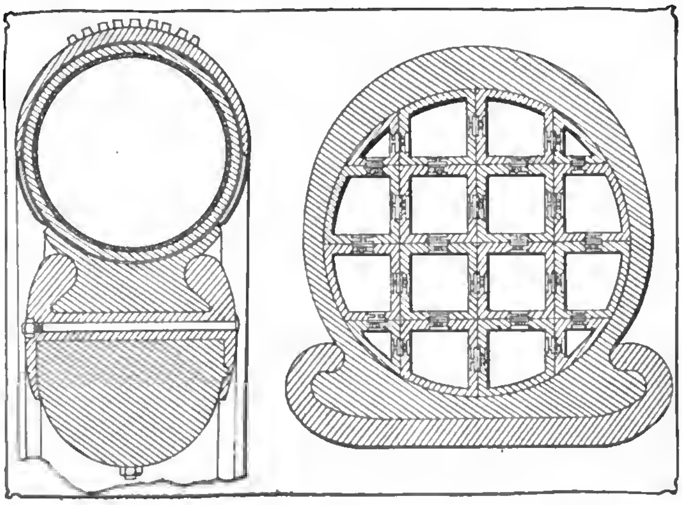

Fig. 3—Distelhorst rim. Fig. 4—Walter Multi-tube tire

VOL. XXVIII NEW YORK—THURSDAY, JANUARY 30, 1913—CHICAGO No. 5

The AUTOMOBILE

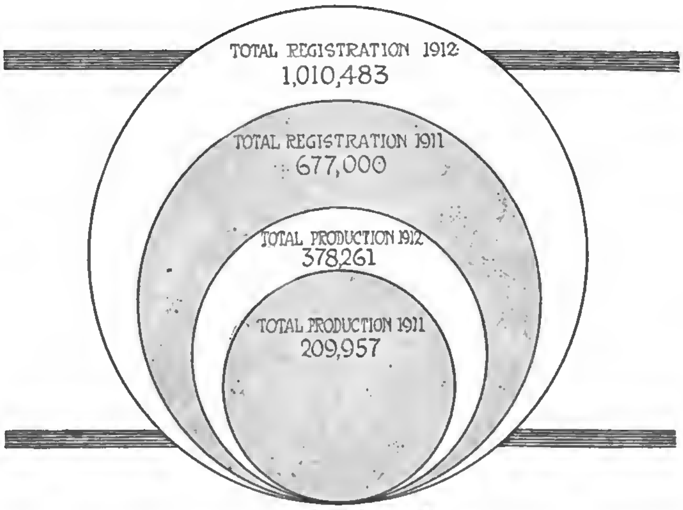
Car Registrations Now 1,010,483

This Figure Includes Duplicate Registration of 15,345
Makers' Statements Show Total Production of 378,261

By Donald McLeod Lay

GREAT as was the year 1911 in the annals of the automobile industry, the records established in registration and production of cars in the United States during that period have been surpassed by those created in 1912. The increasing interest which is manifested in the statistical reviews of the industry published from time to time in THE AUTOMOBILE rendered us especially desirous of securing as accurate figures as possible for our account of the progress made during the past year. For this reason, as well as because of the advantage of covering the entire year from January 1 to December 31 the annual article appears somewhat later than last year.

According to the figures given by the respective automobile registration officials of the various states the grand total of registrations this year, including pleasure cars and commercial vehicles of every description is 1,025,828. For the first time, however, THE AUTOMOBILE has been able to secure the number of duplicate registrations in each state, that is, the number of cars registered by non-residents. This amounts to 15,345, bringing the actual registration down to 1,010,483. The distribution of the cars throughout the union may be readily seen by referring to the table of registrations on page 329, in which the states are arranged alphabetically.



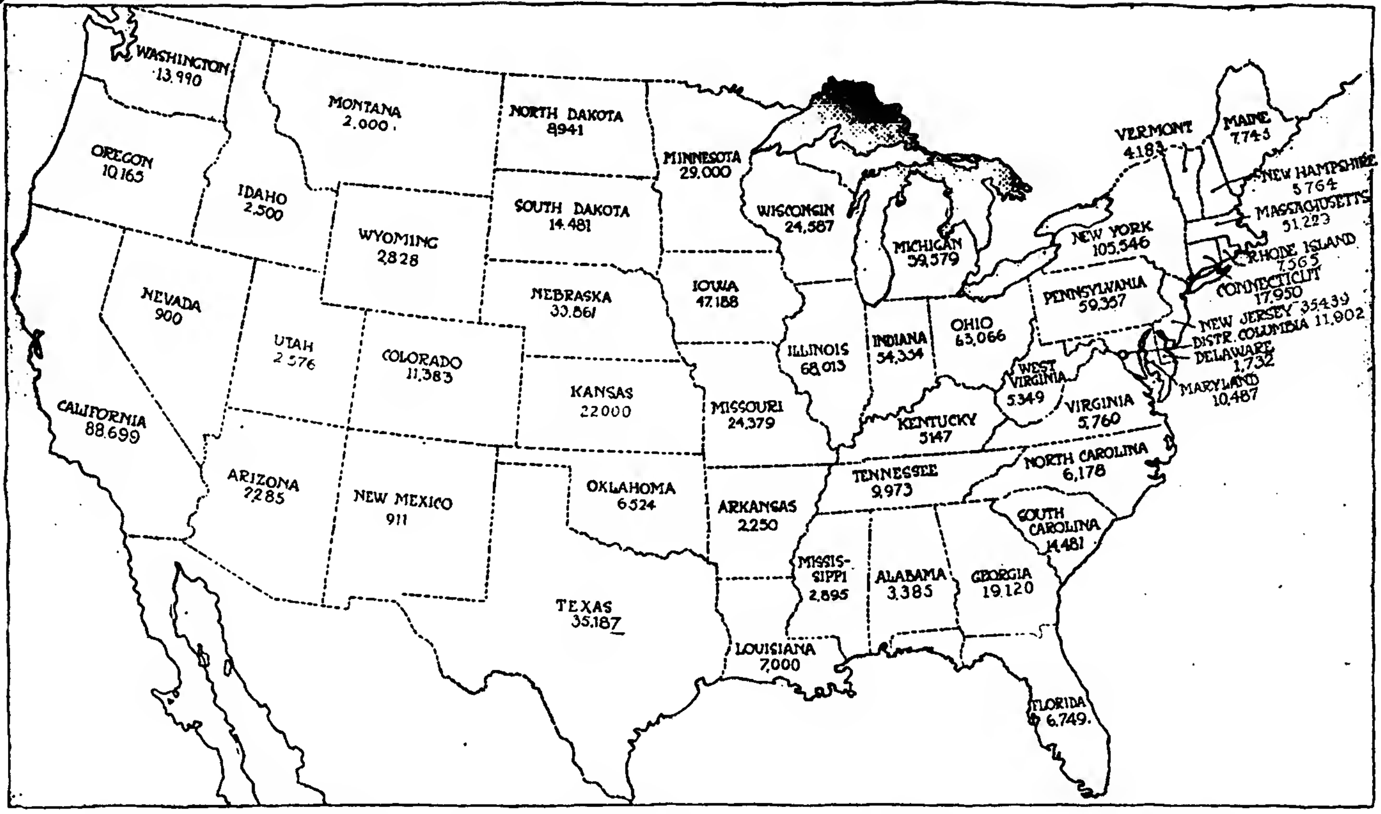
REGISTRATION IN EACH STATE

New York	105,546	Tennessee	9.973
California	88,599	North Dakota	8,975
Illinois	68,073	Colorado	8,950
Ohio	63,065	Maine	7,743
Pennsylvania	59,357	Rhode Island	7,565
Indiana	54,334	Louisiana	7,000
Massachusetts	51,229	Florida	5,749
Iowa	47,188	Oklahoma	6,524
Michigan	39,579	North Carolina	5,178
New Jersey	35,439	New Hampshire	5,754
Texas	35,187	Virginia	5,750
Nebraska	33,861	West Virginia	5,349
Minnesota	29,000	Kansas	5,147
Wisconsin	24,578	Vermont	4,183
Missouri	24,379	Alabama	3,385
Kansas	22,000	Wyoming	3,300
Georgia	19,120	Mississippi	2,895
Connecticut	17,950	Utah	2,575
South Dakota	14,481	Idaho	2,500
Washington	13,990	Arkansas	2,250
District of Columbia	11,902	Montana	2,000
Maryland	10,487	Delaware	1,732
Oregon	10,155	Arizona	1,524
South Carolina	10,000	New Mexico	911
Nevada	900		

The table shows the total registration of motor vehicles in the various states. Allowance is made for duplicate registration

Securing figures on production is by no means an easy task, but this year THE AUTOMOBILE was much more successful than last year in getting statements from the manufacturers as to the number of cars they built in 1912. Out of all the companies in business only nine refused to give the information and in these cases the figures were readily obtained in an unofficial manner. The total production during 1912, according to the sums given by the makers was 378,261, including all types of both pleasure and commercial cars. While these figures may seem very high to the uninitiated, the fact that the companies located in the city of Detroit alone produced over 200,000 cars will serve to show that the total for the country are fairly reasonable.

In answer to a request for an estimate of the number of cars which each manufacturer expects to produce during the year 1913. the figures given by the makers indicate an extremely sanguine state of mind, the total being over 600,000. THE AUTOMOBILE,



Map showing actual registration of automobiles in 1912 in the various states, excluding duplicate registrations

Distribution of Dealers, Garages, Repair Shops and Supply Houses

State	Dealers	Garages	Supplies	Repairs	Total
Alabama	73	37	1	5	96

Mexico	11	7	....	1	14
Total	13,408	9,299	559	779	18,547

however, regards this estimate as considerably in excess of the probable actual production which may reasonably be expected to amount to something between 400,000 and 450,000 cars. This figure is practically assured by the fact that one of the large companies has announced that it will increase its production by over 100,000 next year. The manufacturing facilities of this concern are such that this expansion is readily practicable.

In the statistical review of the industry published in THE AUTOMOBILE for July 25 it was predicted on page 165 that the value of the exports for 1912 would reach $25,000,000. This prediction was amply fulfilled. The total up to December amounted to the tremendous sum of $28,239,112, including automobiles and parts. This is an increase of $9,060,528. The imports of automobiles and parts, on the other hand, show a decrease in value of $147,275, the total for 1912 being $2,298,973. This indicates in a striking manner the increased appreciation of the American car by the American public.

In compiling the registration table on page 329 the figures given are those furnished by the registration officials of the various states excepting in Colorado, Idaho, Louisiana, Montana, Nevada and South Carolina, which have no provision for state registration of motor vehicles. The estimates for these states are based on population with reference to location and sectional registration and to estimates furnished by local authorities. The figures for Kansas, which also has no state registration, were obtained from the State Tax Commission, while those for Wyoming, also in the non-registrating class, came from the State Immigration Commissioner.

As before, New York leads the states in the number of automobiles registered, this time with a total of 105,546, none of which belong to non-residents. California is second with 92,199, but 3,500 of these are registrations of non-residents, which leaves only 88,699 actual registration. California has shown a big gain over last year, the difference being 29,497. This increase is greater than that of New York during the past year by 8,940. The great number of non-resident registration in California is readily explained by the large floating population due to so many residents of other states visiting the Golden State.

The states of New York and California, which have led all the others in automobile registration for several years are now not far apart in total registration. The growth of registration in the two states is graphically portrayed by the curve in the chart on page 331. The figures for New York state have been obtainable since 1901, but the chief point of interest in the curve is the sudden upward slant at 1903, which takes a more pronounced angle toward the vertical in 1909. The figures for California were not obtainable until 1910, but the curve indicates an even more rapid increase in the number of automobiles than in New York. It is interesting to note that the sharp upward slant beginning in 1910 on New York's curve is reflected in the equally positive direction of the California curve since 1911.

The number of automobiles registered in each state during the year 1912 as given in the table on page 329 is graphically illustrated in the diagram on page 332, as well as geographically in the map at the top of page 328, which shows the distribution of cars throughout the United States at the close of the year 1912.

Illinois stands third in the list with a registration of 68,073, an increase over last year of 29,969. This gain surpassed that of California for the year. Ohio is fourth with 63,066, which shows an increase of 17,327, and Pennsylvania fifth with 59,357, and a gain of 15,175. Indiana and Massachusetts are the only other states with a registration exceeding 50,000, the figures for Indiana being 54,443, or a gain of 17,508, and those for Massachusetts being 51,229, or a gain of 12,533. Massachusetts shows a non-resident registration of 858 over and above the figures given due entirely to its attractions as a touring state. Iowa is very close to 50,000 with 47,188, a gain of 19,252 over 1911. Michigan is ninth with 39,579, having increased its registration by 11,839, and New Jersey is tenth with 35,439. New Jersey shows a decrease of 12,827 over 1911 because of the fact that during 1912 it abolished the law requiring the registration of every non-resident automobilist who crossed its borders and fell into

RELATION OF AUTOMOBILES TO POPULATION

State	Cars per 1000 population	Population per car
Wyoming	22.6	44

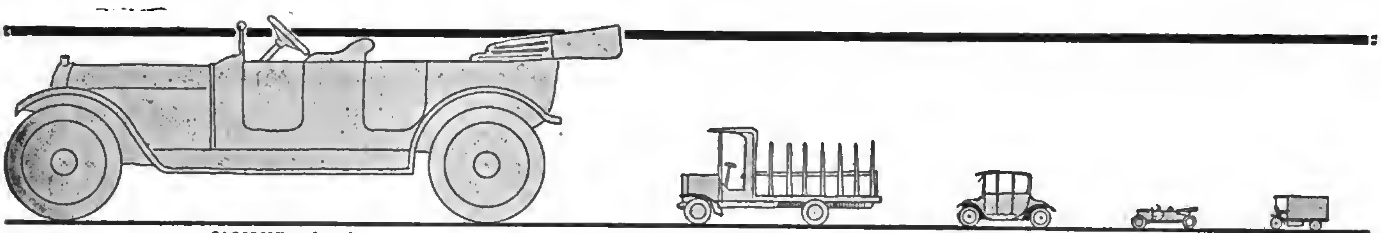
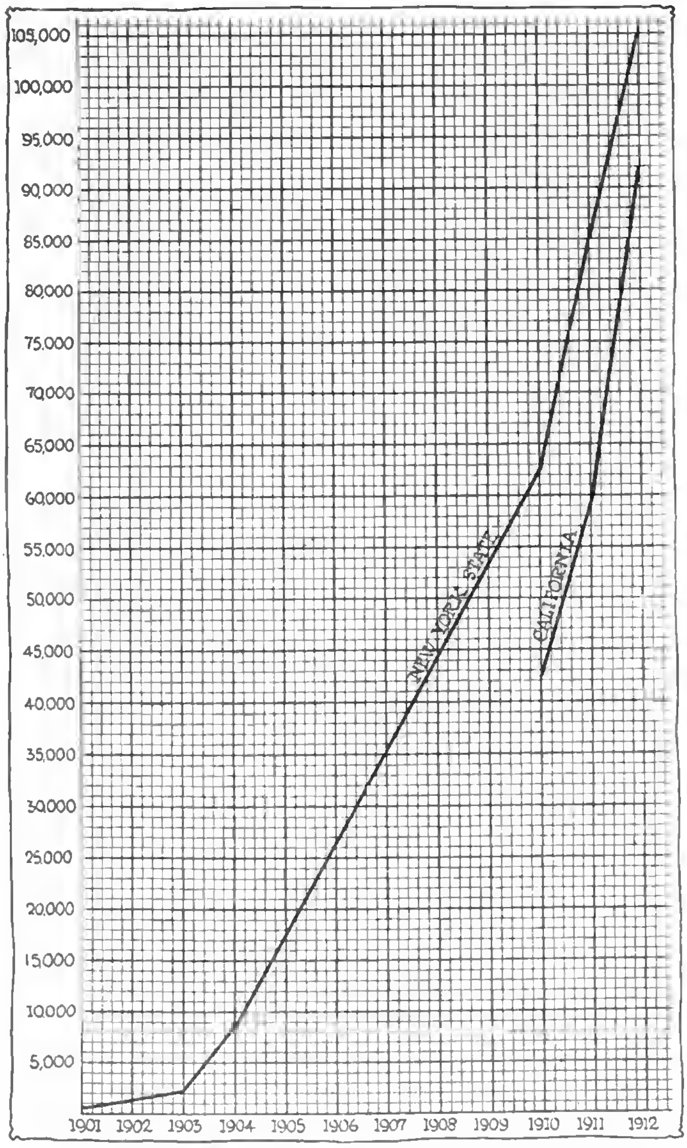
NOTE.—800 steam pleasure cars are included among the gasoline pleasure cars. Dots indicate that previous figures were doubtful. *The number of cars registered belonging to residents of another state. **Some figures from state registration officials, balance from estimates given by local authorities. †Estimated on basis of population with reference to location and sectional registration.



Proportional diagrams showing production of various classes of motor vehicles during the year 1912



Graphs showing the sharp upward trend of registration in New York and California, the two leading states in this respect

line with the other states granting non-residents touring privileges for a limited time. At the present time the non-resident registration in New Jersey is 7,617 over and above the registration figures given.

The other states follow in order as given in the table on the first page of this article. It will be noted that there are only seven states with a registration of over 50,000; only nine with a registration of over 20,000, and eight with a registration of 10,000 or over.

With regard to the other states having non-resident registration, that in the States of Alabama, Georgia, North Dakota, Ohio and Washington is a practically negligible figure, as may be seen from the table on page 329. That in the District of Columbia, 787, is readily explained by the number of non-resident statesmen residing temporarily in the District, while the 1,000 in Rhode Island, the 950 in New Hampshire, the 858 in Massachusetts, the 400 in Maine, and the 100 in Vermont are due to the great number of non-residents spending their summers or making extensive tours in those sections of the country.

In considering the registration figures, it must be remembered that there are a great many cars sold as second hand each year, the change of ownership requiring the issuance of another license. Thus the same car may be licensed twice in the same year. It is impossible to secure figures on this, but it is some consolation to know that this is balanced to some extent by the many manufacturers and dealers who have several cars registered on a single license.

According to such figures as are obtainable and the estimates of registrating officials in the various states the total registration, 1,025,828, is made up of approximately the following: Gasoline pleasure cars, 941,232; gasoline trucks, 49,691; electric pleasure, 29,268; electric trucks, 5,637. The total non-resident registration amounts to 15,345.

With regard to the relation of the number of automobiles in each state to the population, as may be seen in the table on page 329, the figures given by the State Commissioner of Immigration place that state at the head of the list with one car to every forty-four of the population, or 22.6 cars for every thousand people. In view of this fact and considering the comparatively small population of the state it would indicate that either the citizens of Wyoming are very prosperous or else that the figures given are somewhat high. Iowa stands second in car-population ratio with a car to each forty-seven people, or 21.3 cars per thousand population, and Indiana third with an automobile to every fifty persons, or twenty cars per thousand. The other states all have less than twenty cars to each thousand of the population. In this connection it is interesting to note that some of the states with large registration are very far down on the list, Illinois being fourteenth, New York sixteenth, Pennsylvania thirty-third and California thirty-seventh. The state having the fewest cars per population is Arkansas, which has one automobile to every 700 people, or 1.43 cars per thousand population. The states having over eleven cars per thousand of the population are shown in the illustration on page 331. Three of these have over twenty cars per thousand; Massachusetts over seventeen cars per thousand; North Dakota and Oregon over fifteen cars per thousand; Michigan, Minnesota and Rhode Island over fourteen cars per thousand; Ohio, New Hampshire and Kansas over thirteen cars per thousand; Washington, Illinois and Vermont over twelve cars per thousand; and New York, Colorado and Nevada over eleven cars per thousand.

In securing the output figures of the automobile manufacturers of the United States for the year 1912 letters were sent to every manufacturer throughout the country requesting the total number of cars produced, the numbers of each type, and estimate on the probable number of cars to be built in his plant during 1913. Most of the makers answered at once, giving the figures desired, and a second letter or an interview sufficed to obtain practically all the information.

When we totaled the figures given by the various companies as their output for 1912 we found that the automobile manufacturers of the United States, according to their own statements, produced a grand total of 378,261 cars and that they estimated

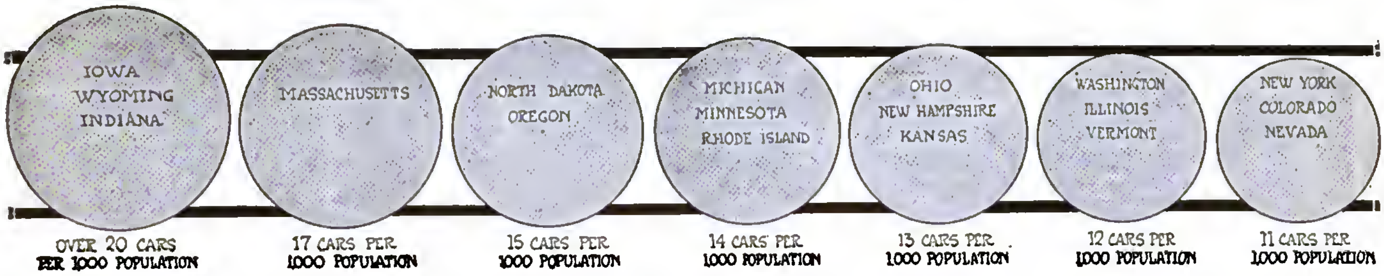


Diagram illustrating the popularity of the automobile in states having more than ten cars per thousand population

their output for next year at over 600,000, which, as has already been remarked, is probably at least 150,000 in excess of the number which will actually be turned out.

The grand total of 378,261 motor vehicles manufactured in 1912, according to the makers, is composed of 340,746 gasoline pleasure cars, 27,909 gasoline commercial motor vehicles, including some 200 fire department vehicles, 8,013 electric pleasure cars, 743 electric trucks and 850 steam pleasure cars. These compare with last year's figures as follows:

Types of cars built	1911	1912	Increase	Per cent. Increase
Gasoline pleasure	194,565	340,746	146 181	75
Gasoline trucks	8,500	27,909	19,409	224
Gasoline fire wagons....	105	200	95	90
Electric pleasure	5,634	8,013	2,379	42
Electric trucks	553	743	190	34
Steam pleasure	600	850	250	42
Total	209,957	378,261	168,304	80

If the manufacturers' figures are correct, and it is reasonable to suppose that they are not very far off the track, the biggest features in the way of increased class production are the gasoline pleasure car and truck classes, the first showing a gain of 75 per cent. and the second, the more remarkable of the two, a gain of 224 per cent. The growing partiality of the merchants and business men of America to the motor truck is evidently already having a strong influence on the production of the factories, which must increase their output in proportion to the increasing demand. This, of course, necessitates the enlargement of manufacturing facilities, a great deal of which has been in evidence for the past year. The percentage gains in production during the past year have also been noteworthy in each of the other classes.

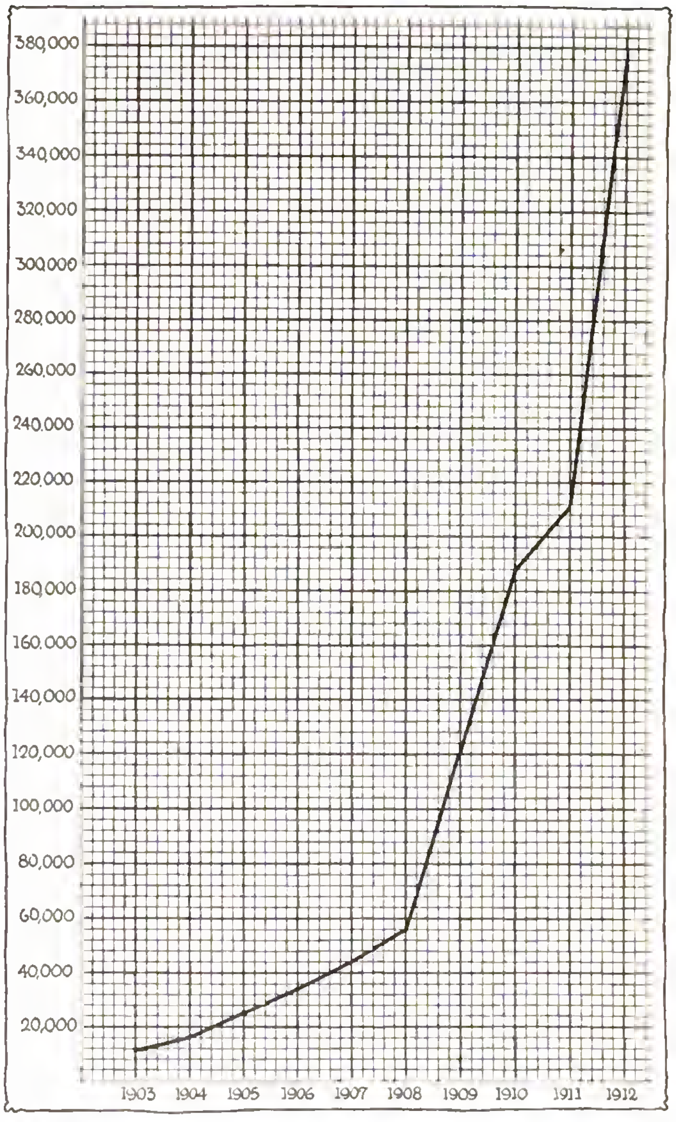
This year, for the first time, The Automobile was able to estimate the number of cars of various types produced selling at different prices during 1912, and has made an estimate of the number to be produced in 1913 in the same classifications. These are given in the table on page 332.

Disregarding the prediction for 1913 and dealing only with 1912, for which the figures are more reliable, we find that there were 164,678 gasoline pleasure cars produced to sell at $1,250 and under, the total amounting to $2,058,475. In the $1,250 to $2,000 class, 91,159 machines of this description were turned out, their sale netting the manufacturers $148,133,375. The $2,000 to $3,000 class was still more remunerative to the makers, the total of 61,179 cars amounting to $152,948,500. In the $3,000 and over class the sales of 23,730 cars brought the sum of $7,119,000.

Gasoline trucks selling at $1,250 and under were built during 1912 to the number of 12,885, which brought the manufacturers $12,885,000. In the second class, $1,250 to $2,000, 7,594 machines sold for $11,391,000 during the year. In the $2,000 to $3,000 class, 2,725 vehicles brought $6,812,500, while in the $3,000 and over class, 4,705 trucks sold for $14,115,000.

In the electric pleasure car field as well as in that of the electric trucks and steam cars, no machines were made to sell under $1,250. Taking the classification $1,250 to $2,000, 800 electric pleasure cars brought $160,000. In the $2,000 to $3,000 class, 4,487 cars sold for $11,217,500, while in the $3,000 and over class, 2,726 cars brought $8,178,000.

Electric trucks to the number of 292 were manufactured in 1912 to sell at $1,250 to $2,000, totaling $584,000. Those selling between $2,000 and $3,000 numbered 250, worth $625,000. There were only 201 electric trucks made to sell at $3,000 and over, but they brought $6[illegible]

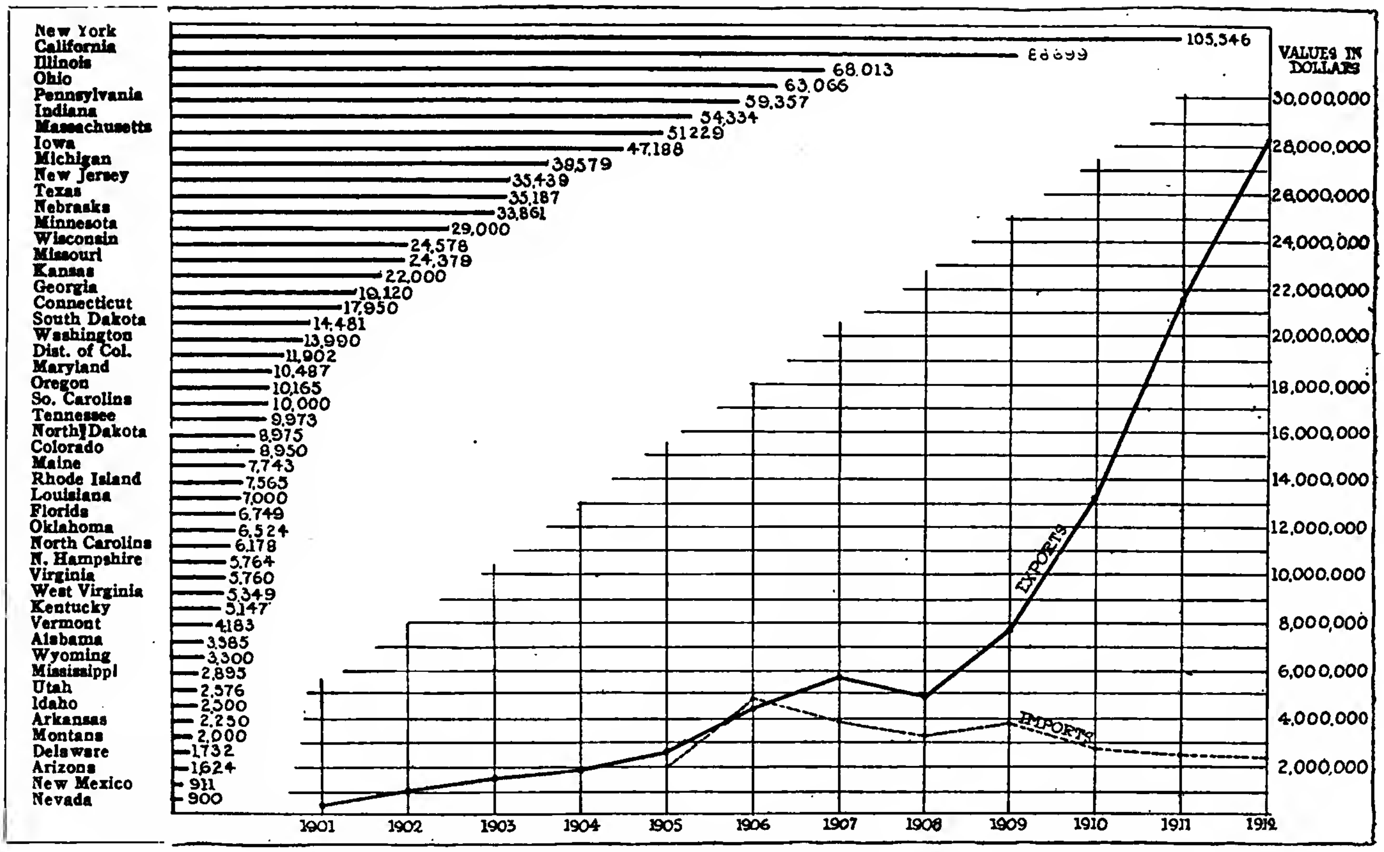


Annual production of automobiles for the past 10 years, shown graphically. The enormous increase during 1912 is clearly brought out

There were 600 steam pleasure vehicles manufactured in 1912 selling between $1,250 and $2,000, the proceeds being $975,000, while in the $2,000 to $3,000 class, 250 steam-propelled vehicles brought 625,000.

The total number of cars produced in 1912 to sell at $1,250 and under was 177,563, representing a value of $195,000,000. Those made to sell from $1,250 to $2,000 numbered 100,445 and sold for $163,000,000. Cars made to sell between $2,000 and $3,000 amounted to 68,891 and had a selling value of $172,000,000, while those commanding more than $3,000 totaled 31,362 and represented an approximate aggregate sum of $12,500,000.

At the present time there is some hesitation on the part of



Upper diagram shows registration in the various states, arranged in numerical order. Lower curve shows values of exports and imports during the past 12 years

NUMBER OF MOTOR VEHICLES OF VARIOUS CLASSES PRODUCED IN 1912 AND ESTIMATED FOR 1913 CLASSIFIED ACCORDING TO PRICE—MANUFACTURERS' FIGURES

the makers as to their immediate plans looking toward the 1914 season, largely on account of the uncertainty on their part as to what will be the policy of the new presidential administration. If the new president comes out emphatically in favor of good roads work throughout the country, the improvement of existing highways and the extension of cross-country routes, besides giving what the makers deem a reasonable tariff protection, the production of automobiles in the United States will be far greater than if the administration's policy should not coincide with these ideas. Just now the manufacturers are holding off somewhat, waiting to see what is going to happen.

In the export field, the makers of America acknowledge no superior in the number of cars shipped to foreign countries, although the automobile exports of France exceed those of the United States in value at the present time. It is expected, however, that within a year or two, the American manufacturers

will lead the world in value of exports as well as in the number of cars shipped to foreign shores.

Glancing over the table on page 333, showing the exports of automobiles and parts from 1909 to December, 1912, the steady increase in the number of automobiles exported to the leading foreign countries serves to bring out the fact that the American manufacturer, with any representation across the water, is by no means entirely dependent upon his domestic sales. Canada ranks first as the greatest user of our cars, having imported 6,864 machines from the United States valued at $8,255,134 during the first 11 months of 1912. This represents an increase of about 3,000 automobiles as compared with the previous year and an increased valuation of nearly $3,000,000. Ranking next to Canada is her mother country, the United Kingdom, which, during the past 11 months, received 4,371 American-made cars, valued at over $3,000,000. The valuation of the machines exported to the United Kingdom appears to have fallen off slightly when compared with the figures for 1911, although the number of cars has somewhat increased. South America received 1,859 automobiles in the first 11 months of 1912, while the comparatively large number of 3,112 went to British Oceania.

The import statistics for the first 11 months of 1912 show a decreasing number of cars of foreign make coming to this country. England appears to be in the lead in exports of cars to the United States, having disposed of 164 cars valued at $139,222.

An interesting graphic representation of the variation in exports and imports of automobiles from 1901 to 1912 is shown on page 332. The phenomenal increase in exports is clearly indicated, and, except for the slight decline for the year 1908, the curve has a steady rise. On the other hand, the imports curve is gradually off, the peak having been reached in the year 1906, and, while there appears to have been some slight rejuvenation in 1909, the decline, on the whole has been steady.

Receivers for Knox

Involuntary Petition in Bankruptcy Filed Against Company by Three Creditors—Each Gave Bonds in $15,000

Under New Policy Company Will Follow Lead of Other Makers and Lessen Number of Models

SPRINGFIELD, MASS., Jan. 27—Last Monday an involuntary petition in bankruptcy was filed against the Knox Automobile Company by three creditors which comprised the Samuel Eastman Company, Concord, N. H., $38; the Hartford Automobile Parts Company, Hartford, Conn., $757, and the Platinide Company, Providence, R. I., $2. This led to the appointment of receivers for the company, comprising E. O. Sutton, H. G. Fisk and C. C. Lewis, who have been carrying on the plant since Mr. Mayo's death. They each gave bonds in $15,000. The real estate of the company was given as valued at $250,000 and the value of the motor cars now finished or in process of being completed as $750,000. Since these proceedings the three receivers have appeared before Judge Morton, in the United States District Court, at Boston, and after explaining the situation relative to the company the judge approved an order allowing them to issue certificates to the value of $25,000 in order that the business might not be interrupted just at this time. This will act as a temporary financing of the company and allow the completing of cars and trucks for spring delivery and also give the company a chance to continue on the show circuit as it planned until the other resources are secured. When the money it is expected to raise from some capitalists is received the name of the company will be changed in the reorganization to the Knox Motor Car Company.

Under its new policy the Knox company will follow the lead of other makers and lessen the number of models. This will give the company an opportunity to utilize its plant to greater advantage. The truck section of the company has been growing rapidly in recent years and much attention will be given to this part of the production. With the aid of new capital to turn over the product now in course of construction and to increase production later the outlook for the company is much brighter than it was last year.

Yearly Dividend Reports

The Willys-Overland Company will pay an initial dividend of 1.5 per cent. on its newly issued common stock, on February 1. The Lee Tire & Rubber Company, Conshohocken, Pa., is declaring a half-yearly dividend of 3.5 per cent. on its preferred stock. The Buick Motor Company gave out its report on the year of 1912, during which the liabilities and assets, being equal to each other, were $12,271,200. The surplus of assets over liabilities for 1912 was $6,594,318, or $90,628 more than the surplus in 1911, which was $6,503,690.

Kelsey Sues Lycoming Foundry

HARTFORD, CONN., Jan. 25—Receivers of the Kelsey Motorette Company, Hartford, Conn., have brought suit against the Lycoming Foundry & Machine Company, of Williamsport, Pa., alleging breach of contract. The action is returnable in Pennsylvania.

Franklin Officers Are Elected

SYRACUSE, N. Y., Jan. 25—The H. H. Franklin Manufacturing Company and the Franklin Automobile Company, its selling organization, held their annual meetings Wednesday. John Wilkinson was elected vice-president of the H. H. Franklin Manufacturing Company, to succeed Giles H. Stilwell, and Mr. Stilwell was chosen vice-president of the Franklin Automobile Company in place of Mr. Wilkinson, the exchange occurring because since the preceding elections Mr. Wilkinson has become general manager of the manufacturing company, which owns the automobile company, the selling agency for Franklin cars. The manufacturing company's stockholders re-elected the following directors: H. H. Franklin, Mr. Wilkinson, Frank A. Barton, Mr. Stilwell, Edward H. Dann, Alexander T. Brown and Willard C. Lipe. The directors in turn elected Mr. Franklin president, Mr. Wilkinson vice-president and Mr. Barton secretary and treasurer. No change was made in the automobile company's officers, who are the same as for the other corporation, except the vice-presidency, and the fact that Messrs. Brown and Lipe are not members of the board.

Cox Not Infringing on Rose

Judge Hazel, in the United States District Court, Southern District of New York, rendered a decision in the case of the Rose Manufacturing Company, Philadelphia, Pa., vs. the Cox Brass Manufacturing Company, Albany, N. Y. The decision brought out the weakness of the patents owned by the Rose company, in a similar manner to the decision of Judge Cross rendered about a week ago. The lamp bracket made by the Cox company being the subject of the Rose complaint, Judge Hazel ruled that that bracket was quite different from the product of the complainant.

Big Attendance for Road Convention

From present reports the indications are that each of the forty-nine states will be represented, when the second Federal Aid

Automobile Securities Quotations

The developments of this week consisted principally in a falling off of the prices of tire stocks which had risen during the past few months. Among the stocks subject to this effect were: Ajax-Grieb common which fell 20 points and Miller, 10 points. International Motor preferred fell likewise, 15 points. On the other hand, Firestone common soared 23 points and Chalmers rose 5. The tone of trading was firm.

Good Roads Convention, called by the A. A. A., takes place in Washington, D. C., on March 6 and 7. So far more delegates have announced their intention of attending the convention than the total attendance of last year. This is accounted for to some extent by the fact that the inauguration will be held on March 4. But the good roads movement itself has become so widespread, that a successful and enthusiastic convention is assured.

Twenty-nine governors have already appointed delegates to represent their respective states at the convention and the boards of trade of the larger and more prosperous towns throughout the country have also appointed delegates. Groups of delegates from chambers of commerce and State trade organizations help to swell the numbers, and these taken in connection with the large groups of delegates from good roads organizations, the forty-five State organizations and more than 500 local clubs which are constituent bodies of the A. A. A. will make a record-breaking and enthusiastic crowd. In fact, indications point to a successful session.

Columbus Buggy Aifairs Straightening

Columbus, O., Jan. 27—Steps have been taken by the preferred stockholders of the Columbus Buggy Company, of Columbus, O., which was thrown in the hands of Daniel McLaren as receiver recently, to protect their interests and a meeting will be held January 30 for the purpose of organizing. In all there is $132,800 preferred stock issued and $700,000 common stock.

A committee consisting of John G. Deshler, a banker of Columbus, W. D. Brickell, a capitalist, and H. B. Peters, of Lancaster, O., will take up the question of looking after the interests of the preferred stockholders. It is believed that after paying all claims the preferred holders will be protected. Assurances are given that the plant will continue in the field of automobile manufacturing.

Market Changes for the Week

Tin proved to be the most important change in the markets of last week, starting at $50.50 on Wednesday, a gradual decline in price resulted ending on Tuesday at $49.90 per hundred pounds, due to a light demand. The prices were irregular for electrolytic copper in the domestic market, closing at a loss of $.008 1-8 for the week. Lead remained quiet but steady, closing at $43.30 per hundred pounds. Antimony was weaker, due to poor trade, and closing at $.08 1-4 per pound. The situation in the local market for scrap market underwent no change last week. Domestic rubber is still moving into consuming channels in a moderate volume, and there has been no increase in supplies. Cottonseed oil was steady, due to a short covering in January.

Fisk Company Expands

Recent $400,000 Addition to Company's Plant To Be Supplemented by Further Increase of Manufacturing Facilities

Personal of the Organization Will Remain Unchanged and Present Business Policy Will Be Continued

Owing to the rapid increase of business, the Fisk Rubber Company, Chicopee Falls, Mass., is arranging for a considerable increase of capital with the purpose of expanding its manufacturing facilities. The $400,000 addition to the company's plant which is now nearing completion will be supplemented by further improvements. Sidney S. Meyers, counsel for the company, states that the increase of capital is to be made solely on account of the enlarged facilities necessitated by the company's growth. The personnel of the organization will remain unchanged, H. T. Dunn retaining the presidency and H. G. Fisk the treasurership. The business policy of the company will be continued unaltered. A more detailed announcement of the company's plans will be made in the near future.

Maxwell Reorganization Progressing

The process of reorganizing the former United States Motor Company into the Maxwell Motor Company, Inc., is progressing rapidly and Sidney S. Meyers, counsel for the company, states that the securities and cash to be taken by the various classes of creditors, according to the agreement made at the time of reorganization, will probably be forthcoming by February 15. The company has moved its executive force to the United States Tire building.

Rubber Again Weakens

The principal topic in the rubber trade was the outcome of the auction of plantation rubber which was held in London. The sale went off at lower prices. There was a good demand, according to cables recently received, but the offerings were large.

Colt Defends Rubber Stock

The following statement was given out Jan. 27 by Samuel P. Colt, president of the United States Rubber Company:

"Judging from newspaper articles to which my attention has been called, several matters in the recent application of the United States Rubber Company to list additional common and first preferred stock were misunderstood. As stated in the application, which has been duly granted by the authorities of the Stock Exchange, $6,000,000 additional common stock is to be given in exchange for the entire common stock of the Rubber Regeneratnig Company.

"It is only fair that our stockholders should know at this early date that the entire earnings of the United States Rubber Company for this fiscal year promise to be largely in excess of dividend requirements. The earnings of the Rubber Generating Company are now double the dividends on the amount of the United States Rubber Company common stock issued in exchange for the corresponding issue of that company. Furthermore, the United Statea Rubber Company will undoubtedly, aside from earnings, be indirectly benefited to a large extent by the acquisition of the Rubber Regenerating Company.

"There seems to have been some misapprehension as to the amount of surplus shown in the statement of the United States Rubber Company to the Stock Exchange for the six months ended September 30, in comparison with the surplus shown as of March 31 last, in the annual report. Apparently it has been overlooked that in the meantime the company has declared and paid a stock dividend of $5,000,000 to its common shareholders. Obviously the surplua was reduced by that amount.

"To my mind the important point in this whole matter is that which I have already referred to, namely, that the earnings of the United States Rubber Company promise to be largely in excess of all dividend requirements"

Coleman Not to Resign

Contrary to the rumor which has been circulated recently throughout the trade, C. T. Coleman, president of the International Motor Company, New York City, has no intention of resigning from that office. Mr. Coleman and the other officers of the company denied this report emphatically.

Albany Active on Motor Legislation

Shows Throughout the National Circuit Report Good Progress—Many Exhibits Are Promised

Pelletier to Handle Accounts of Maxwell and Also Those of Splitdorf Starter and Other Accessories

FOLLOWING is an amendment to the highway law introduced by Mr. Wilson in the Senate of the State of New York, read twice and ordered printed, and when printed to be committed to the Committee on Internal Affairs:

§ 329-a. *Lights on vehicles. Every vehicle on wheels whether stationary or in motion, while upon a public highway or bridge shall have attached thereto a light or lights, to be so displayed as to be visible from the front as a white light and from the rear as a red light from one hour after sunset to one hour before sunrise; provided, however, that this section shall not apply to a vehicle designed to be propelled by hand or to any vehicle while the same is upon any lighted street or highway if the street lights are maintained at a distance of not more than five hundred feet apart, or to a vehicle designed principally for the transportation of hay or straw while loaded with such commodities. Upon the written application and presentation of reasons therefore by the owner of the vehicle, the state commission of highways may in writing, and subject to such requirements as it may elect to impose, but without expense to the applicant, except said vehicle from the provisions of this section for such period of time as the commission may determine. Nothing in this section shall be construed to affect the provisions of any existing statute, rule or regulation requiring lights on motor vehicles or affecting the obligations of operators or occupants thereof. A person violating the provisions of this section shall thereby incur a penalty of five dollars for each violation, to be recovered by the said town or village in which the violation occurs.*

Pelletier Takes Several Accounts

LeRoy Pelletier, who recently severed his connection with the Flanders Motor Company, Detroit, has been engaged by the new Maxwell Motor Company, Inc., the successor to the United States Motor Company, to write and handle the organization's advertising, according to a statement made by Walter E. Flanders, the new president of the Maxwell company. Mr. Pelletier is not to be known as advertising manager, but rather as advertising counselor. He will have his own headquarters separate from the Maxwell plant.

Mr. Pelletier has also been engaged by John Splitdorf to handle the advertising of a new concern which is to market an electric cranking apparatus to be brought out soon. He will also act for a tire company, the name of which has not been announced.

Safety Museum Publishes Booklet

The American Museum of Safety has brought out another small pamphlet devoted to the danger to children playing in the street. The attention of the little ones is called, in this publication, to the risk they run in playing tag, blindfold or never-touched-me, in a street where automobiles abound. Simply, but effectively, the pamphlet brings out the fact that the pleasure of playing a dangerous game is by far over-balanced through the chance of being killed or maimed by a vehicle. THE AUTOMOBILE co-operated with the Museum in producing the booklet.

Detroit Show Is in Full Swing

DETROIT, Jan. 28—With more floor space, more cars of every variety, more complete decorations and a larger accessory section than last year, the twelfth annual show of the Detroit Automobile Dealers' Association was opened to the general public in the Wayne pavilion and annex Monday night. The annex, which probably will remain as one of Detroit's show buildings, is 173 x 124 feet across Front street from the main pavilion, and gives the exhibit more than 10,000 more feet of space for exhibits than in 1912.

At the Detroit show 42 makes of gasoline pleasure cars are exhibited, each manufacturer showing several models, thus making the number of models on display something like 300.

The show marks the entry of Detroit into the National circuit, which now, besides Detroit, comprises eleven large cities of the country. For this reason many of the exhibits were brought direct from the New York show.

8,000 Attended Buffalo Opening

BUFFALO, N. Y., Jan. 28—Buffalo's eleventh annual motor show was auspiciously opened last evening at 8 o'clock when President George Ostendorf of the Buffalo Automobile Dealers' Association, under whose auspices the annual exhibition is being given, escorted Acting Mayor Burley.

The show is being held in the Broadway Auditorium, and is the result of weeks of effort and preparation. Seventy-five exhibitors are showing cars at the hall, and the approximate value of the cars on exhibition is said to total $2,500,000. About 8,000 were in attendance on the opening night.

Over 200 Cars at Newark Show

NEWARK, N. J., Jan. 25—With a record-breaking entry of more than 200 cars, of both the pleasure and commercial types, comprising no less than fifty-three separate and distinct makes, the drawings for space at the Newark Automobile Show were held Friday. In addition to those entries already in hand, there are several others still to be heard from, which will bring the list up to an even greater figure. The space in the huge First Regiment Armory, where the show is to be held during the week of February 15-22, was more than over-subscribed, but by the curtailment of the number of spaces that would be allotted to any one firm, the space committee arranged for several more exhibits.

Take Nothing from Maxwell Plant

INDIANAPOLIS, IND., Jan. 27—Judge Albert B. Anderson of the United States District Court for the district of Indiana has issued an order restraining the receiver, agents or employees of the Maxwell-Briscoe Motor Company from removing any of the property of the company at Newcastle from the jurisdiction of the court or from the place where it is now situated.

The restraining order was issued at the request of a number of Indiana creditors who recently brought action to have the company adjudged bankrupt. The restraining order, however, does not interfere with the transfer or sale of the property as recently ordered by the United States District Court for the southern district of New York.

Older Chauffeurs May Be Required

An act has been introduced in the Senate of the State of New York to amend the highway law to read that "no person shall operate or drive a motor vehicle who is under twenty-one years of age, unless such person is accompanied by a duly licensed chauffeur or the owner of the motor vehicle being operated."

Jerseyites Against Fee Increase

The members of the North Jersey Automobile Club passed a resolution on January 20, to protest against the increase in license fees proposed by Commissioner Lippincott. The reason of the protest is that the fees were raised 50 per cent. last year, besides a personal tax to the full value of their cars.

Organize To Fight High Gasoline Prices

New York Garage Association Sets Movement on Foot To Combine Efforts For Concerted Action

Purposes of Nineteen Thirteen Club Explained to Garage Association as a Ways and Means Committee

WHAT may be the beginning of a country-wide movement has been launched by the New York Garage Association. The fuel situation has aroused the indignation of a number of scattered organizations and it is the purpose of the garage men to combine these efforts into a concerted movement which will be productive at least of a thorough understanding of the subject.

At the annual dinner of the association held Tuesday night 200 garage owners were in attendance. Captain Louis J. Joscelyn presided. The enthusiasm of this body of men and their determination to make use of every means at their disposal to force the fuel situation to an issue was evidenced by the speakers, who insisted that a combined effort is necessary. Alfred E. Ommen, formerly City Magistrate, was the first speaker. He dwelt at length on the grip that the Standard Oil Company has on the industry in this country and how futile the efforts of one or two hundred garage men are against the mighty influence exerted by this immense institution whose profits are such that its stock sells for over $600 a share.

William R. Gulik, a chemist of Princeton University, was the next speaker. He said that the question is entirely one of supply and demand and that the price is bound to soar. He ventured the prophecy that there never would be cheaper gasoline and that the solution lay in a new fuel. Mr. Gulik has invented a fuel which he states will supplant gasoline.

Edward W. Mitchel, of the Hydrocarbon Products Company, announced that his concern has perfected a new process of refining which reduces the cost of production to an enormous extent. He stated that if he were assured of the patronage of the garage dealers of New York City, who represent the sale of 10,000,000 gallons of gasoline annually, his firm could put up a refinery which would produce gasoline to be sold at a price much lower than that now charged the consumer. Congressman Baker also spoke on the Turner process used by the Hydrocarbon company and stated that many oil fields at present unavailable on account of the large percentage of asphaltum could be made of use. Even Bermuda oil, which contains between 50 and 60 per cent. asphaltum, has been refined by the process, according to Congressman Baker.

Purpose of the Organization

T. H. Cochran, a political economist, said a few words in regard to the Nineteen Thirteen Club and its purpose, which is outlined in the following bulletin:

The First Nineteen Thirteen Club.

No Officers. No Dues. No Fees

Simply a *"Ways and Means Committee"* which will attend monthly meeting for the purpose of discussing a fully developed and specifically defined plan or other plans that may be suggested for the solution of many serious business problems now confronting the nation.

There is every indication that the year 1913 will be an eventful and prosperous one for the American people, provided every legislative representative without regard to political faith will heed the voice of the businsss men of the country for the general welfare.

The various questions affecting the economic progress of the country, business men as well as theorists differ, and as these questions to be correctly settled must be settled by business men, we hereby agree to join the above named club for the discussion of economic problems, to the end that our views may be of weight in the working out of practical business reforms through Congressional and executive action.

This organization, which is now registered with the county clerk of New York, will shortly incorporate under the laws of the District of Columbia, and then will charter state and sub-organizations. The attention of the organization is concentrated on the petroleum problem at the present time but will later spread to all industries, according to the plan of organization.

A meeting has been called for next Tuesday evening when the co-operation of the garage organization with the Ninteen Thirteen Club will be discussed along with the best means of getting an organized body into action.

Among the other guests and speakers at the banquet were the Hon. Earle Moore, of the Municipal Explosives Commission, who dwelt on the desire of the commission to meet the question of the installations of garage separators in a fair manner; Charles R. Zacharius, Theo. K. McCarthy, counsel for the organization; William Burrows, Wm. R. Haradon and Arthur M. Giegerich.

Aluminum Company's Wages $101,375

MANITOWOC, WIS.—The Aluminum Goods Manufacturing Company, Manitowoc, Wis., in making its annual accounting to the Citizens' Association of Manitowoc, which assisted in financing the enterprise, showed that there was an increase of more than 105 per cent. in wages paid during 1912 and of 60 per cent. in the number of employees during the first year. The requirement of the association in lending its aid was that the company guarantee to expend $350,000 in wages in the first 6 years of operation. During the first year, 1912, there was expended in wages $101,375. The payroll numbers 300 men.

Massachusetts Accidents in 1912

BOSTON, MASS., Jan. 25.—Police Commissioner Stephen O'Meara of the Boston Police Department has just compiled his annual report and a part of it is devoted to the traffic regulations and the use of motor cars in the city. The commissioner goes back into history and recites that the first instance of a prosecution of a motorist occurred 11 years ago when a man was convicted for driving without a permit in a public park. Since that time the prosecutions have increased to such an extent that the total for 1912 was 2170, showing an increase of 271 over 1911. Commenting upon accidents, the first report of which was made in 1900, the commissioner says:

"After long and careful personal observation, the daily study of complete official reports of accidents and prosecutions, and an extensive experience with complaints by and against owners and drivers of automobiles, I have formed opinions which I express as follows:

"The leap in four years, from six killed and 127 injured in Boston in 1908 to 22 killed and 483 injured in 1912 cannot nearly be accounted for by the increased use of motor vehicles, large though that increase has been.

"I believe that the principal cause of the growth of the list of killed and injured is the increase in the average speed of motor vehicles. To the same cause may be charged an enormous amount of anxiety, inconvenience and delay suffered by the walking public.

"In the past five years the police of Boston have made more than 10,000 prosecutions under the automobile laws. No one can say that they have been without effect. Doubtless they have placed some restraint not only upon the persons prosecuted, but upon many owners and drivers of automobiles who have never been before the courts. But to say that they have secured a general obedience to the law, or even obedience in a reasonable degree, would be to say what everyhody knows to be not true.

"The small fines imposed by the lower courts are paid, or the cases on appeal disappear in the mass of business with which the Superior Court is required to deal."

The American Motors Company, Indianapolis, Ind., has formally entered two American cars in the Indiana Automobile Manufacturers' Association tour from Indianapolis to San Francisco.

Two new entries have been received for the Speedway race at Indianapolis on Memorial Day—a Nyberg and a Keeton. The Nyberg will have 389 cubic inches piston displacement and will be driven by Harry Endicott. The Keeton car will be driven by Bob Buman, who is going to reduce the weight of the chassis to 1,600 pounds for the contest.

One of the principal items in the coroner's report for 1912 showed that during this year in the horougbs of Manhattan and the Bronx, New York City, there were a total of 2,712 deaths hy violence. Out of this number 146 were killed by automobiles. The coroner's office has represented strongly to the legislative authorities the necessity for stricter automobile laws, in the belief that a large percentage of the deaths were preventable. Fifty-one people, a woman among them, were arraigned for deaths by automobiles. Of these, four were held for tbe grand jury.

Col. E. F. Glenn, of Twenty-third Infantry, stationed at Fort Benjamin Harrison, has completed his plans for transporting that regiment from its station to the Pacific coast and back again, using motor trucks in the transportation. Each truck could carry eighteen men with their baggage and equipment. Additional trucks would be used for transporting oil, gasoline, extra tires, parts, etc.

Guatemala Has 200 Cars

All Are Owned in Guatemala City as Roads Throughout the Country Are Exceedingly Poor

None Were in the Country 4 Years Ago—Streets and Roads of Capital Are Good

GUATEMALA City, capital of the Republic of Guatemala, has 200 automobiles, but aside from those owned in the capital there are not five in the whole country. The reason is that the only roads serviceable for automobile use are those in and radiating from the city.

There are two taxicab systems in operation, using about ninety cars, and the remainder are privately owned. Taxicab rates are $50 an hour, which is quite reasonable when the rate of exchange, eighteen to one, is considered. There are two public garages where a majority of the cars are stored although several private owners have garages of their own.

German, French and a few American automobiles constitute the motor equipment of the city. The roads are very good, where they are good at all, and the use of the automobile is growing steadily. In fact there were no automobiles in Guatemala 4 years ago, and the present number really represents the growth of but 3 years.

Price of Gasoline Is Very High

The customs duties on cars and parts are 20 cents per kilogram (2 1-5 pounds). This tax is divided half and half between gold and Guatemalan currency, which makes the duty about 10.5 cents per kilogram. Thus on an automobile weighing 4,000 pounds, the duty would be about $190. But gasoline is very high, not only on account of the long transportation required, but because of the heavy duty imposed. The Guatemalan government exacts a tax of 5 cents per kilogram, half in gold, which amounts to about 5.8 cents per gallon, a trifle more in fact. This makes the wholesale price of gasoline about 32 cents, gold.

Treibel & Company, founded by an Americanized German, was the pioneer in the field and today represents five or six American factories and a foreign car or two. This house is in general merchandising.

La Perla, said to be the largest jewelry house south of the United States handles a number of foreign makes.

So far, the business in Guatemala City is too small to warrant exclusive automobile agencies. The city has a population of 110,000 and the people generally are prosperous and able to afford cars.

William C. Smith, Guatemala City, in speaking of the present disadvantages of American business men in trading with Guatemala and other Latin-American countries as compared with the favor of Germany, France and England, said:

"Careless packing, curtness in business communications and an all around disregard for the wishes and customs of Latin-America, are the chief elements that stand against the growth of American business in Guatemala and elsewhere in Central and South America.

"In the matter of packing, there is excellent reason why the Guatemalans want it done in a certain way. Take for instance, a shipment of general supplies for a plantation located in the foothills away from the railroad which spans the continent between Porto Barrios and San Jose. We will assume that the shipment weighs 10,000 pounds. If it has to be transported by mule back, it is necessary to have the parcels limited to 200 pounds each. Just before I left down there, such a shipment was received by a planter. He had ordered it from the United States and had specifically instructed the shippers to divide the parcels so that they could be handled by mules. Instead, the whole consignment arrived in bulk.

"Now the result was that the consignee was obliged to ship the goods by rail to Guatemala City, repack them according to his ideas and trans-ship them to the railroad point from which the mule train made its start. As it affects the United States, I can say with certainty that never again will this particular good buyer purchase goods in this country.

"Not only were his specific instructions disregarded, but when he inquired why such action was taken, he was curtly informed by letter that the company making the shipment could not be bothered with such unusual procedure.

"I recall another case where a mirror for the chief hotel was ordered from San Francisco. Of course, it was insured in shipment, but on three occasions mirrors to fill that order were broken on account of the lack of care taken in packing. The customer finally became wearied and ordered his mirror from Germany, receiving it in perfect condition at the first trial.

"I have seen bolts of cloth into which nails were driven in packing, ruining 10 yards or more.

"The results of all these things, carried on over a period of years have led to German commercial supremacy. This is a bad thing from the viewpoint of the United States and also Guatemala, because the great coffee plantations which are the backbone of international commerce are owned by non-resident Germans in large proportion who simply maintain working forces on the plantations, doing all business at Hamburg. The coffee is grown and shipped down to the coast and supplies are shipped back. The pay-roll is prepared in Hamburg. Aside from the comparatively small return for labor, not a cent of the coffee money reaches Guatemala. Recently the government added 1 cent a pound to the export tax in an effort to get back a share of the profits.

"The climate of Guatemala is different from other low-lying tropical countries. Geographically the republic is divided by the main continental mountain range. On either coast there is a low belt of land which from Colombia to Corpus Cristi has been noted for its unhealthfulness.

"Yellow fever has been a periodic scourge for many years, until about 7 years ago when the last visitation occurred. After that time President Manuel Estrada Cabrera has succeeded in stamping it out. The United Fruit Company which controls millions of acres of agricultural land along the coasts followed the suggestions of the United States officers who had studied the question of febrile hygiene and concluding that the mosquito was at the bottom of the epidemic, screened the open water within its jurisdiction and took other means to suppress the growth of the mosquito and the result is to be seen in the fact that for 7 years there has been no yellow fever in Guatemala. In the capital the climate precludes the possibility of fever on account of the altitude and it has never been considered a danger, but on the coast there has been a very different story to tell.

"Through President Cabrera the whole situation has been changed and in my opinion the chances of any epidemic of yellow fever in the future are practically nothing."

Speaking of automobile possibilities, Mr. Smith said that the average citizen of Guatemala City is in better position to own an automobile than the citizen of New York, from the financial viewpoint.

Tomlinson Takes Over Invader Oil

The manufacture of Invader lubricants for automobiles, including cylinder oils, greases, etc., which has been in the hands of Charles F. Kellom & Company, Philadelphia, Pa., is now being taken over by the Invader Oil Company, 80 Broad street, New York. The company is incorporated with a capital of $250,000 under the laws of the state of New Jersey and its officers are as follows: Charles F. Kellom, president; T. E. Tomlinson, vice-president and general manager; H. Dunthorn, secretary and treasurer. Other men affiliated with the new company are: D. A. Scheu, A. A. Francesconi, Howard Plowman, Harvey Wilkins, E. Kalkhof, A. Rafelson and F. Menke.

T. E. Tomlinson, who is known as the original promoter and manufacturer of Havoline and Wolverine brands, and owns a controlling interest in the Invader concern, when interviewed by a represetative of THE AUTOMOBILE, stated that in addition to the Philadelphia factory, which will be continued, a new factory for the manufacture of automobile lubricants will be opened in New York City next week. The address of this factory will be 92 Pearl street, right in the heart of the oil trade district. The Invader company will manufacture products obtained from 100 per cent. Pennsylvania oil bases and nothing else.

Mr. Tomlinson was emphatic in stating that his interests in the Invader Oil Company are his only connections with this industry.

Electric Cranking and Lighting

Part III

Continuing the Electric Systems Now Used by Makers of Prominent Cars—The Widely Differing Practices of These Makers Should Be Noted—Methods of Regulation Important

Subject Digest

¶ What system best meets the requirements of electric cranking and lighting? A study of those adopted by different car manufacturers reveals a widely varying difference of opinion. The use of the electric cranking motor is in its infancy, so experience in this field is limited.

¶ The watt consumption per revolution should be a decided factor in the situation where a purchaser starts often and does not run at a high enough speed to recharge the battery.

¶ The means of regulation of the current vary among the makers. There are so many of these means each claiming a small group of supporters that no definite trend towards a given method can be noted.

¶ Devices for protecting the cranking motor after the engine starts are of interest. The use of the overrunning clutch is very prominent for this.

¶ Where a motor generator is used many of the makers drive the generator at one speed and have an entirely different reduction betwen the engine and the generator when the latter starts to operate. The means for this change of gearing also vary widely, planetary gearing, eccentric gearing, etc., are used for this.

FOR the past two weeks THE AUTOMOBILE has published a review of the electric problem as it is presented to the automobile manufacturer and buyer. In the following pages the review of the principle systems which have been adopted by various makers and which have actually been installed on their cars, is continued. It has been pointed out in these reviews that electric systems may be made in three separate and distinct systems. The three-unit, the two-unit and the single-unit. The three-unit system is that in which the cranking motor, the electric generator and the ignition current generator or magneto are in separate units. The two-unit system is that in which any two of these devices are combined into a single unit. The single-unit system is that in which all three of the units are combined into one. When an electric motor and generator are combined into one, the resulting instrument is a motor-generator.

It is of interest to note in what manner the systems vary. The voltages range between the limits of 6 and 30. The one, two and three unit systems are all in favor and are used by several of the makers. Many prefer flywheel installations where the motor-generator becomes the flywheel, the rotating members performing the functions of a balance wheel. The different methods of mounting are of interest because they vary widely.

There is a spirit of unrest among the makers and they have not accepted as standard the starting and lighting system as it now stands. It is to be predicted that the next 6 months will see a wide change in the mounting of the electric starter and also a gradual adoption of one voltage. The use of 6-volt lamps and ignition seems to favor this voltage, but there are others who believe that the requirements of the electric motor act against a voltage as low as this.

Rushmore—Uses Three Units

The Rushmore is a three-unit system. To the lighting equipment which has been on the market for some time, a cranking motor has been added. The entire system operates at 6 volts. In the Rushmore system the amount of current supplied to the lamps and storage battery is kept constant by the utilization of a peculiar property of iron wire, when included in an electrical circuit, of greatly increasing its resistance when heated. This is clearly shown in Fig. 6, in which the upper curve represents the performance of an iron wire resistance and the lower that of German silver or other material whose resistance does not vary with temperature. It will be seen that in the former the resistance is practically constant up to a certain point, allowing the current in amperes to be proportional to the pressure or voltage applied. At this critical point, however, which corresponds to a dull red heat in the wire, the resistance suddenly increases enormously as shown by the sharp upward trend of the curve. A very largely increased voltage is then required to force a single additional ampere through the wire. This form of resistance thus provides a simple means of maintaining a constant current so long as the voltage is not below that required to heat the wire to the "critical" point.

The Rushmore generator is of the ironclad bi-pole type, as shown in Fig. 3. The field ring is a plain cylindrical tube of electrically welded steel, inside which are bolted the two steel pole pieces. These pole pieces are simply sections cut from a steel bar cold drawn to exact shape and require no finishing. The field coils are of flat copper wire, wound in formers and afterwards bent so as to fit snugly the interior of the field ring. Each coil consists of two windings, the first being the field coil proper and the second, consisting of a number of turns wound on top of the first, forming an auxiliary coil, which operates in opposition to the main field coil. The armature is of the ordinary slotted type running on ball bearings fitted in the brass end castings, one of which also carries the two carbon brushes. Two lugs are provided when it is desired to bolt the machine to a flat surface, but these are removable so that a strap fastening may be employed such as is used in magneto fixture. This latter method

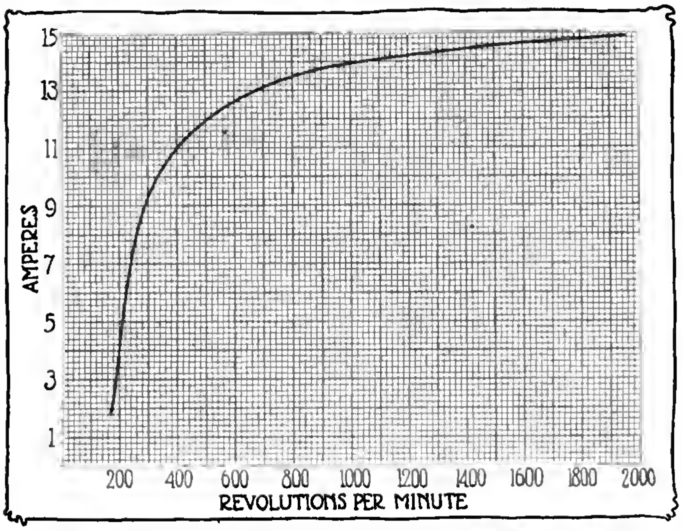

Fig. 1—Curve of output of Rushmore dynamo at various armature speeds

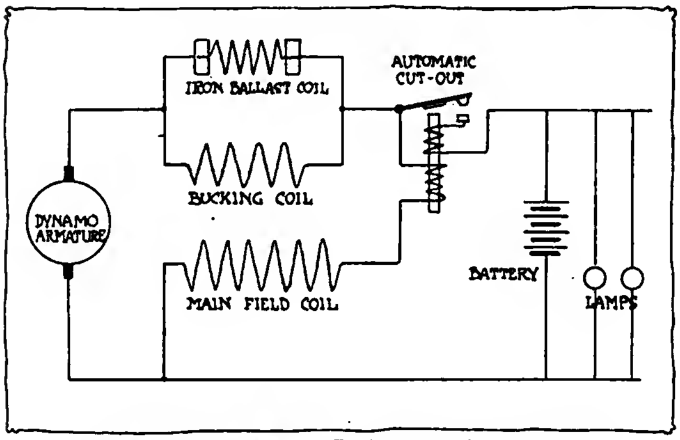

Fig. 2—Wiring diagram Rushmore lighting system

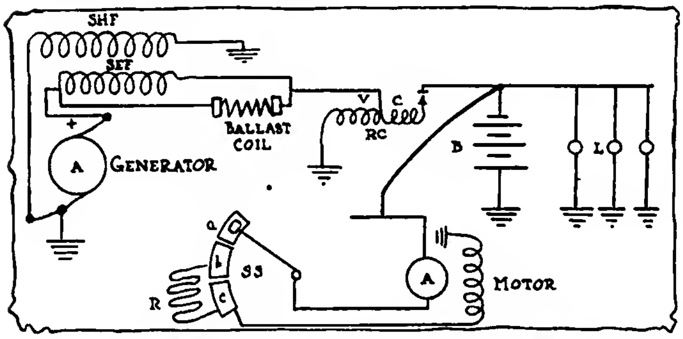

Fig. 3—Wiring diagram of Rushmore system with electric motor

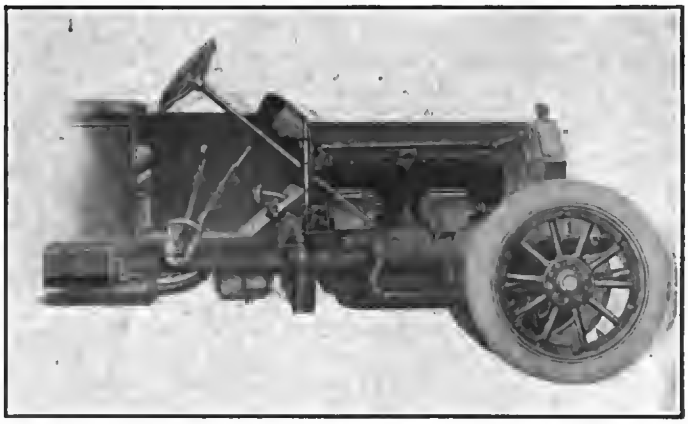

Fig. 4—Example of a Disco starting and lighting installation

requires a cradle type of bracket to fit the curvature of the magnet casing.

A small rectangular box fixed to the top of the casing contains an automatic cut-out, the purpose of which is to connect the generator to the battery when proper speed is reached, and disconnect it when the generator voltage falls below that of the battery. It consists of a double wound coil surrounding a short iron core, above which is pivoted a small iron armature. When this latter is attracted against the action of a spring, by means of current flowing in the coil, two switch contacts of silver are brought together completing the circuit from the generator to the battery. This cut-out, together with the iron resistance, mentioned above are the only regulating devices used. The latter is mounted on a small switchboard located on the dash and containing also the lighting switch and a fuse for the field coils. Owing to the heat generated in the iron wire and the necessity of allowing it to dissipate readily the wire is wound on a star-shaped insulator of a special asbestos compound, and surrounded by a ventilated cover permitting free circulation of air about the wire.

The technical term applied to this resistance is that of a "ballast coil." Its function may be seen by reference to the diagram of wiring Fig. 2. The ballast coil is shunted across the differentially wound coils on the field magnets. In other words, any current passing from the upper dynamo brush has two paths open, one through the ballast coil and the other through the secondary field winding. This latter is called a "bucking" coil. When the generator is running slowly the current flowing from the brushes is not sufficient to heat the ballast coil, which therefore provides an easy path, practically short-circuiting the bucking coils, and allowing the main field winding to fully magnetize the field magnets. The dynamo is now running as a simple shunt machine and its output increases with the speed, until sufficient current is generated to energize the fine winding of the automatic cut-out. This device is set to operate at a dynamo speed of 300 to 400 revolutions per minute, when the dynamo is furnishing current at about 7 1-2 volts. The current is now flowing through the series winding of the cut-out and thence to the battery and lights, furnishing the current necessary to light the lamps and also keep the battery fully charged. If the motor is raced the high voltage of the current generated raises the temperature of the iron ballast wire and so forces a quantity of current around the bucking coil, thereby reducing the magnetizing power of the main field, with a lowered output as a result. This output is practically constant. Its exact nature can be seen in the curve of Fig. 1, which has been taken from the Rushmore No. 2 generator.

When the car stops or is slowed down so that the generator is not supplying a sufficiently high voltage to overcome that of the charged battery the current from the latter passes in a reverse direction through the series coil of the automatic cut-out, releasing its armature and so disconnecting the generator from the main line. The lamps are then supplied from the battery alone.

The switchlock, intended for location on the dash, contains, besides the main switch, the iron resistance unit, a small fuse for protection of the field coils, and all the terminals necessary for wiring up to the lamps.

An incidental but important feature of this generator is its complete freedom from sparking at the brushes. This is of great practical importance, since a dynamo otherwise satisfactory, if it sparks, must have frequent attention to clean and occasionally sandpaper or true up the commutator, a job for which the average owner has neither the skill nor inclination. The exact reason for this absence of sparking is a little obscure, though the fact has been fully demonstrated. It appears to be connected with the location of the bucking coils which evidently have the effect of neutralizing the slight excitation which would otherwise arise in the coils short-circuited by the brushes.

Rushmore generators are supplied in two sizes, the smaller, No. 1, being 5.5 inches diameter by 8 inches long and weighing 23 pounds. Its capacity is 12 to 16 amperes at 6.5 volts. No. 2

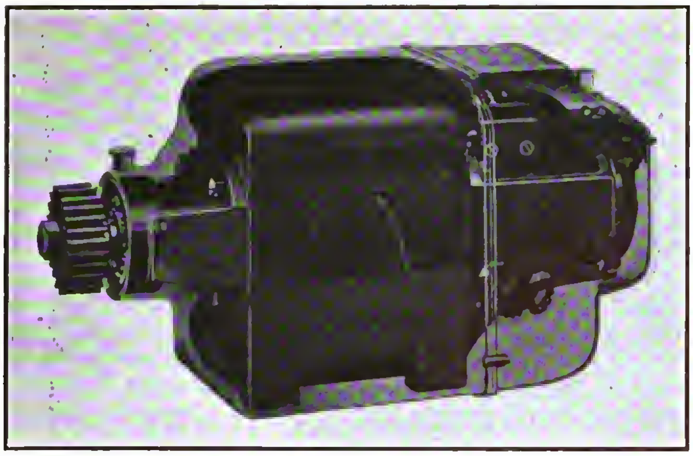

Fig. 5—View of Disco generator, showing armature and commutator

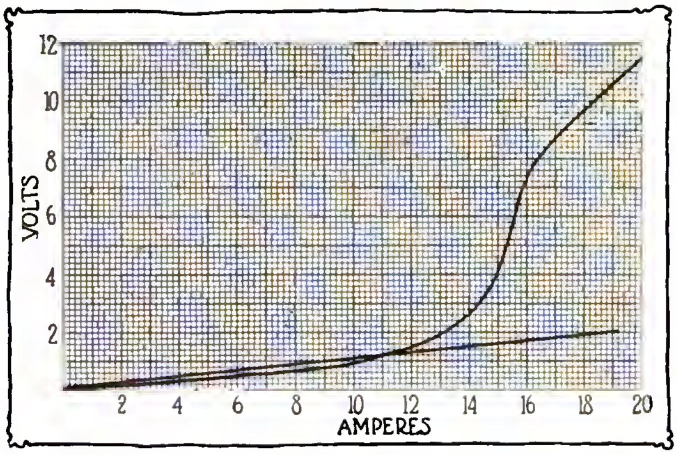

Fig. 6—Showing sharp rise of resistance of iron wire as compared to German silver

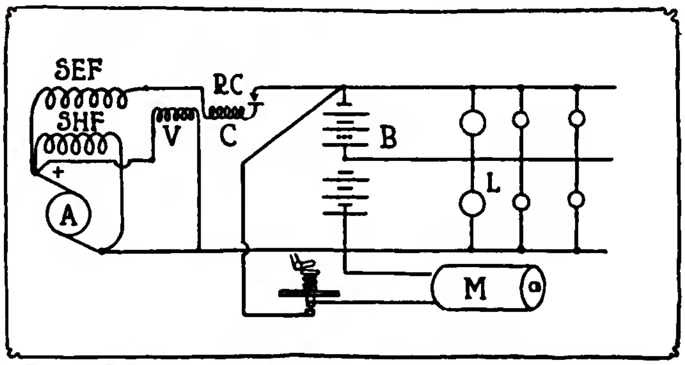

Fig. 7—Disco wiring diagram, showing series and shunt fields

dynamo measures 6 inches diameter by 10 inches long and supplies 15 to 18 amperes at the same voltage.

The cranking motor operates directly on the flywheel without intermediate gears. A pinion keyed rigidly to the end of the armature shaft meshes with a gear on the rim of the flywheel. The pinion is normally out of engagement. The pinion is engaged when it is desired to crank the engine and becomes automatically disengaged when the engine picks up and runs under its own power. There is no mechanism in the cranking part of the system outside the simple series motor and the starting switch. The armature is held normally out of line with the pole pieces by a coil spring acting against the armature shaft. The second point on the starting switch causes the fields to become energized sufficiently to draw the armature into line against the pressure of the spring. The next point on the switch the motor starts to rotate slowly, making it mesh firmly with the flywheel. The fourth point on the switch allows the motor to rotate at full speed.

When the engine starts the counter electromotive force or the electric flow in the opposite direction to that passing through the motor, neutralizes the fields and the result is that the coil spring forces the pinion out of engagement with the gear on the flywheel and the cranking motor comes to rest.

To further describe the motor it may be stated that it is of the iron clad type with a steel shell 7 inches in diameter, and four drawn steel poles on which the field coils are slipped after being wound on forms. Several hundred meters will be drawn on the jump in this system, owing to the small voltage used. Large cables and absolutely tight connections are necessary in order to reduce voltage drop through these connections.

Disco—Three Separate Units

The Disco electric lighting, electric cranking and ignition system is in three units. It consists of separate electric generator, separate motor and an optional make of ignition, the mounting of which units in connection with an engine may be made to conform with the dictates of the engineers on whose design they are placed.

The Disco electric generator and cranking motor work at 12 volts and are the same size, the aluminum cases being interchangeable for either unit. The windings are, of course, different, the motor being series and the generator compound wound. These instruments are made in two sizes, known as models 3-E and 5-E, the latter being the smaller for smaller engines. The total weight of the generator and motor of model 3-E is 70 pounds, while 5-E weighs 50 pounds.

The system may be used in connection with any storage battery equipment desired, provided it is of sufficient capacity to do the work.

The electric generator begins to generate energy which it sends to the storage battery when the speed of the engine has reached a speed corresponding to about 7 miles an hour of the car when running on direct. Below this speed of the engine the automatic cut-out switch does not operate to make connection between storage battery and generator, thus preventing the storage battery from discharging back through the generator when the engine is running idle or at very low speed. At car speeds above 25 miles an hour the generator is again automatically cut out, the charging curve being therefore between the limits of 7 and 25 miles. It reaches its highest point at about 15 miles an hour. This charging range may be varied, however. Below 7 miles an hour, and when engine is not running, lighting current comes from the storage battery.

The electric motor may be so placed as to drive through the flywheel by means of teeth cut in the periphery of the latter with which the teeth of a pinion mounted on the motor armature shaft mesh. Or the motor may be so mounted to drive through the timing gears or special gears at the front end of the engine. The preferred mounting, however, is the placing of the electric motor and generator on opposite sides of the engine and at the forward end so that they are driven, or drive, as the case may be, through some sort of connection with the front gears.

When mounted in connection with the timing gears, the Disco electric motor drives through a roller clutch which cuts out as soon as the engine starts. When the driver makes electrical connection between the electric motor and the storage battery through a switch it causes the cranking motor to operate, revolving the crankshaft until the engine takes up its own cycle. As soon as this happens a roller clutch automatically breaks the driving connection between the electrical unit and the engine, and providing the operator has released the switch, the electric cranking apparatus comes to rest.

The amperage required for starting depends upon the installation, upon the stiffness of the engine and upon the compression pressure. It is therefore difficult to give any definite figure for this. It has been found, however, that 60 amperes are required to turn over a Haynes 4 1-2 by 5 1-2-inch engine at 120 revolutions per minute. Another engine of larger dimensions—4 7-8 by 6 inches—drew 90 amperes for starting. These pressures are

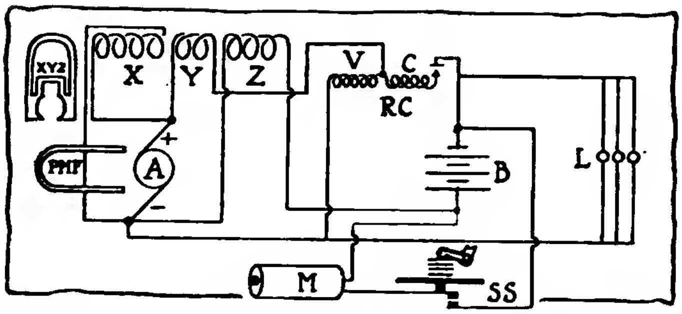

Fig. 8—Wiring diagram of the Esterline cranking and lighting system

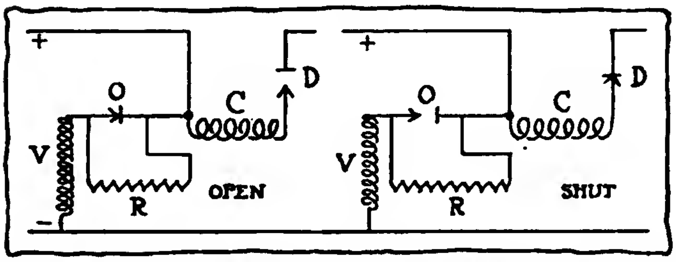

Fig. 9—Esterline reverse current cutout diagram, showing how the current is automatically interrupted when flowing in a reverse direction

only momentary, however, lowering immediately the moving parts of the engine are got under way. No compression release is used in connection with the cranking apparatus, it being so designed for each installation that it will work against full compression. The lamps are wired on the three-wire system and operate at 6 volts.

The reduction ratio between electric motor and engine depends upon the installation, but in the average case about twenty to one would be used. With this gearing an average four-cylinder motor should be cranked at about 150 revolutions per minute, while in the most extreme case the electric motor would turn the crankshaft at about 114 revolutions per minute.

If specially desired, the Disco system may be made to combine ignition along with its other electrical functions. In this case the electric ignition current comes direct from the storage battery. A coil is used, it being a low-tension arrangement. The ignition part, it will be seen, has only the storage battery in common with the rest of the apparatus.

Esterline—Made in Three Sizes

The Esterline is a three-unit system, having the generator, electric motor and magneto as entirely separate units. The electric motor is geared to the flywheel in the typical layout by means of a pinion on a roller clutch. When the speed of the gasoline engine equals or exceeds 100 revolutions per minute the roller clutch comes into action and the electric motor is disconnected from the engine. The generator is preferably driven by gearing or silent chains and is made in three sizes, differing only in the speed in which they operate. The largest machine operates at 1.5 crankshaft speed, the next size at double the crankshaft speed and the next size at 2.5 crankshaft speed. The entire system operates at 6 volts using a three-cell storage battery.

A simple series-wound motor is used. With this type of winding the turning moment, or torque, of the electric motor increases with the load, this being a condition which is rendered necessary by the function of cranking the engine.

The generators made by the Esterline company are built under the Berdon patents. The electro-magnetic field, which is combined with the permanent magnet field, has a shunt and differential windings, X, Y, Z.

The amount of current drawn by the starting motor in turning over an engine will depend altogether upon the size of that engine, the amount of compression, the temperature of the atmosphere and the rate at which it is revolved. Taking a four-cylinder motor of average dimensions the ammeter will register 160 initial starting current with a running current of 115 amperes. On a six-cylinder engine having a bore of 4.5 inches and a stroke of 7 inches the initial starting current was about 250 amperes and the running current 140. A compression release is not necessary with any starter. Two gear ratios between the motor and the engine flywheel can be furnished. One is sixteen to one and the other thirty-two to one, both being with herring-bone gears for silence.

The storage battery usually furnished by the Esterline system has a capacity of 120 ampere-hours at a discharge rate of 10 amperes. The length of time a motor may be spun by this battery depends, of course, on the power required to revolve the engine and the temperature conditions. On a medium-sized four-cylinder motor at about 65 degrees Fahrenheit the gasoline engine can be spun 45 minutes to an hour and a half. On the large six-cylinder motors the time is reduced to 30 or 45 minutes. The operation of the starter consists of pressing a foot button on the dash, which shifts the starting gears and closes the starting switch. The switch is of the laminated copper type, having a large conducting area.

Remy—Makes Any Type Desired

Remy makes any desired type. In the main the line consists of three interchangeable systems, a three-unit, two-unit and single-unit being produced. All these systems work at 6 volts and are interchangeable in that respect. The method used in mounting the various units in the Remy system is left to a large extent to the automobile manufacturer, and a special installation is used to suit each particular case. The generator is shunt wound and has the third brush regulation, which is common in lighting work. The generator is made in two styles, one including the combination timer and distributer for ignition purposes; the other without. Where magneto ignition is not desired the first type can be used, while with the magneto the ignition attachment will not be necessary. The generator starts to charge the battery at an armature speed of 200 revolutions per minute. Between 200 and 1,100 revolutions per minute where a maximum amperage is attained the charging rate is almost constant. Above this point the charging rate drops off. With the third brush regulation, in which advantage is taken of the distortion of the magnetic field at high speeds, the voltage is kept practically constant throughout the operating range. A reverse current cut-out prevents the battery from discharging through the generator when the car is at rest.

The cranking motor is simple series wound, whether it is single unit or incorporated in the two armature motor-generator. The installation of the cranking motor depends entirely on the engine to which it is supposed to be attached, but as a rule the motion is transmitted through reduction gearing in connection with a roller clutch. The cranking motor is meshed with the gearing when the starting switch is first thrown in, and then, upon the full application of the switch, cranks the motor. Battery used with this system is optional with the manufacturer, who may go as far as he likes in the matter of weight. One feature of protection which is unique on this system is the fuse, which takes care of the generator. Should the wires from the battery be severed the excess voltage would not burn out any part of the circuit except the fuse.

Auto-Lite—A 6-Volt System

The Auto-Lite is a three-unit system, the cranking motor, generator and magneto each being a separate and distinct unit. The system works at 6 volts, the motor, generator and magneto each operating at a current of this potential.

In the average installation the generator is driven from the crankshaft by a silent chain; the gear reduction between the generator and the crankshaft of the engine is two and one-half to one. The principal dimensions of the generator are as follows:

Generator base height	2.125	inches
Generator width	4.5	inches
Generator length	10.5	inches

The output is regulated by means of a slipping clutch and centrifugal governor. In this clutch the operation is entirely automatic. The weights fly apart and in doing so decrease the pressure between the frictional surfaces and allow one to slip over the other, thus decreasing the speed of the drive. This arrangement prevents the output of the generator from rising to a point where it would harm the storage battery.

In order that the battery cannot discharge back through the generator when the car is standing idle, a reverse current cut-out is used. This is of the magnetic type and is controlled by a voltage coil only. When the voltage of the generator falls below that of the storage battery the circuit is automatically broken by a spring which pulls the relay armature away from the magnet as the current becomes weaker, thus breaking the line between battery and generator. The operation of this type of reverse current output was explained in last week's issue and in this connection the hydraulic parallel drawn between the entire system and the lighting and starting system should be studied. The reverse current cut-out was compared to a ball check. In the Auto-Lite system it is housed between the magnets of the generator.

The cranking motor weighs 33 pounds. It is series wound and runs at from twenty-five to thirty-five times the crankshaft speed. The reduction gearing may be by spur gears, silent chain or worm or a combination of two or more. A roller clutch is used to disconnect the starter and its train of gears when it is not in use. After the engine has been cranked the control switch is thrown off and allows the electric cranking motor to come to rest until again needed.

Generally a 6-volt, 120-ampere-hour storage battery is used with this system. On two installations, an Abbott and a Jackson, where the motors were 5.5 and 5.25 inches respectively in stroke and 4.5 inches bore each, the starting motor turned the Abbott at a rate of 80 revolutions per minute and the Jackson at 88 revolutions per minute at gear reductions of thirty-five to one and thirty-three to one respectively.

Entz—Employs Motor-Generator

The Entz cranking and lighting system employs a motor-generator and is hence in the two-unit class. The motor-generator is mounted on the side of the gasoline motor and in one of the most prominent installations of this system is connected directly to the crankshaft of the motor by a silent-chain drive. The motor-generator is constantly rotating. The winding on the armature is such that at car speeds below 10 miles per hour on high gear it acts as a motor and is helping to propel the vehicle. Above this speed it acts as a generator and charges the storage battery, which is so designed that it cannot be injured by an overcharge, the decomposition of the electrolyte being the only result of a long-continued overcharge. The system operates at 18 volts and takes care of the lights as well as the starting apparatus in the customary way. The reduction between the electric starting motor and the gasoline engine is, in the customary installations, 3 to 1 on a 4 by 4-inch six-cylinder motor, and 2.6 to 1 on smaller motors. No compression release is used on this starter. In the early day of the electric starter this was more or less of a necessity with many of the systems, but it may be stated that through the gamut of starters now on the market which rely on electricity for their motive power there are none which require a compression release. To operate the starter a knife switch with a large handle located on the dash is pushed down. This connects the battery to the motor-generator which at this time acts in the capacity of an electric motor and turns over the gasoline engine at a speed of about 80 revolutions per minute. This is sufficient speed to allow the motor to be started on the magneto. The switch is then left down. When the speed of the gasoline motor becomes higher than necessary to drive the car at the rate of 10 miles an hour on high speed the motor-generator begins to fill the office of a generator and supplies current to restore that drawn from the storage battery for the purpose of starting the gasoline motor or for restoring the current used by the lights when the car is standing idle or when running slowly. In mid-position the generator is disconnected.

Deaco—Adds Motor to Lighting System

The three-unit system which has been added to the Deaco line of automobile electrical apparatus is incorporated with the lighting system in so far as the storage battery, which is charged by a lighting generator, furnishes current to an electric motor when the latter is used for cranking the automobile engine. The combination system of starting and car lighting consists essentially of a motor, a generator, an automatic cut-out switch, a control switch, storage battery and lamps. The starting system proper takes in the storage battery, control switch and electric motor.

The electric motor is connected to the engine in one of two ways, one being through silent-chain connection with the crankshaft at the front of the motor and the other through gearing meshing with teeth cut in the flywheel face. In the first case the chain sprocket mounted on the crankshaft contains a floating clutch which automatically releases the driving connection between the electric motor and the crankshaft when the engine begins to run under its own power, allowing the starting apparatus to come to rest.

To operate the cranking system, the driver simply makes the electrical connection between the storage battery and the electric motor by closing the control switch. This sets the motor in operation, turning the crankshaft through the silent-chain connection. The floating clutch takes care of the apparatus once the engine starts. Then the control switch is thrown off, allowing the starting motor to come to rest.

In the application of the starting motor to the flywheel, a roller clutch is used, the gear of which engages with the flywheel teeth on the pressure of a pedal on the floor board of the car. After connecting the gearing, the electrical connection is made the same as in the other method of mounting, the working of the device being the same.

The motor is geared 18 to 1 to the engine in the silent-chain

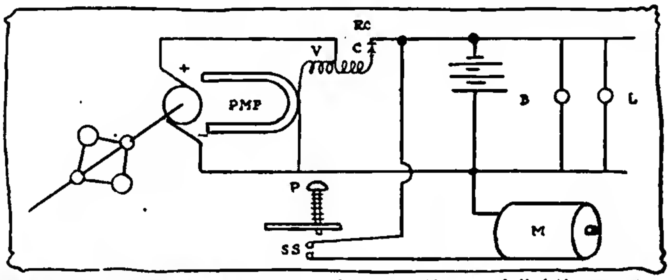

Fig. 10—Wiring diagram of Auto-Lite starting and lighting system

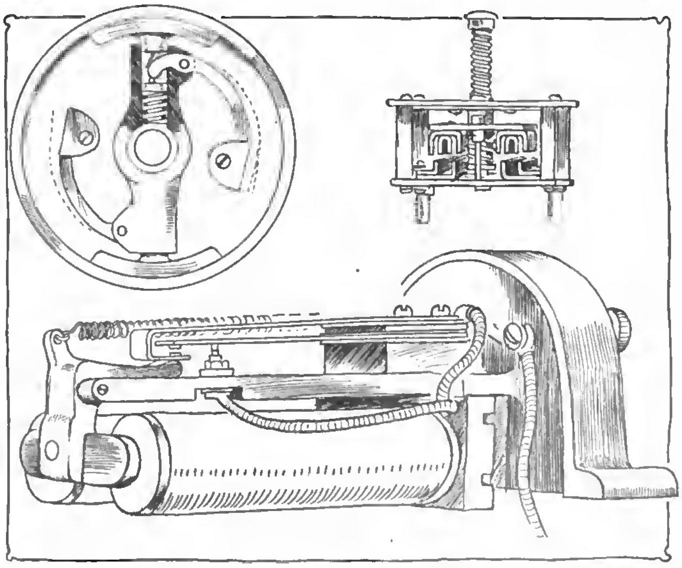

Fig. 11—The Auto-Lite control mechanism for regulating generator output

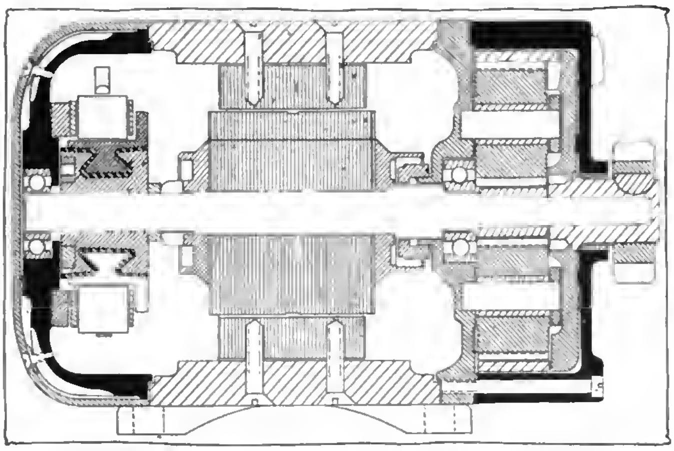

Fig 12—Section through the Deaco electric generator

arrangement, and will usually crank the engine when running at 1,500 revolutions per minute, which means an engine speed of about 85 revolutions per minute. The electric motor measures 10 inches in length by 6.75 inches in diameter.

The weight of the starting apparatus exclusive of battery is 60 pounds. The battery used is a Willard 6-volt and 120 ampere-hour type. It weighs about 69 pounds.

The starting motor draws from 150 to 200 amperes at 6 volts in starting an engine. This amperage is only momentary, for when the engine begins to get under way the high initial torque required to start the moving parts, due to their inertia, is overcome, and only 100 amperes are drawn to revolve the crankshaft until the engine picks up its own operation.

No compression release is necessary with the system. The motor and generator being mounted on opposite sides of the engine, they balance. A section through the center of the Deaco generator is given in Fig. 12. Note armature shaft mounting.

The automatic cut-out is installed in the circuit between the generator and the battery. It acts as a circuit-breaker to prevent the current which has been stored in the battery from discharging back through the generator when the engine is standing still. When the latter is started and the generator voltage is slightly greater than that of the battery, the cut-out established connection, allowing current to flow from the generator to the battery. But when the generator slows down so that its voltage drops below that of the battery, the circuit is automatically broken.

When the motor is not running so as to cause the generator to furnish current for the lights, the energy comes from the storage battery. But at high speeds the generator supplies the lights direct. At intermediate speeds when the current generated is not alone sufficient for the lights, the generator is assisted by the battery. This is all automatically regulated by the cut-out switch.

Adlake—A Three-Unit Type

The Adlake electric cranking and lighting system is made by the Adams & Westlake Company. It may be classed as one of the three-unit type as it consists of a generator and an independent motor. The ignition system is optional with the user.

The system is designed to operate at 6 volts both in starting and lighting. It has a new generator which is a simple, shunt-wound machine of large capacity with a two-pole laminated iron field. The older machine did not possess a laminated field. The latest machine carries its load at a slightly lower speed and yet weighs only 38 pounds instead of 48, as formerly. The generator is driven at engine speed and has capacity sufficient to carry the lighting load at about 325 revolutions per minute.

The system consists of a 6-volt generator, a three-cell, 6-volt storage battery, a field regulator and a series motor. The field regulator, the circuit breaker and the action of the headlight switch are the features of the system.

Regulation is obtained by varying the amount of resistance in the shunt-field circuit. As the current output increases resistance is added in the field circuit thereby cutting down the current therein and reducing the output of the machine. This is effected by the controller, Fig. 14. This consists of a wheel over which passes a flexible cable. To one end of the cable is attached a weight W to the other end a soft-iron cylinder S. To the wheel is fixed an arm with a brush V moving over the resistance contacts. When V is moved in a clockwise direction it adds resistance, thus cutting down the output of the generator. It is caused to move in this direction by the action of the electric current passing through the two coils a and b, which pull the soft-iron cylinder S downward. As the coils a and b are in series with the line they exert a pull which is always proportional to the output of the generator.

It will be noted that there are two coils. When the headlights are not burning both coils pull on the regulator and hold the output to 6 amperes, for example. When the headlights are turned on one of the coils is cut out. As the coils are the same size, this cutting out of one coil reduces the pulling power to one-half and as a result the generator practically delivers twice as many amperes as before or 12 as compared with that above.

What this variation in output means may be summed up as follows:

Output, Amperes	Lights	Charging rate, Amperes	
6	All out	6	Day running condition
6	Side and tail	1½	City running at night
12	All lamps	1½	Country running
12	Side and tail	7½	Winter work

The object as outlined in the first three conditions is to maintain a fairly low rate of charge when no lights are burning, as during the day. The second object is to maintain the same charging rate when the headlights are burning as when the side lights are lit. The last condition is that of driving in winter when the user of the car does little touring. He will therefore scarcely balance the demand for electricity caused by the longer hours of darkness which comes with the long winter evenings.

The circuit breaker in this system takes the place of the reverse current cut-out. It consists of two pairs of coils, one pair, the voltage coils, being permanently fixed, while the current coils are mounted upon an armature which closes the current switch. Their action is identical with that of any reverse current cut-out. The voltage coil first causes the closing of the relay. As soon as the current starts to flow through this relay from the generator to the battery the series coils of the relay are excited and help to keep the relay closed. On the other hand, as soon as the battery current starts to flow back through the relay to the generator, which happens when the motor is stopped. the series and voltage coils are repelled, thus opening the circuit and preventing the battery from discharging through the generator.

The Adlake starter consists of a cranking motor and suitable gearing to connect it with the flywheel. The reduction from motor to crankshaft is twenty to one. The starting motor weighs about 40 pounds and may be located wherever the automobile manufacturer desires to put it. It takes about 80 to 120 amperes when cranking a motor. this rate depending on the size of the motor to be cranked. Its application to some standard motors will be shown in a subsequent issue.

Elyria-Dean—Slow-Speed Generator
